THE

JOURNAL OF HORTICULTURE,

COTTAGE GARDENER,

AND

HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

EDITED BY JOHN WRIGHT, F.R.H.S.

Established

in 1848.

VOLUME XXXIV. THIRD SERIES.

JANUARY — JUNE, 1897.

LONDON:

PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

LONDON :
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

"Change yet no change," however seemingly paradoxical, would scarcely be an inappropriate motto expressive of the actualities of the past and present of the *Journal of Horticulture*.

Full of years and honours, its venerable and venerated proprietor, the late Dr. Hogg, was called to his rest nearly midway (March 18th) of the term covered by the ninety-eighth half-yearly volume just completed.

On the occurrence of that melancholy and memorable event great was the responsibility which fell on his successor—involving as it did the maintenance of a periodical which has long proved a "welcome guest" in the homes of amateurs and gardeners over the length and breadth of the old home-land and other parts of the empire beyond the sea—a responsibility shared in degree by the writer of the last forty-three prefaces associated with the indexes to the volumes, and of the present lines.

The old chieftain—always thoughtful and looking to the future—left to others during his later years the production of the weekly issues of the organ that he did so much to establish; and it is now gratifying to be able to state that under his genial inspiration the *Journal of Horticulture* became so deeply rooted—like a healthy tree—as to pass unscathed through a time of trial incidental to the change—the termination of a life—that was felt to be approaching.

Thanks to the love and loyalty of its readers, and to the ability and zeal of its contributors, the favourite gardening weekly of so many has attained to the full all that the great lost leader could have anticipated; even more than this could in truth be said, but the fact recorded is enough.

There has been no change, at least prejudicial to the acceptability of "Our Journal." Its character and tone have remained the same. The spirit of the past has pervaded its pages, and the same spirit will continue—a spirit of endeavour to make the pages of the future interesting and instructive—refreshing after the toil of the day, helpful in the work of the morrow: a spirit of kindly feeling towards all who love gardens and who are striving to make them more lovable still; and, not least, a spirit of warm appreciation of the co-operative effort and valued help so freely rendered by a host of friends.

For what those who are responsible for the production of the *Journal of Horticulture* have been so far able to accomplish they are deeply grateful. Supported by the constancy of old readers and writers, and encouraged by new recruits in both sections, the hope is, as time goes on, to do still more on well-considered lines and in accordance with the sound principles of steady, progressive growth.

The desire is to afford such aid as may be needed by the inexperienced, and in cases of difficulty generally; and those readers who do not find in the weekly issues the precise information they require are cordially invited to promptly make known their wants (with conveniences for meeting them), and such advice as long experience can impart will be tendered freely—not as an irksome task, but an agreeable duty.

The wish is to fully reciprocate the favours of clients and supporters, and to do what is strictly just and right to all who are animated by the same spirit towards the *Journal of Horticulture*. By acting in accordance with that principle, the justice of which cannot be impugned, results may safely be left to the future.

INDEX.

- Abietene, the source of, 529
 Acacia cultriformis, 131
 Achimenes, culture of, 387
 Aconite, Winter, the, 92
 Across the Channel, 503
 Acerides, notes on, 417; *A. vandarum*, 417
 Aldershot, The Royal Pavilion, 561
 Alpine flowers, brief notes on, 7, 92, 215, 320, 439
 Alterations, 307
 Amaryllis, at Chelsea, 299; or *Hippeastrums*, 501
 Amelanchier canadensis, 348
 American blight, remedy for, 8, 347
 Ammoniacal liquor, for disinfecting soil, 42; and wire-worm, 84
 Anemone, fulgens unsatisfactory, 283; coronaria The Bride, fl.-pl., 505
 Annals, half-hardy, 162
 Annus memorabilis, 332
 Anoisanthus breviflorus, 95
 An old and fruitful garden, 185
 Anti-blight powder, 283, 317
 Antirrhinums, 334
 Aunts, methods of destroying, 468
 Aphid, woolly, the, 347, 434
 Apples—judging at the Crystal Palace, 13; disqualifying at shows, 13; classification of, 13, 29; cooking and dessert Apples, 13; keeping Apples, 13; in a Gloucestershire Apple orchard, 54, 98; twigs and branches destroyed, 84; thinning, 137; Jolly Beggar, 149; cider, 180; insects on twigs, 282; the Apple blossom weevil, 338; late, 341; Easter Orange, 409
 April characteristics, 371
 Arabis albidia, 186
 Arsenate of lead, 338
 As of a dream, 224, 345
 Asparagus, forcing, 163; culture, 357; ingredients of ash, 431; English, 540
 Astelma eximium, 21
 Aubrietias, 334; *A. purpurea*, 334; propagating, 468
 Auriculas at the Drill Hall, 336; northern show, 393
 Avery Hill, 406
 Axes to grind, 263
 Azalea—indica alba, 251; mollis hybrids, 540
 Bees—hives with ten standard frames, 19; the doubling system, 19; an English bee-keeper at home, 20; work for the New Year, 42; starting bee-keeping, 63; when to commence, 63; hives with ten standard frames, 63, 83; using old combs, 83; system in bee-keeping, 83; honey and hives, 83; pure honey, 105; storing honey, 105; the weather, 125, 492; enemies of bees, 125; making candy, 125; doubling hives, 126, 169; gazing sections, 147; packing sections of honey, 148; large hives, 169, 281, 327, 375, 445; mice in hives, 170; questions on bee-keeping, 191; bees swarming, 191; how to prevent swarming, 192; giving empty frames to obtain a surplus, 192; feeding stocks with candied honey, 192; queenlessness, 219; uniting weak colonies, 220; wintering 240; dampness in hives, 240; reducing entrances, 240; doubling hives, 240; flowers for, 261, 421; fertilisation of fruit trees, 260; examination of stocks, 281; drones in hives, 282; spring dwindling, 304; oven air feeding, 304; best hives for wintering, 326; late breeding in autumn, 326; straw skeps, 327; spring feeding, 351; large frames, 375; number of bees in a hive, 375; two queens in one hive, 399; 350 lbs. of honey in one hive, 399; cleansing combs, 399; removing spare combs, 421; spreading brood, 421; fallacy in bee-keeping, 445; dead bees, 445; dividing a stock, 445; "The Bee Master" 445; working for comb honey, 467; preparing for the honey harvest, 492; notes from Devon, 492; working for extracted honey, 516; prevention of swarming, 516; comb honey, 516; early swarms, 539; swarming *versus* non swarming, 539; transferring stocks, 539
 Begonias—Gloire de Lorraine, 48, 95; tuberous-rooted, from seeds, 90; growing, 133; Gloire de Sceaux, 274; insects eating seedling, 327
 Belvoir, spring flowers at, 462
 Berberis stenophylla, 364
 Berlin International Horticultural Exhibition, 230, 381
 Berwick Hall, 296
 Birmingham notes, 435
 Borecole, Sutton's Al, 340
 Boronias, propagating, 468
 Boswell, Mr. H., death of, 117

 Domain, young gardeners'—A good beginning, 17; Gardeners' Royal Benevolent Institution, 17; Calanthes, 17, 301; the R.H.S. examinations, 17, 38, 101, 122, 144, 166; Vine pruning, 38; Eucharis amazonica, 38, 489; early forcing of Peaches and Nectarines, 38, 60; tool house and tools, 60; mice and Cinerarias, 60; Poinsettias, 60; the Black Currant, 61; winter Tomatoes, 61; Eucharis culture, 79; Cyclamens, 80, 167; keeping a diary, 80; herbaceous Calceolarias, 81; taking Chrysanthemum cuttings, 80; Vine culture, 80, 102; winter flowering Carnations, 80; potting, 101; potting Cattleyas, 101, 122; growing and forcing Lily of the Valley, 102; conservatory management, 102, 122, 145, 188, 280, 436; Dracæna, 102, 257; Gloxinias, 102, 144, 189, 237, 390; observation, 103; testing early Tomatoes, 122; the Victorian Era Fund, 122, 166; Azaleas, 122; single Dahlias from seed, 122; Vines, starting to flowering, 123; Chrysanthemums, 145; Strawberries for forcing, 145; Grape Vines, 145; tuberous-rooted Begonias, 145, 256; Fœesia refracta alba, 166, 279; notes on Lapagerias, 166; Imantophyllums, 166; Gloriosa superba, 167; Primula obconca, 167; notes from a Coffee estate, 167; Begonia Gloire de Sceaux, 18; Croton culture, 189; Snowdrops, 189; young gardeners' examinations, 217; Streptocarpus, 217; the culture of Arum, 217; the Strawberry, 217; Adiantum cuneatum, 218; notes on Vines—thrips and rheumatic, 236; Polyanthus and Primroses, 236; Vines at Penrhyn, 237; pruning, 237; Carnations, 237; Vines—setting and thinning, 259; Fuchsias, 279; Salvias, 279; Raspberry culture, 390; forcing French Beans, 391, 349, 419, 442; the Banana, 391; Cannas, 391; Chimonanthus fragrans grandiflorus, 391;

DOMAIN, YOUNG GARDENERS'

—continued.

Mignonette, 301; early flowering Chrysanthemums, 301; notes on Pines, 302; the double white Primula, 324; the herbarium, 324, 349; a well-kept garden, 324; Primula culture, 324; forcing Lilac, 325; Dipladenias, 349, 372; culture of Bonvardias, 372; Crotons, 372; Enphorbia jacquiniiflora, 372; Amaryllis, 396; Violet Marie Louise, 396; the Melon, 396, 419; early fruit houses, 397; Violets, 419; Bonvardias from root-cuttings, 419; the Apple, 419; Geraniums for winter, 442; notes on Dahlias, 442; hanging baskets, 442; Nature's garden, 442, 464; Cinerarias, 443; Gold pen-men, 464; Ixoras, 464; Zonal Pelargoniums, 464; stove climbers, 464; packing, 489, 513; Tomato culture, 490, 513; propagating Euphorbia jacquiniiflora, 514; summer bedding, 537; Melons in frames, 537; Dendrobiums, 538.

Do plants think? 255

Douglas, Mr. J., presentation to, 324

Dream, as of a, 224, 345; Stanton Lacey Vicarage in 1837, 225

Drill Hall difficulties, 331

Dublin-by-the-Sea, 313

Earthworms, 529

Earwigs flying, 338

Eaton Hall, spring bedding at, 485

Edelweiss, 8

Eelworms—eradication of, 118, 134; and Tomatoes, 195

Electricity and seed germination, 181

Endive, cooking, 100; culture of, 120, 159

Epidendrums, notes on, 530

Epidendrum failing, 328

Eucharis Stevensi, 10

Euphorbia cyparissias, 7

Euryclis Cunninghami, 327

Evolutionary essays, 369

Exhibitions, memories of, 143

Exhibitors and railway fares, 16

Exochorda grandiflora, 483

Experimental work in horticulture, 519

Fadyenia prolifera, 540

Farm-gates, 21; the Agricultural Rating Act, 44; economy with efficiency, 65; preparing for the lambing season, 85; poultry and eggs in 1896, 167; poor soil and best means of cropping, 168; the world's bread corn, 127; the manure heap, 149; large versus small farms, 171; liquid manure for grass land, 172; two parasites, 193; real old Cheshire, 221; cow keeping, 222; by the way, 241; churns, 242; Comfrey and Lupins for fodder, 242; wireworm, 261; Potatoes, what to plant, 283; calf dying, 284; who gets it? 305; notes by the way, 329; our poultry yard, 333; the Turnip crop, 377; till the doctor comes, 401; Ketlocks, 424; turnip cultivation, 448; spoiling good land, 470; the day of small things, 493; milk fever, 494; a serious complaint, 517; now and then, or 'tis sixty years ago, 541; chickens from eggs eighteen months old, 542; work on the home farm, 22, 44, 66, 86, 108, 128, 150, 172, 194, 222, 242, 262, 284, 306, 330, 354, 378, 402, 424, 449, 470, 494, 518, 542

Ferns, weevils on, 220

Fertilisers for the orchard, 79

Ficus elastica, propagating, 221

Figs, seasonable notes on, 18, 61, 146, 190, 238, 280, 302, 420, 514

Fish oil, 193

"Flights" as manure, 148

Floral facts and fancies, 12

Floriculture under difficulties, 142

Florists' flowers, seasonable notes on, 274

Flower beds, planting, 220

Flower garden, the, 41, 82, 125, 169, 238, 308, 373, 444, 515

Flower gardens of Victoria, the, 414, 475

Flowers—winter at Hindlip Hall, 16; hardy, notes on, 36, 133, 175, 246, 311, 358, 390, 472, 525; the mission of, 211; preservation of, 251; for schools, 310; of the streets, 335; cut, for profit, 423; in the house, 511

Following the leader, 1

Forcing, hints on, 53, 93, 112

Forests, Australian, 59

Forget-me-nots, 308

Formalin for the Potato scab, 270

Forsythias, 364

Foster-Melliar, Mrs., death of, 116

Frost, hoar, as an air purifier, 137

Fruit forcing, 18, 40, 61, 81, 103, 124, 146, 168, 191, 218, 238, 259, 280, 302, 325, 350, 373, 398, 420, 443, 465, 491, 514, 539

Fruit garden, hardy, 40, 81, 124, 167, 218, 259, 302, 350, 397, 443, 490, 538

Fruit—thoughts about fruit growing, 6, 26; advice on fruit trees—County Council teaching, 10, 39; gold medalists of the Fruiters' Company, 74; pruning maiden trees in pots, 85; pruning, a claim for, 75; Paradise Stocks for Western America, 106; fads about, 195; prospects round Liverpool, 290; variations of seedling, 245; grafting, 259; sale of fruit pulp, 271; hardy, bloom of, 340; fruit growing on chalk, 344; preservation, 371; destruction of by frost, 430; a reverie on, 432; seasonable notes on, 443

Fuchsias—propagating, 213; jottings, 215; leaves falling, 423

Gardeners, making more, 410, 435

Gardeners' Orphan Fund—annual general meeting, 164; annual dinner, 392

Gardeners' Royal Benevolent Institution, Worcester Auxiliary, 14; Victorian Era Fund, 46; annual general meeting, 53; anniversary dinner, 485

Gardening, picturesque, 475; for all, 480; the delights of, 430

Gardening scholarships, 75

Garden, my northern, in May, 476

Gardens, fair, dream of, 25; an old and fruitful, 135; extra help in, 379; our, 415

Garlic, a surprise of, 517

Gastrolobium villosum, 59

"Geraniums," double scarlet, for market, 422

German shows through English spectacles, 381; Berlin, 381; Hamburg, 382

Gilia Brandegei, 213

Gloriosa superba, 328

Gloucestershire Apple orchard, in a, 54, 98

Godetias, 423

Godinton Park, Ashford, Cyclamens at, 87

Gooseberry, green fly on, 260; foliage, sickly, and red spider, 418; bushes, bud and graft influence, 495

Grafting, improved method of, 430, 468

Graham, Mr. A., presentation to, 316

Grapes—Gros Colman, cracked, 85; Black Hamburg, breaking unevenly, 170; a novelty in Grape production, 205; Duke of Buccleuch, 226; setting, 355; ten commandments in thinning, 408; Vine mould on, 467; shanking fungus, 467; Muscat of Alexandria, insects on, 492

Grove Park, Kingsbury, the conservatory at, 291

Haberlea rhodopensis, 463

Hamburg show, 382

Hampton Court, 561; Gardens, 389; Mr. Graham's retirement, 52

Harborne Hall, 512

Head, Mr. W. G., death of, 293; the late, 316

Heliotropes, notes on, 289

Help, extra, in gardens, 379

Hepaticas, 76, 215

Hibbertia perfoliata, 371

Highbury, flowers at, 75

Hippeastrums, 329, 501

Hoeling, 412

Hogg, Dr. Robert, death of, 232, 248, 268, 291, 314

Holly hedges, 346; trees and their requirements, 401; leaves blistered, 540

Honesty, 224

Honeysuckle, scarlet, propagating, 541

Horticultural history notes—Memories of old Chiswick, 50; round about Marylebone, 288; along Western Middlesex, 498

Horticultural (Royal) Society's examinations, 26; Victoria medal, 45, 72, 99; members of Committees for 1897, 78; annual general meeting, 113; granting certificates, 162, 181, 212, 255, 290; Committees, 29, 112, 198, 254, 276, 321, 361, 418, 536; certificates and awards of merit, 29, 113, 199, 254, 322, 361, 418, 454, 536; Scientific Committee, 51, 137, 229, 275, 361, 392, 430; alleged luxury at the Drill Hall, 255; Drill Hall difficulties, 331; Temple Show, 449

Horticulture—experimental work in, 519; during the Queen's reign—sixty years' reminiscences, 566

Houses, arrangement of, for effect, 358

How trees are built, 111

Hyacinth, a prolific, 137

Hydrangeas, 266

Hypnum proliferum, 196

Ilex, aquifolium laurifolium longifolium, 94; crenata, 159

Implement for killing weeds, 42

Inglis, Mr., presentation to, 505

In honour of the Queen, 543

In search of sunshine—the city of the flowery plain, 408, 428; the leafy groves of Sans Souci, 473

Insects, white, in garden, 85; in soil, 126; on plants, 328; invasion, 385, 437, 479, 509, 535; destroying and preventing, 461

Ionopsidium acaule, 439

Ireland, notes from, 460

Irises Bakeriana, 177; Lorteti, 429; cristata, 439

Isle of Wight, a garden in the, 57, 70, 96, 140, 187, 252; notes from the, 79

Ivies—on Plane tree, 106, 127; tree, 273

Jadoo fibre, 53

Jones, Mrs., death of, 53

Judging gardens, 517

Kalosanthes culture, 365

Kangaroo Vine, 230

Kew Gardens, walks and talks in, 203

Kinnoull, the late Earl of, 117

Kitchen garden, the, 62, 104, 146, 190, 233, 273, 325, 374, 421, 515

Laburnums, vagaries in, 468

Lackey moth, the, 261

Laelias, prestans alba, Ashworth's var., 27; notes on, 366; purpurata malformed, 482

Laelio-Cattleyas—Rosalind, 54; Nysa superba, 118

Landscape gardening, book on, 170

Lapagerias, culture of, 228

Lawns, weeds on, 240

Leader, following the, 1

Leafy June, 501

Leeks for exhibition, 109

Lilies, Water, 214

Liliums—canadense, 101; top-dressing, 250

Lily of the Valley, Fortin variety, 348

Lines on reading a seed list, 271

Liverpool notes, 203

Llangedwyn, 100

Lobelias, increasing, 213

Lockinge Park, 201

Looking forward, 23

Looking round, 134, 178

Lucilia gratissima, 16, 32

Lunaria biennis, 224

Lupins for fodder, 242

Lupinus arboreus, 525

Lycaste Skinneri, 84, 366, 482

Magnolias leaves browned, 193; Soulangeana, 368; stellata, 448

Maianthemum Convallaria, 320

Manlewood, 434

Marigolds for exhibition, 247

Masdevallia tovarensis, 27

Medals of honour, 106

Melons—hints about, 62, 197, 238, 281, 420; in frames, 170; pests in Melon houses, 446; culture in troughs, 461

Microscopes, 377

Milne, Mr. W., death of, 179

Miltonia Roezli, 138

Mimicry in Nature, 181

Mimuluses, 33

Mint, lamb, root diseased, 423

Mission of flowers, the, 211

Monstera deliciosa, 388

Moraeas, 347

Moss, proliferous Feather, 196

Mosses, garden, harmful and harmless, 110, 227, 394

Mulching, 496

Mushrooms, outdoor cultivation of, 6; discoloured, 43; and Carrots, 84; preparing materials for beds, 127; spawn, 329; money in, 517

Mustard and Cress in punnets, 220

Myosotis dissitiflora, 339

Narcissi—after flowering, 193; Southern Star, 272; Ellen Willmott, 272

New Year, glad, the, 5

Night soil for Vines, 64

Nitrogen, 271

Nitrogen, 374

Odontoglossum crispum Luciani, 385; crispum "Starlight," 499; nebulosum, 516

Oleanders, scale on, 261

Oncidium—splendidum, 245; of the macranthum group, 337

Onions, diseased, 106; a note on, 181; the fly, 369

Orchard's, fertilisers for, 79

Orchids—Cattleya Prince of Wales, 11; Calanthes, 11; hybrid Cypripediums, 11; Dendrobium Wardianum, 11; Laelia prestans alba, Ashworth's var., 27; Masdevallia tovarensis, 27; Laelio-Cattleya Rosalind, 54; the Orchid house in January, 64; Zygocloax Veitchi, 68; Saccolabium giganteum, 69; Calanthes vestita and Veitchi, 93; Orchid sales, 98; Laelio-Cattleya Nysa superba, 118; potting, 118; pseudo-bulbs decayed, 118; Miltonia Roezli, 138; notes on Phalaenopsis, 157; sale at Marks & Tey, 157; deciduous Dendrobium, 197; Dendrobium Devonianum, 197; in flower, 226; Trichoglottis cochlearis, 245; Oncidium splendidum, 245; Hamburg Exhibition, 267; Dendrobium in beauty, 267; notes on Cymbidium, 267; Oncidium of the macranthum group, 337; at Aston Hall, 337; Lycaste Skinneri, 366; notes on Laelias, 366; notes on Aërides, 417; Cypripedium Lawrenceanum, 417; Manchester Orchid Society, 458, 499; Cypripedium villosum aureum, 482; Cologynne cristata Trentham variety, 482; Oncidium Kramerianum, 482; Lycaste Skinneri, 482; Orchids at Summerville, Dumfries, 482; Laelia purpurata malformed, 482; at the Temple Show, 499; at Mr. W. Bull's, 499; at Messrs. J. Veitch & Sons, 499; Epidendrums, 530

Ornithogalum diseased, 423

Osborne House, 563

Owen, Mr. R., death of, 410

Paonies, tree, 121; stock for tree, 217

Pains in Russia, 525

Pansies, diseased, 127; and Violets, 277

Peaches and Nectarines, 40, 81, 124, 168, 218, 273, 350, 398, 491, 539; in pots, 170; yellows in, 176; buds and flower falling, 240; excrescences on roots, 321; shoots diseased, 352; insects on branch, 376; trees casting their leaves, 446; causes of fruits falling, 468; trees against walls unhealthy, 493

Pears—the Pear slug, 9; Marie Benoist, 15; scale on trees, 170; bloom, 271; shoots and leaves blistered, 423; Pear-gall gnats, the, 486

Peas, Webb's Senator, 143; Carter's Daisy, 216; American Wonder, insects on, 422; early, 529

Pelargoniums, Zonal, diseased, 84; propagating, 213, 313; decorative, 446

Penrhyn, a call at, 188

Petunias, increasing, 214

Phalaenopsis, notes on, 157

Phytolipsis ribis, 64

Picturesque gardening, 423

Pietermaritzburg, round, 290

Pines, golden foliaged, 212; value of juice of, 438; notes on, 514

Pinnington, Mr. R., presentation to, 203

PLANTS AND FLOWERS CERTIFICATED BY THE ROYAL HORTICULTURAL SOCIETY—Amaryllis—Pera, 254; Brenda, 322; Chimbarozza, 322; Duke of York, 322; Ignacite, 322; The Czar, 322; Thueberg, 322; Topaz, 322. Anemita rotundifolia, 418. Anactochilus Sanderianus, 454. Anthurium Scherzerianum Giant Sanglant, 254. Auricula Fred Knighton, 361. Azalea—rustica fl.-pl. Freya, 454; rustica fl.-pl. Ribera, 454

Begonias—Diamond Jubilee, 454; Queen of Queens, 454. Bulbophyllum Ericssonii Krangleri, 199

Caladiums—Lady Stafford Northcote, 454; Mrs. McLeod, 454. Calochortus Gunnisoni, 537. Cauna Com'e de Bouchard, 254. Carnations—Artemus, 254; Barras, 537; Cecilia, 537; Helmsman, 537. Cattleyas—Loddigesii superba, 29; Triana eximium, 118; Triana Imperator, 113; Mossia Empress Queen, 454; Schilleriana Hardy's var., 454; Mendell Madonna, 454; Mossia In Memoriam Richard Curnow, 537; Mossia Empress of India, 537. Cedrus atlantica aurea, 537. Celmisia Monroii, 537. Chionodoxa Lucilia alba, 199. Clematises—Marcel Moser, 455; Duchess of Albany, 455. Cologynne Dayana, The Dell var., 455. Cotoneaster horizontalis, 199. Croton Her Majesty, 455. Cyclamens—papiio, 29; grandiflora alba, 199. Cypripedium eburneum, 199. Cypripediums—Lebaudy-anum, 29; Lilian Greenwood, 29; hirsuto-Sallieri, 199; belatulo-vexillarium, 418; Chapmani magnificum, 418, 455; concen-bellatulum, 455

Davallia hirta, 255. Delphiniums—Clara Stubbs, 537; Sir John Forrest, 537. Dendrobium Ashworthi intertextum, 199. Disporum Leschenaultianum variegatum, 254. Doryopteris nobilis, Duvallii, 537

Erythroniums—Nuttallianum, 254; revolutum, 322. Escalonia langleyensis, 537

Ficus radicans variegata, 455. Fuchsia Addington, 322

Irises—Bakeriana, 118; Lupina, 455; Germanica maxima, 537

Laelias—Lucy Ingram, 30; purpurata fastuosa, 455. Laelio-Cattleyas—Violetta, 113; Digbyana-Trianae, 322; Hypopolyta, Dulcote variety, 418; Lady Wigan, 455; tyntes, fieldense, 455; Our Queen, 537; Empress of India, 537. Lilac Senator Holland, 418. Lithospermum tinctorum, 361. Lycaste Skinneri pulcherrima, 199

Masdevallia Pourbaixi, 199. Mormodes labium luteum, 50. Muscari conicum, 322

Narcissi—Ellen Willmott, 254; Lettice Harmer, 254; Southern Star, 255; Beacon, 322; M. de Graaff, 322; Snowdrop, 322

Odontoglossums—crispum Ami Charles, 199; crispum Kegeliani, 199; crispum Luciani, 255; Ruckerianum ocellatum, 255; Andersonianum, Danehurst variety, 322; Wilckeanum Queen Empress, 322; crispum heliotropium, 361;

PLANTS CERTIFICATED—
continued.

- Andersonianum Bogaerdianum, 418; *Pescatorei* Imperiale, 455; *excellens* var., 455; *crispum* Queen Victoria, 455; *sceptrum aureum*, 455; *excellens* Thompsoni, 455; *crispum* Annie, 455; *crispum* Peetersi, 455; *crispum* Starlight, 455; *crispum* Crawshayanum, 537; *Ornithogalum grandiflorum*, 322.
- Petunia* Mrs. Fred Sander, 455. *Phalaenopsis* Hebe, 113. *Phyllocacti*—*Adonis*, 455; *Syrens*, 455. *Pink Albino*, 537. *Polyantus* Woodside Gem, 255. *Primula* Trailli, 361. *Pyrethrum* Wilson Barrett, 455.
- Rhododendrons*—*superbissimum*, 361; *Pink Pearl*, 418; *Madame Moser*, fl.-pl., 455. *Roses*—*Antoine Rivoire*, 255; *macrophylla*, 537.
- Solanum tuberosum* variegatum, 322. *Streptocarpus achimenesifera*, 418.
- Trollius napellifolius*, 418. *Tropeolus*—*Phoebe*, 322; *Mrs. Sanderson*, 361. *Tulipa Kaufmanniana*, 255.
- Vanda* Agnes Joachim, 537. *Violet* Amiral Avellan, 113. *Zygopetalum Perrenoudi* superbum, 322.
- Plant border, our hardy, 131, 152, 185, 224, 308, 334.
- Planthouses, 18, 62, 104, 147, 191, 239, 281, 326, 398, 491; decorative, 196.
- Plants, do they think? 255; treatment of seedling, 356; constituents of, 431; in house decoration, 435; raising spring flowering, 485; eccentricities of, 526; influence of microbic life in the nutrition of, 526; greenhouse, plunging, 541.
- Platylobium formosum*, 277.
- Pleasure grounds, natural beauty in, 320, 392.
- Plonging in a greenhouse, 410.
- Plums, growths and blossom blighted, 305.
- Poinsettias*, 8, 497.
- Polyanthus*, border, 339.
- Pontederia crassipes*, 364.
- Portraits—Mr. C. Harman Payne, 2; Mons. E. Fierens, 31; Mons. O. de Meulenaere, 31; Mr. W. Cunthbertson, 34; Mr. David Thomson, 204; Dr. Robert Hogg, 232.
- Potatoes—for exhibition, 53; the discolouration of, 76, 91; cooking, 115, 142, 207; diseased, 126; forcing, 163; formalin for the scab, 270; pests in America, 270; quality of, 278; chemical manure for, 283.
- Pots, flower, clean and dirty, 352.
- Precept and practice, 24, 48, 88, 132, 177, 227, 294, 369, 386, 423, 475, 500.
- Prescot House, 298.
- Primulas, and *Cyclamens* at Reading, 160; *calycina*, 359; early Chinese, 520; *P. Trailli*, 523.
- Propagating, March, 213.
- Pruning, winter, 14, 56; pruning maiden trees in pots, 85, 148; tree, 151; simplicities of, 173.
- Prunus*, *nana*, 53; *Davidiana*, 137, 434; *triloba*, 322, 352; *pseudo-cerasus*, 388.
- Pyrus floribunda*, 363; *specabilis*, 388.
- Queen's reign, the, commemorating, 45.
- Rains, the, 528.
- Radishes at Chiswick, 359.
- Ramondia pyrenaica*, 187.
- Rangemore, Carnations at, 121, 166.
- Ranunculus grandifolius*, 465.
- Red spider on Gooseberry foliage, 418, 463, 477.
- Redwoods, the height of, 180.
- Resting tour, a—Bridge of Allan, 34; Stirling, 34; Rothesay, 35; Drumlanrig, 204.
- Rhododendrons*—*grande*, 9; *præcox*, 181; at Kew, 252; notes on, 388; *Kewense*, 489.
- Rhubarb*, 375; forced, 9.
- Ribes aureum*, 353.
- Rival queens, 160.
- Riviera, the, notes from, 69.
- Rochford House, 15.
- Rockeries, forming, 92.
- Roses*—*Maréchal Niel*, 20; "the Rosarian's Year Book for 1897," 37; the hybridisation of *Roses*, 51; *Polyantha* and *China*, 91; *Enchantress*, 119; pruning *Tea*, 171; *Mrs. John Laing* and *Mrs. R. G. Sharman Crawford*, 188, 214; *A. K. Williams*, 214; *Hybrid Tea*, 214; show fixtures for 1897, 275, 297, 341, 360, 390, 416, 434, 456, 479, 524; budding in February, 275; seasonable notes, 297; feeding, 370; a *Rose* day proposal, 360; *Roses* under glass, 360; the National *Rose* Society's shows, 390; the malevolent weevil, 416; progress with *Maréchal Niel*, 416; comments and impressions—manures, 436, 479, 510; deformed, 493; new, 510; comments and impressions—medals and prizes, 524.
- Rubus*, coloured stemmed, 51.
- Ruscus aculeatus*, 278.
- Saccolabium giganteum*, 69.
- Salvia gesneriflora*, 344.
- Sanguinaria canadensis grandiflora*, 390.
- Sarmienta repens*, 395.
- Saxifragas*—*apiculata*, 7; alzoom on a roof, 92; *Burseriana*, 215; *Burseriana major*, 320.
- Schizocodon soldanelloides*, 323, 339, 439.
- Schools, flowers for, 310; gardens, 334, 435, 511.
- Scopolia Fladrichiana*, 289.
- Seakale, forcing, 135; culture, 405.
- Sechium edule*, 310.
- Seeds, proportion of, to length of row, 241; depth and distance of sowing, 241; foreign, 376.
- Sempervivum arachnoidem*, 92.
- Senecio grandifolius*, 10; *macrogllossus*, 220.
- Sharpe, Mr. C., death of, 200.
- Shelters for early bulbs, 7.
- Shows—*Grassendale*, 251; *Edgbaston*, 258; *Torquay*, 278; *Royal Botanic*, 279; *Shrewsbury*, 316; *Brighton*, 323; *Auricula* and *Primula*, 323; *Berlin*, 381; *Hamburg*, 382; *Northern Auricula*, 393; *Temple*, 449; *Northern Tulip*, 487; *Butley Tulip*, 488; *Tamworth Viola* and *Pansy*, 489; *Manchester*, 512.
- Shows, disqualification at, 28; record reign, 308.
- Shropshire Horticultural Society, 116.
- Shrubs—planting, 241; spring blooming, 250.
- Slugs and snails infesting ground, 221.
- Snow, the, 74.
- Soda*, 366, 431.
- Soils, chalky, trees and shrubs for, 37; of pasture land, 126; insects in, 126; the origin of, 186; the formation of, 237; the composition of, 247; mechanical analysis of, 247; soil moisture, conservation of, 496.
- Solandra grandiflora*, 123.
- Solanum macrocarpum*, 72.
- Soldanellas*, a note on, 215.
- Sophronis grandiflora*, 318.
- Spinach*, 19.
- Spiræas*, with dead flower stems, 282; falling, 328; *Thunbergi*, 333.
- Spring in London, 296, 341.
- Spring scenes, 268.
- Staphylea colchica*, 183.
- Sternbergia Fischeriana*, 466.
- Stocks, Paradise, for Western America, 106; *Brompton*, 446.
- Storm, the effects of a, 532.
- Strawberries—*Everlasting*, the, 21; culture of, 182; attention to, 218; chemical manure for, 376; *Royal Sovereign*, 408; at *Knowsley*, 438; leaf fungus, 468; for the Jubilee, 480; plants, non-productive, 503, 528.
- Streets, flowers of the, 335.
- Stylophorum diphyllum*, 475.
- Styrax obassia*, 506.
- Sulphur, remedies with, 434.
- Summerville (*Dumfries*), Orchids at, 482.
- Swainsonias, 481.
- Swamp, dismal, a trip to, 16.
- Swamore Park, 532.
- Sweet Peas, and tame pigeons, 352; note on, 426, 515.
- Sweet Williams, 135.
- Temple Show, 449.
- The glad new year, 5.
- Thomson, Mr. D., retirement of, 94; presentation to, 179; portrait of, 504.
- Thuja occidentalis falcata*, 368.
- Thuidium Tamariscinum*, 196.
- Tomatoes—in troughs, 20; raising early, 49; manure for, 93; hard water for, 106; and *Cucumber* troubles, 129, 174, 221, 264; worm destroying plants, 149; for out and indoors, 171; diseased, 231; yellow spots and blotches on leaves, 282; leaves mottled, 305; variegated patches on foliage, 305; leaf-ribs rusted, 328; in *Cheshire*, 339; seedlings withering, 352; in pots, 409, 466; early in the Isle of Wight, 410; constituents of and manures for, 425; flagging disease, 460; open air, 471; flowers and young fruit diseased, 493; flowers dropping, 516; *Hepper's Goliath*, 505.
- Trees, and shrubs for chalky soils, 37; planting—the duty of one generation to another, 67; how they are built, 111; flowering trees and shrubs, 138, 153, 182, 211; pruning trees, 151; *Deutzia candidissima* fl.-pl., 153; *Staphylea colchica*, 183; cutting down trees on commons, 180; the influence of wind on, 250; productive and unproductive, bud and graft influence, 495.
- Trichoglottis cochlearis*, 245.

VEITCH'S GENUINE SEEDS.

Veitch's Extra Early Cauliflower.

First-class Certificate Royal Horticultural Society. Of dwarf compact habit. Comes into use earlier than any other variety. Highly recommended for forcing.

Per Packet, 1/6 and 2/6.

Veitch's Earliest of All Cabbage.

An exceedingly early variety, especially adapted for spring sowing, and coming into use quicker than any other sort.

Per Packet, 1/-.

Veitch's New Dwarf Bean.

EARLY FAVOURITE.

Award of Merit, R.H.S.

A most desirable early variety for forcing or general use, producing an immense crop of long pods, very superior in quality.

Per Packet, 1/6.

SEED CATALOGUE for 1897 has now been posted to all their Customers. Anyone not having received the same, a duplicate copy will be forwarded, post free on application.

JAMES VEITCH & SONS,

ROYAL EXOTIC NURSERY,

CHELSEA, LONDON, S.W.

MR. ROBERT SYDENHAM'S SWEET PEAS

Are the best and cheapest ever offered. Collection No. 1: Ten really good varieties, 50 seeds of each, 1s. 3d.; Collection No. 2: Ten very best varieties, 50 seeds of each, 1s. 6d.; or the two Collections, 2s. 6d., post free. Collection No. 3: Ten newest novel varieties, 30 seeds of each, 3s.; or the three Collections, post free for 5s., with a packet of "CUPID," the new dwarf white, free of charge. Full particulars, with lovely Coloured plate, post free on application.

TENBY STREET NORTH, BIRMINGHAM.

o Nurserymen, Builders, Local Boards, Vestries, and others who intend planting Trees and Shrubs this Season

ROBERT NEAL,

the Nurseries, Trinity Road, WANDSWORTH, S.W.,

Begs to offer an extensive stock of FOREST and ORNAMENTAL TREES and SHRUBS, ROSES, GRAPE VINES, FRUIT TREES, CLIMBING PLANTS, &c., which, being grown in the neighbourhood of London, are specially suitable for town planting. Also a large stock of SWEET PEAS and RHUBARB for forcing. Sample and price of each sent by post if desired.

DESCRIPTIVE CATALOGUE FREE.

ORCHIDS.

CLEAN HEALTHY PLANTS AT LOW PRICES.

Always worth a visit of inspection. Kindly send for Catalogue.

JAMES CYPHER,

Exotic Nurseries, CHELTENHAM.

20 ACRES of FRUIT TREES

In all the best sorts and forms for the Villa Garden or the Orchard. Free from blight and disease, clean, healthy stems, and branches carefully pruned in good form. Roots a mass of fibre. Sizes from maidens to trees six to eight years old of many kinds, and all TRUE TO NAME.

NEW CATALOGUE, with descriptions and Prices, Post Free.

CLIBRAN & SON,

MANCHESTER, Bangor, Llandudno Junction, and Oldfield Nursery, ALTRINCHAM.

Barter's TESTED SEEDS.

The Best Vegetables
and Fruit for Early Use.

SOW AT ONCE

CARTERS' FORCING PEA.

A New Winter and Spring Marrow, valuable for under-glass culture. Height, one foot.

In Sealed Packets, price 2s. 6d. per Pint, post free.

CARTERS' STRINGLESS FRENCH BEAN.

An extra early dwarf green-podded variety.

Mr. O. J. TALLACK says:—"It is the quickest to come into use I have ever grown"

In Sealed Packets, price 2s. 6d. per Pint, 4s. per Quart, post free.

CARTERS' LONG FORCING CARROT.

Quite a new type, retaining its colour under forcing culture. The Garden says:—"It grows as quickly as the earliest, and is a decided acquisition."

In Sealed Packets, price 1s. 6d. each, post free.

CARTERS' EARLIEST of ALL CUCUMBER

In a careful trial for earliness, this fine variety was proved the quickest to finish its fruits by nine days.

In Sealed Packets, price 2s. 6d. each, post free.

CARTERS' HARBINGER LETTUCE.

Valuable for under-glass culture, where early salading material is required.

In Sealed Packets, price 1s. 6d. each, post free.

CARTERS' BLENHEIM ORANGE MELON.

This grand scarlet-fleshed Melon is one of the quickest to ripen its fruit, and is very largely grown for early summer use.

In Sealed Packets, price 2s. 6d. each, post free.

CARTERS' DELICATESSE RADISH.

A greatly improved type of the French Breakfast Radish, introduced by us many years ago. Very suitable for forcing.

In Sealed Packets, price 8d. per Ounce, 3s. 6d. per Pint, post free.

CARTERS' DUKE OF YORK TOMATO.

This grand variety is now grown in the best establishments in preference to all others. Its record upon the exhibition table is also unapproached by any other Tomato.

In Sealed Packets, price 2s. 6d. and 3s. 6d. per Packet, post free.

Illustrated CATALOGUE, Gratis and Post Free.

Journal of Horticulture.

THURSDAY, JANUARY 7, 1897.

FOLLOWING THE LEADER.

SOOTHING and satisfying. This is the opinion of one who would fain follow the leader—the "New Year's Greeting" on page 623—with the expression of a few thoughts and many reciprocal wishes to the veteran writer whose message of peace flowed so smoothly and so sympathetically from the mellow pen. The feeling will, I think, be unanimous that the "greeting," though but briefly touching upon the higher things of horticulture, and skilfully interweaving the still higher things of life, is both soothing and satisfying. Doubtless there are many who feel the need of a lubricant, without which the wheels of life, even though trundling through the sphere of a gardener's vocation, are apt to jar a little at times; and at this season, when we are about to start upon another round, it is especially helpful.

A little thoughtful reading of the "New Year's Greeting" will, too, reveal how suggestive it is of many things but lightly touched upon, with their deep, almost pathetic meaning, and I cannot but feel how happy is the expression which admits us as gardeners, far removed maybe in more ways than one, within that boundary which defines the *Journal of Horticulture* as "Our" Journal. If there were any further need to strengthen the feeling it is, I think, to be found in the contemporaneous address, "To our Readers;" and, again, this might still further be added to by noting the space which has been lately set apart and bears the heading of "The Young Gardeners' Domain." This, I believe, marks an era in horticultural literature, although some bright papers went straight from the bothy into the pages of an interesting little monthly several years ago.

That our boys will appreciate the privilege, with all the advantages it may and should confer upon them and their object in life, it is only reasonable to expect. If there is one lad who is diffident of entering that domain, because there is, or he thinks there is, brighter workmen with the pen than he, then I would say to him, Try; say what you think upon some subject of general interest, and say it in a natural, easy manner, without any pretensions to graphical

display, for such is not expected of you, nor is it desirable; fit your ideas into the homely garments of our mother tongue, and we—elders—shall admire them more than in the grandest dress you might strain to engarb them.

One must in these desultory thoughts shunt on to side tracks—feeders to the main line on which the *Journal of Horticulture* has run so ably and so long. It is now approaching a stage of some importance in its career, scarcely of secondary importance to us as gardeners than in this newborn year with its bright anticipations of the sixtieth celebration of Her Majesty's glorious reign to us as loyal subjects. When the tale of this year is told the *Journal of Horticulture* will have entered upon its jubilee—a golden wedding of literature with horticulture; and whether as readers or as writers, or both combined, we cannot but feel the hope which it is not premature to now express, that we may then bid "Hail to the Chief" whose banner bears the motto "For Gardening and for Gardeners."

To look back upon the vast amount of horticultural literature as exemplified in those goodly arrayed volumes of the *Journal of Horticulture* one might momentarily suppose that all that could be said for or about gardening has been said, but the slightest reflection shows the absurdity of such a thought. I once heard it remarked that "The gardener is a man who is never satisfied; first he wants more glass, then he wants more plants, then again he wants more glass and so *ad infinitum*." In this direction the limit might probably be found, although there are a few men I know who, if the whole garden were enroofed with glass, would want a little cool Orchid house or something of that ilk fixed on the wrong (or right) side of the garden wall. However, be that as it may, there are no limits so far as one can see to learning or to the teaching of the Journal, and the planting within its perennial borders must still go on for the advancement of gardening and gardeners present and to come.

"This year will be a great year in London, and you must go," says a friend. He spoke in the imperative mood, which must give place to the conditional; but, seriously, we have good grounds for hoping and believing that it will be a great year in London and beyond, stretching far away over that Empire on which the sun never sets. The relevancy of it to these thoughts consists of what has been advanced in these pages whereby horticulture may worthily join in celebrating Her Majesty's long reign. Far be it from me to suppose that any thoughts of mine would materially aid the matter any more than that my presence in London as a loyal unit would affect the vast sum who will delight to honour our revered Sovereign.

I had thought there were good reasons why a Gardeners' Club should be considered upon its merits, but "good reasons must of force give place to better." Moreover, those thoughts were, I fear, rather prompted by selfish considerations than regarded in that strong light with which a broad subject should be viewed. Anyway, some sound practical logic has been advanced *per contra* which had not entered into my somewhat hasty and hazy calculation. Whilst endeavouring to avoid entering upon debateable ground, or, indeed, fling any challenge into it, permission is asked to show that this passing dream is not entirely shattered by the shafts of better marksmen. Undoubtedly Mr. Wood's great scheme is one born of no hasty conclusions. It is, indeed, "too great for haste, too high for rivalry," therefore too far removed, not from its object, but from humbler propositions to provoke invidious comparison.

Man, as we know, is not only a gregarious animal, but clings to that order of his species to which he belongs, hence a gardener in London town may feel a little of what I have felt on few and far between visits—viz., isolated in that great agglomeration of humanity. In this case it is not a question of board, lodging, and entertainment, nor need that be ignored; but it is a question of the enjoyment of those privileges which communion of fellowship entails; and a gardener's club might well afford this and more also under the protective agency of sound rules of membership, of which parallel instances are afforded in other phases of life. I feel that there is a great deal more which might be advanced in its favour; I know there is probably as much which could be said against

it; but still venture to think that the latter cannot entirely neutralise an idea which, however crude, is capable of being polished into something more pleasing, something more tangible.

"D., Deal's," kindly greeting and the address "To Our Readers" are the sparks which have fired this train of thoughts (more smoke than fire perhaps), yet ere extinguished by the editorial foot one would fain fan the dead past in order to gain a little light for the future. The weather record of 1896 is to some extent remarkable, but not sufficiently so, I think, to render the year conspicuous in history, for its character, whilst not being very good, can hardly be termed very bad. To sum up, it has been what may be called trying—trying to gardeners, finding out their weak points, and surely trying to those who, as weather prophets, venture, or rather attempt, to predict it; and how often are they tried and found wanting. Some remarkable instances could be given to illustrate the utter futility of endeavouring to bring this apparently ungovernable factor within the limits of human prescience—that is to any appreciable extent. What better data could be afforded than the waning, weeping days of the dear defunct 1896? True, we are not yet out of the wood, and may be as near to Arctic severity as Nansen was to the Pole, but to-day the bairns have brought in blooms of the Coltsfoot, which were revealed to them by the delicate Heliotrope perfume, and the precocious Primrose has furnished our local paper with the proverbial letter on the mildness of the season. This, too, after much shaking of old heads over the abnormal crop of berries, and dire predictions measured by the extent of the crop.

There are so many texts furnished directly or indirectly by the New Year's number that one might go on and on, only there would not be room in the present one. How easy it is to follow a good leader; long may he be spared to introduce other New Years as ably as he introduced this year of glorious hope, hopefully pointing the way, gently vibrating the chords and pen of—AULD LANG SYNE.

MR. C. HARMAN PAYNE.

WE have pleasure in giving the portrait of this diligent Chrysanthemumist (fig. 2) as caught in his travelling cap by the kodac at Charing Cross just when he had taken an insurance ticket for the Continent. He has been the editor of all the N.C.S. catalogues since 1886, and was, we believe, appointed Foreign Secretary of the Society, on the proposition of Mr. Holmes, in 1888. As is well known by most of his personal friends he is a member of most if not all the French Chrysanthemum societies, also of the French Horticultural Society of London, and speaks French like a native. Besides contributing to the *Journal of Horticulture* and other English gardening as well as American papers, the ready pen of "P." has also assisted American, Belgian and French authors in compiling books on the Chrysanthemum, and it is said he will never be happy till he can pass an examination in Japanese.

If we remember rightly Mr. C. H. P. was awarded silver-gilt medals at the Lyons and Grenoble Chrysanthemum shows for a collection of coloured engravings pertaining to the golden flower, and he has been the recipient of many other honours which we cannot remember; but a few occur. M. Anatole Cordonnier dedicated his book "Le Chrysanthème à la Grande Fleur," to "C. Harman Payne." And in June last his portrait was published in the "Nord Horticole," with several pages of biographical notice from a French point of view, as an accomplished amateur. Mr. Payne edited the Jubilee edition of the N.C.S. official catalogue, and was awarded a Jubilee silver medal for his services. That was good, but something better followed, for he was recently appointed *Chevalier de l'Ordre de la Mérité Agricole* by the French Government for his literary services, as witness the distinguished decoration (fig. 1).

Then in December, just gone, our friend was awarded a gold Jubilee medal by the General Committee of the N.C.S., and an illuminated

address expressing "the esteem of the members and the high value placed upon his services as Hon. Foreign Corresponding Secretary, together with the great respect and appreciation of the members of the N.C.S.

FIG. 1.—MR. C. H. PAYNE'S L'ORDRE DE LA MERITE AGRICOLE.

for the many valuable and arduous duties performed by him in the interests of the Society during the past years." He has evidently gone through a great deal, and we can imagine the writer of the well-deserved and eulogistic tribute shedding a few tears of gratitude over it at Anderton's.

Mr. Payne has during his office of Foreign Secretary been twice on the Continent in the interests of the N.C.S., and we are told by an outsider that he had the honour of doing this at his own expense. It is a Payneful list altogether, but the victim is wiry, and our hope is that he will survive the inflictions for many years, for he combines industry with ability, and is one of the most active and useful men in the Chrysanthemum world.

A TOUR ABROAD BY A HAPPY TRIO.

THE Editor of the *Journal of Horticulture*, knowing the deep interest that is taken by many of its readers in all that concerns the Chrysanthemum, has invited me to send a few notes relating to the recent wanderings of the deputation sent by the National Chrysanthemum Society to the continental Chrysanthemum shows.

The fame of the N.C.S. is of course largely due to the magnificent exhibitions that the Society has annually held, to the reports of the Society's proceedings as published in the horticultural press, to the publication of its official catalogue, which has done very much to popularise the Society both in America and on the Continent, but very little up to the present regarding personal contact between its members and the growers of the popular flower abroad. In 1889, about twelve months after my appointment as Foreign Secretary, the centenary of the introduction of the Chrysanthemum into Europe was celebrated by several societies in France and Belgium, and it will be remembered that some of the members of the N.C.S. were invited to act as members of the Jury at the Ghent Chrysanthemum Show held that year, and that they went as an official deputation.

Seven years have passed since then, and speaking purely from a Chrysanthemum standpoint, there has until the past season been no means of further extending our acquaintance with the foreign growers, except by correspondence or of making fresh friends. And what perhaps is of importance, we have been unable to form any just idea of the progress in cultivation that has recently been made over there, all our information on that score being second-hand. It was, therefore, with some degree of satisfaction that I received a few months ago a formal invitation to be present at the November Show of the Royal Agricultural and Botanical Society of Ghent, and to know that several of my friends and colleagues of the N.C.S. were to be similarly honoured. It was a still further gratification to find that the Paris Chrysanthemum show would also be open to us on the same terms a few days later; and

my previous experience being limited to Belgium, it was a fortunate coincidence that such of us as went would be able to gain a personal experience of how they grow and show Chrysanthemums in the two countries.

Although seven or eight of our fellow members were invited, the actual number able to go when the time arrived was only three—Mr. H. J. Jones of Lewisham, Mr. Thomas Bevan (the Chairman of the Floral Committee), and myself. Besides visiting the two important shows of Ghent and Paris we decided to take in any others that could conveniently be done; but we found that in our short stay we had undertaken almost enough to more than fill up the time.

Our excellent friend Mr. Bevan, ambitious that the N.C.S. should shine abroad by some of the productions of its members, collected good blooms to stage at the Ghent show in the name of the National Chrysanthemum Society. It was entirely his own idea, and so well carried out that he deserves the best thanks of the Society. Messrs. Cannell and Jones had also contributions, and our luggage assumed alarming proportions. I need not recount our trouble and anxiety in getting our precious consignment to Dover, nor of the difficulty in transferring the boxes to the Ostend boat; but at length we got them on board. The flowers were carried down into the cabin, and, of course, placed close against the stove. Not being stove plants they had to be "re-arranged."

At this season of the year travellers from England to Belgium are rather few by the night service, and we had the deck entirely to ourselves. The night was black and overcast, the wind was keen, and after promenading the deck for a time, and the spray having an unpleasant way of dashing over the bows for a long distance, we retired to a snug little corner and began to relate experiences.

Mr. Jones had just returned from Belfast and Sheffield, and I have always held that travelling is good for many reasons; it enlarges the mind, it increases knowledge, and improves the conversational powers. It is really wonderful what a charm there is in the stories of a traveller, and our friend Jones certainly did his best to while away the monotony of crossing the Channel on that bleak dark night by recounting all the curious little anecdotes and stories he had gathered together up to that time during the Chrysanthemum season. At any rate, he had a sympathetic and appreciative audience, if only a small one, and we all felt somewhat disappointed when the lights of Ostend appeared in sight.—C. HARMAN PAYNE.

(To be continued.)

CONFUSION IN NAMING CHRYSANTHEMUMS—G. J. WARREN v. YELLOW MADAME CARNOT.

UNDER the above heading "Interested" (page 605) writes *re* G. J. Warren, and I am not surprised, for on November 18th, 1896, I submitted G. J. Warren, yellow sport from Madame Carnot, at the N.C.S. Committee, the entire plant. On November 24th the same was exhibited at the R.H.S. On November 25th Mr. Jones ordered plants of this, Mr.

FIG. 2.—MR. C. HARMAN PAYNE.

Lees having also ordered plants. On December 1st Mr. Jones submitted blooms to the N.C.S. Committee, under the name of Mrs. F. A. Bevan. I was also asked if I would rename my G. J. Warren Mrs. F. A. Bevan.

What! rename it after I had bound myself by agreement, and distributed circulars, and advertised it as G. J. Warren. What next?

Now, what does "Interested" see? Wells' specialist, with G. J. Warren, yellow sport from Madame Carnot. Correct. "Gardeners' Magazine," last issue, has Mrs. F. A. Bevan, yellow Madame Carnot. Why did the N.C.S. Committee recognise this? or why did it ignore G. J. Warren? Mr. Davis has Mrs. F. A. Bevan, flesh pink, catalogued; while Mr. Jones has yellow Carnot without a name. Is it not worth a name? Does he ignore the name he gave it? I do not wonder at "Interested" being confused.—W. WELLS.

THE yellow sport from Madame Carnot that was staged at the N.C.S. meeting under the name of Mrs. F. A. Bevan was exhibited by myself. I at first thought that my sport was a darker yellow than the one exhibited by Mr. W. Wells under the name of G. J. Warren, and intended to give it a distinct name, but later, on carefully considering the difference in the age of the flowers exhibited, I thought it better to simply call it Yellow Madame Carnot until it has been grown side by side with G. J. Warren, when if it proves the same shade of colour it can have the same name; if it is a different shade it can retain the name of Yellow Madame Carnot, so there is really only one Mrs. F. A. Bevan offered in any catalogue.—H. J. JONES.

THIS charming Japanese sported last year from Madame Carnot in the gardens at Balcombe Place, Sussex, where it cannot be said to have received the highest culture. Being a sport, naturally the growth and formation of blooms are identical with its parent. The colour is canary yellow on the surface, with lemon yellow reverse. Mr. Wells, I hear, is the fortunate possessor of this novelty.—E.

THE N.C.S. JUDGES.

"FAIR PLAY," whose very uncomplimentary inuendoes (page 606) do not convey a very fair mind, seems in his strictures on the N.C.S. judging by members of the Committee to overlook the fact that this body, I admit too large and unwieldy, comprises thirty-six members, in addition to six others as officers, and of necessity includes many of the best Chrysanthemum growers, exhibitors, and judges in the kingdom. If all these are to be excluded from the post of judge at the N.C.S. shows, then will many of the best men be excluded from acting as such. By parity of such reasoning as "Fair Play" indulges in, every member of the N.C.S. Committee should be excluded from judging at shows of affiliated societies also—that is, therefore, to reduce his complaint *ad absurdum*.

To desire that trade growers should not judge in classes in which any blooms they may have special interest in are shown is right, but it must not be forgotten, for instance, that in the shows of the National Rose, Dahlia, and Carnation Societies, not only do traders in these various flowers constantly judge the amateurs' classes, and *vice versa*, but also that judging by members of the respective Committees is constantly practised. The singling out of the N.C.S. by "Fair Play" rather evidences some little spite—at least, it looks so.

To judge the decisions of the judges, even severely, is the privilege of everyone, and it is a very proper privilege too; but when such criticism degenerates into what appears like spite and vindictiveness, then matters go too far. If the appointed judges are ignorant or incapable, say so; but attributing corrupt motives is argument very apt to recoil on the accuser.—A MEMBER OF THE N.C.S.

[We agree with our correspondent that when a critic is so far animated by personal spite as to attribute corrupt motives to individuals who act contrary to his desire that he will be the chief sufferer in reputation in the long run. We know of no reason why "Fair Play's" criticism should be other than genuine. We presume he objects on principle to the unpleasant duty being imposed on judges of granting awards to exhibits containing products in which they may be personally interested, and we also presume that if he were asked to judge by his fellow members of the N.C.S. that he would decline the honour. It is quite true that other floral societies do what is stated, but we do not think "Fair Play" is a member of them, and therefore only interested in the N.C.S.]

PROPAGATING CHRYSANTHEMUMS.

VARIOUS are the methods adopted by cultivators in rooting cuttings of Chrysanthemums. The propagating season is now in full swing, and it is interesting to note the various ways which enthusiastic growers employ in the treatment of the cuttings. Some pin their faith entirely on a close system of propagation, inserting the cuttings singly in small pots, which are stood under frames or hand-lights in a greenhouse or vinery. The same system also answers when several cuttings are inserted round the edges of pots. It is not absolutely essential that the frames or hand-lights be entirely airtight when closed down, but only so that the atmosphere is still and moist, which will prevent rapid evaporation from the foliage. The pots must stand on some moisture-holding base, by which a slight but constant humidity is maintained. This will be enough to retain the soil moisture without recourse to frequent watering or syringing. An important point to remember and practise in the management of cuttings on this principle is to wipe dry the inside of the glass every morning.

The signs which indicate rooting has commenced also denote that the admission of air must be increased gradually until the lights or covers of the frames or hand-lights can remain open or off altogether. Bottom heat is not necessary except when it is required to hasten the rooting.

Even then the heat must be mild and steady, or the cuttings may be weakened by forcing. When heat is applied to aid rooting success is best insured by keeping the tops cool.

The gradual exposure to plenty of air stiffens the foliage and modifies growth, but transfer the plants to shelves near the glass in a cool airy structure as soon as it is possible to do so without distressing them.

The system of propagation above alluded to is the safest and best for readily rooting cuttings of exhibition varieties, also for insuring against possible loss of choice new or scarce sorts.

Sturdy sucker cuttings are the best when obtainable. Of some varieties stem cuttings can only be employed because of the scarcity of the more desirable material which springs from below the soil level. The most inferior stem cuttings are those which are furnished with flower buds. Avoid such if better can be secured. I may be wrong, but in my opinion the heel of older growth attached to stem cuttings does not prove of much advantage in rooting; therefore I invariably trim the cuttings to the younger tissue just above, finding they root quicker. It is also well to avoid cuttings with woody stems, none the less so if they have roots attached. Cuttings having more succulent stems furnished with active rootlets at their base are sometimes to be met with. These, if not too long, ought not to be discarded. Sturdy examples soon take root, growing quite vigorously. Place them singly in 2½ or 3-inch pots by the usual method of potting rooted cuttings. It is probable they will not flag at all, and do not need the protection of frame or hand-lights. The pots, however, should occupy a moderately cool, moist position. As soon as established move the plants closer to the glass.

Another method of rooting cuttings is frequently practised. It is, apparently, entirely opposed to the close system of propagation. This consists of simply placing the pots of cuttings on a moist shelf or stage in a low and but slightly heated structure. If a stage covered with moist fine ashes, gravel, or spar is available the conditions suitable are at once secured. Drying the atmosphere by heat or draughts will prove disadvantageous. The cuttings root slowly but surely. Much depends on the weather and the intelligent management adopted. The soil must be thoroughly moist when the cuttings are inserted; afterwards a daily skiff with the syringe, more or less according to circumstances, provides the humidity favourable to rooting.

Flagging of the leaves is not necessarily fatal to cuttings, but it is best to avoid it if possible, especially during the early part of the time after insertion. This is the most trying period, during which the fresher the cuttings can be kept the better. The base shortly develops the callus or ring of tissue from which roots are ultimately emitted. This tissue once formed the cuttings are generally safe. Roots issue sooner or later according to the conditions of soil temperature and moisture. Maintain the atmosphere steady and humid too.

The compost for cuttings needs to be light and sandy. Equal parts of loam broken up finely, leaf soil passed through a quarter-inch sieve, and a liberal addition of sand. Mix thoroughly, employing it moist when filling the pots, which should be clean and dry: 3-inch or 3½-inch pots are the best for a number of cuttings to be inserted round the edge. For single cuttings 2½-inch pots are the most suitable. In preparing them for use place a little loose drainage in the bottom of each, and protect with damp moss or fibry material from the loam. Press, or rather shake the soil firmly down in the pots, surfacing with a layer of clean white sand, which may be dry. If so, a number of grains will follow the cutting stick, and thus form a sandy base for the cutting to rest upon. It will largely prevent damp and decay. It assists the formation of roots. The layer of sand, too, indicates by its damp or dry condition the proximate state of the soil below. When inserting cuttings it is important that the base of each should touch the bottom of the cavity, and not be hung half way therein. In forming, therefore, the holes for their reception, note the length each separate cutting requires to be buried, so as not to place it too shallow or too deeply in the soil.

Take special care in labelling correctly and distinctly each lot of cuttings as inserted. Always follow one simple method in marking those round the edges of pots. Place the written label facing the cuttings, following the same plan with all. When that is understood there will be no difficulty in knowing to which the label refers if there are several varieties in one pot. Employ small smooth labels of uniform size, lightly covered with white paint. Commence the writing of the name from the top, using a bold black lead pencil. Painted wood labels all ready for use may be procured cheaply. Those 3, 4, and 5 inches long may be bought at 6d., 8d., and 10d. per hundred respectively.—E. D.

NEW CHRYSANTHEMUMS—INCURVED VARIETIES.

CONTINUING from page 606 my selection I find numerous additions to this section, but whether they will rank as high as some in years past is a moot point. However, it is now too late to remedy that for this season; growers must perforce make the best of what material comes to hand. By these remarks it must not be inferred there is none deserving of cultivation; certainly none comes up to the high standard of excellence set by such as Lord Alcester or the various members of the Princess of Wales family. There are, however, several that will prove useful and interesting to cultivators when next November comes round, and which those who aim at the highest pinnacle in the exhibition world cannot afford to do without.

As far as I can gather, every new variety of this season has been obtained from the seedling source; not one is the result of a sport. This, in my opinion, is the cause of a want of decided excellence in the newer sorts of the last season's introductions. Prominent in the list should

stand the two varieties raised by Mr. Foster, Brockhampton Nurseries, Havant, and named after members of his family.

Miss Violet Foster.—This is of American origin, and is a promising variety. The blooms are full size, especially well built; the slightly pointed florets incurve perfectly. The colour—dull purple on the reverse, faintly edged with silver—is distinct.

Miss Dorothy Foster.—A decided acquisition. The formation of the blooms is almost perfect. The florets have a distinct resemblance to Jeanne d'Arc in formation, being chipped at the edge. The colour is rose tinted with silver.

William Sparks.—Introduced as an incurved Japanese. This was shown as an incurved variety during the past season, and if some elasticity is to be allowed in this section, exhibitors would do well to add this to their list. The reverse of the slightly pointed florets is deep lilac flushed with silver. The blooms are large and of good form.

Mrs. James Eadie.—One of Pitcher & Manda's seedlings, distributed by Mr. H. J. Jones. The blooms are large and of good form, some few florets are at times slightly hirsute. The colour, lilac pink, is pleasing.

General Maurie.—Raised in 1894 at Ryecroft Nursery, this resembles in some degree of petal formation Jeanne d'Arc, except, perhaps, in the new variety the florets are stouter. The colour is soft primrose, each floret is tipped yellow when opening. This is a promising addition.

Lyne, jun.—This is from the same source as General Maurie. In colour chestnut and yellow at the base, golden or dull yellow in the centre. The broad florets incurve regularly.

Bonnie Dundee.—A favourable opinion was arrived at of this last season. The formation is perfect, the colour most pleasing—yellow heavily suffused with bronze, with an additional shading also of mauve.

J. H. Runchman.—When properly cultivated this would be admissible in the incurved section. It is now classed as a Japanese incurved, but is much too small to take a high position in that class. The florets are slightly chipped at the point, incurving perfectly; orange yellow. In late blooms the bronze shading is pleasing.

George Haigh.—Though not exhibited many times this year, sufficient blooms were seen to justify the high opinion formed of it last year. The form is of course identical with that of its parent—Robert Petfield—from which it is a sport. It is a full, handsome bloom, rosy carmine, centre shaded gold.

Duchess of Fife.—This has of late been the subject of some comment in the horticultural press; it was certificated as a Japanese incurved. The prevailing opinion, however, seems to be that it should be relegated to the incurved section. Certainly it was as such that I staged it for consideration by the N.C.S. Floral Committee. In the Japanese section it will be useless, being too small for present day requirements on the exhibition table. As a back row bloom in the incurved section it should take a high position. The blooms are quite globular, with long, closely incurving florets, tapering at the point. Early formed buds give pure white blooms, later are flushed with pink. It is of easy growth, carries abundant foliage, and is a credit to the raiser—Mr. H. J. Jones.—E. MOLYNEUX.

(To be concluded.)

THE GLAD NEW YEAR.

FAR be it from us to say a word against our old friend just passed away, but still we all must admit there is room for improvement in 1897. But it is not alone improvement in the seasons we hope for, there must be improvement in ourselves. Good resolutions are excellent, but there is always a danger of making far too many; a few well carried out build up the character much more.

We may look upon this New Year in two ways. First it comes as a gift of time direct from "The Lord and Giver of Life." We have been spared to make a fresh start, to turn over a new leaf; our names are not on the list of those good men and true for whom time last year merged into eternity. We are left to carry on our work and theirs; we have their example as a stimulus to fresh effort.

Much as some of us may crave for rest, still when a long mortal illness comes some thoughts must be very saddening. No more shall we tread the old familiar garden paths, no more pluck the flowers our hands have planted, no more will the song of birds reach our dull ears; other hands will work where we worked, other hands will reap the fruit of our toil, and our place shall know us no more. Glorious as may be the immortal flowers, very dear to our hearts are the humbler denizens of the earth.

We have begun the year, let us not at the close (if we are spared) have to look back regretfully on one wasted minute. There is an old motto which will bear repeating, and one that we should do well to write on our hearts—"Lost, somewhere between sunrise and sunset, one golden hour, set with sixty diamond minutes. No reward is offered, for it is lost for ever."

Then time comes as a talent—a talent to be put out to usury—no one is expected to work beyond his powers. Can we faithfully say that we always work up to our powers? It is wonderful the blessedness that comes with faithful work. This work must not be selfish in its character; we ought all to be members of one vast "Mutual Aid Society." It is generally the busiest man who can

do the most for others; the idle man is so behind with his own work that he has neither time nor inclination to help a neighbour. There are always opportunities at our door if we will but seize them, and it is not (thank God) the great things that count the most.

The master craftsman by a look, word, or smile may encourage a young brother, and spur him on to greater effort. A quiet appreciative listener may ease the burden of an overworked harassed soul. It always does one good to hear of similar difficulties being overcome, and it is wonderful what ideas and suggestions arise when a knotty point is quietly discussed with a tried friend. If the old hands can thus be of some service to their younger brothers, these striplings, too, may find work to their hands. The cheerful surrender of a well-earned leisure to help with a planting or pruning job in a neighbouring garden is a helpful discipline which must have a good effect on the character. If the young 'un has had a little technical training he ought to have many items of useful information for an outsider. The loan of a book or newspaper, the gift of a cutting or a few seeds, are all channels by which he may enrich those around him, and raise himself out of the slough of self.

In the lot of all come dangers, but one of the greatest dangers of modern times is the desire to do away with difficulties. This looks like a paradox. Is a life of ease the best and highest kind of life? No; it is only by fighting difficulties that the character is formed. Kingsley used to sing of "the brave north-easter" that made Englishmen what they are, and he got at the true spirit of the thing. Which is the finer man—the soldier perfect in autumn manoeuvre, with the drill at his finger's end, or the man who has led his little force through a hostile Afghan pass, or within range of a Zulu assegai?

Why, it is the very fact of our uncertain treacherous climate that has called forth the best efforts of our horticulturists. There is no credit in gardening where Nature does all; our young men expect so much more than their fathers; they are like the daughter of the horse leach, they cry, Give, give. Mind, we believe thoroughly in one form of discontent—discontent with ourselves, a discontent that leads to diligent effort and greater endeavour. The higher the attainments, the greater the humility. The book of Nature is so large that even those who have studied the longest leave much of the lesser unlearned. Remember time is short; you have no guarantee of another year. "Work while it is called day, for the night cometh when no man can work."—THE MISSUS.

OUTDOOR CULTIVATION OF MUSHROOMS.

HAVING grown Mushrooms in the open air for several years past, a few notes on the subject may be of interest to those who have not tried this system of cultivation. I was tempted out of the beaten track of growing Mushrooms in houses by having a copy of "Mushrooms for the Million" placed in my hands, and no apology is needed for referring to this admirable work in these pages, as it should be in the possession of all who wish to excel in the cultivation of this esteemed esculent. We possess one of the best Mushroom houses in the country, but it is rarely used for the purpose it was originally intended owing to the better crops and superior quality of the Mushrooms grown in the open air. It is an advantage to make up a bed in the house in the autumn, when Mushrooms are required daily at midwinter for home consumption, as during severe weather the outdoor bed should not be disturbed more than is necessary.

WHEN THE BEDS SHOULD BE MADE.

September is the most suitable month for a beginner, but with a little practice as good results may be obtained from beds made up during the present month as at any other season. Early in the autumn of 1895 I made up several beds which were not so satisfactory as those prepared three months later. This was owing to the hot weather experienced throughout September. Two years ago at midwinter, when the thermometer registered nearly 30° of frost, some beds were made and spawned during the severe weather, and some of the best crops of Mushrooms we have ever grown were obtained. If Mushrooms are grown for market it is not advisable to make up beds after January, otherwise the produce comes in when prices are low, and should warm weather prevail the beds will soon become exhausted.

PREPARING THE MANURE.

This is the most particular part of the business, and is the stumbling block over which many fall. One of the chief mistakes that is made is in not having the manure sufficiently moist. Manure prepared for beds made up in the autumn should be very moist, whereas when used at midwinter it should be in a much drier

state. After the last beds are made up in January all the manure that comes to hand should be placed in a heap, and kept in the open air until required the following autumn, only the long litter being shaken out, which will keep in better condition if placed under cover, as it will be required for covering the beds after they are made. The manure after being in a heap for six months will become very dry, as it should be stacked so as to throw the water off. It will be little the worse for this, as after it has been turned over and shaken out, well moistened, and carefully turned three times a week, decomposition will be rapid; if the work have been properly done the material will be in a suitable condition for growing Mushrooms. If the manure that is obtained during the autumn is placed in a heap in the open air no water will be required, as there is then a danger of it becoming too wet from the excessive moisture at that season.

Leaves, if used in the proportion of one part to three parts of manure, are of great assistance, not only in the saving of manure, but in keeping up a steady heat in beds that are made at midwinter. Oak and Beech leaves are the best for that purpose, and should be well incorporated with the manure during its preparation.

MAKING THE BEDS.

The ridge system is preferred to any other, and there is no advantage in making them too large, as a much larger quantity of manure is required, without a corresponding increase in the crop of Mushrooms. I have experimented with various sized beds, but have now come back to the size I originally commenced with—namely, 2½ feet wide at the bottom, 2½ feet in height, and 6 inches wide at the top when finished off. Beds of this size will retain sufficient heat to grow a heavy crop of Mushrooms, and that is all that is required. Although residing in a northern county, I have no hesitation in recommending the above sized ridges in preference to larger ones. The beds should be made as firmly as possible by treading, and beating the sides with forks as the work progresses. Men soon become experts at the business, and when they take a pride in their work will with a little practice build the ridges as true in outline as the roof of a house.

COVERING AND SPAWNING THE BEDS.

This should not be delayed, but they should be at once covered with a few inches of the long litter that was previously shaken out of the manure. It is advisable to leave the top of the ridge clear, so as to allow the steam to readily escape. If the manure have been properly prepared and the beds well made they will be ready for spawning in ten days. This can be ascertained by placing a thermometer in the manure. In a few days after the bed is made up it will probably register 100°, more or less; after it has fallen to 80° it is safe to insert the spawn. If there is any doubt in the matter it is better to wait a day or two than to do so an hour too soon. I am convinced there is more harm done in being in too much haste in spawning the beds than in allowing them to become too cold. The spawn is then blamed, whereas the cultivator is at fault. The mycelium being very delicate is destroyed within a few hours after being inserted in the manure if the heat is at all excessive. I had a practical illustration of this a few years ago.

Having obtained some manure solely from entire horses it was kept separate, and placed at one end of a ridge, spawn being inserted in due course, at the same time the remainder of the bed was done. A thermometer was placed on the surface of the ridge, but not at the end where the entire horse manure was used, until suspicion was aroused. On the third day after spawning a thermometer placed on the surface at the end of bed registered 90°, the remainder of the bed being only 60°. The latter did remarkably well, but the former was a failure, clearly showing that the spawn was destroyed in its early stages. A cake of spawn should be divided into eight parts, and be inserted about 9 inches asunder, slightly covering it with manure, which should be made quite firm.

CASING THE BEDS.

Some growers delay the casing of the beds with soil for a few days until the spawn has commenced running. I cannot see any benefit in this, while it is an advantage at this season to retain the heat in the beds as long as possible. I therefore always case the beds with soil as soon as they are spawned, using good loam that has been stacked for a few months, chopping it fine, and if dry water is added. The beds are covered with about 2 inches of soil, placing it evenly and firmly over the surface. This requires a little practice; never having seen it applied to ridges we had a difficulty at the first, but soon found out how it was done, and now it gives us no trouble.

PROTECTING THE BEDS.

The ridges must be well covered with litter or straw. At the present time ours are covered up warmly with litter about a foot

in thickness; some are thatched, and as the thatch is machine-made it is easily rolled off and replaced when necessary. Others have waterproof coverings. The only objection I have to them is that the moisture condenses under them, which causes the litter to decay more rapidly than it otherwise would, and as straw is now an expensive item it is an advantage to roll off the coverings during fine weather.

Mushrooms appear in from six to twelve weeks after spawning, according to the temperature of the beds.—S., Yorks.

THOUGHTS ABOUT FRUIT GROWING.

So much has been written on the subject of fruit culture during recent years, and capable men have been hammering away on the importance of better methods and closer attention to detail in regard to the production and distribution of home-grown fruit, that we look round to see what results have been the outcome of this action. The question naturally arises, Who are the principal fruit growers of this country? Some may answer gardeners, and certainly they comprise a large proportion, but should be classed rather in a professional than in a commercial sense. Fruit growing is part and parcel of the gardener's occupation—often his pet hobby; he has a reputation to maintain in that respect, and it is therefore to his interest to make himself acquainted with the best varieties, the most efficient methods of cultivation, and so forth, in order that he may win honours for himself at the exhibition table or receive approbation from the dining-room—both objects being worthy of his best efforts. High quality is the end in view, and this no doubt is responsible for the fact that hardy fruit—Apples, for instance—grown in private gardens or nurseries, where they are made a speciality, are so much superior to the generality of fruit sold in the markets.

Take for instance the great fruit show at the Crystal Palace. Mark the excellence in size, form, and colour of the hundreds of dishes exhibited. Who will say that such fruit is not equal in quality to the best of any other country? Ask where they are grown, and you will find that almost without exception fruit nurseries and private gardens are responsible for the whole. Tarry awhile till the great show closes, and watch the anxious almost greedy crowd pressing round the tables to buy, and the greatest difficulty an exhibitor experiences who wants to take his fruit home is to keep them from buying. Most of the purchasers know little about fruit, yet sufficient to tell them that the show fruits are cheap at any price compared with the inferior specimens that are expected to help to pay the rent of a still greater class of fruit growers—English farmers.

This brings us to the point, Why do writers hammer away on the subject of fruit culture? why do practical men demonstrate? and why do corporate bodies use all the means at hand to teach better and sounder principles? Is it to instruct gardeners and those who exhibit at such shows as the one in question in work in which they are already competent? No, certainly not; but rather it is for the benefit of a class who rarely attend, and never exhibit, at shows in work which is of such great moment to the future of land cultivation. Why fruit culture should be considered of such minor importance to the average farmer it is difficult to say. He will tell you that it doesn't pay; he can't sell his Apples in the face of American produce, and it's no good bothering with them. But question him further to get at the root of the matter. You will probably find him conversant on the subject of stock breeding and rearing, dairying, and the management of root crops, but in the orchard he is quite at sea. The trees are there of course, but he does not know who planted them, varieties do not trouble him, he knows one or two by local names, and is surprised to hear that the trees being covered with moss and lichen growth is detrimental to their welfare. Need we wonder then that foreign trade prospers, and our own declines, when conservatism and lethargy are so apparent?

Whether Britain will ever again be classed as a fruit-growing country is an open question. Possibilities there are no doubt, but it is questionable whether the men are forthcoming from the present generation. To persuade the farmer to give up his dairying and his root growing, and go in for fruit culture, would be a foolish policy; but to class this industry as an important section of his occupation is another matter, for it is as an adjunct to other crops that fruit culture on proper lines would prove the most profitable to the farmer. "Never have all your eggs in one basket" is an old saying, which in every sense is applicable.

No body has done more to help forward the movement for better and more systematic methods of fruit culture than the Royal Horticultural Society. A visit to the Crystal Palace show proves the appreciation of its efforts, but only in one direction—viz., professional gardeners and nurserymen. Could not our Society,

and the sister one, the Royal Agricultural, join hands in this matter and do something more? In this respect their interests are mutual, and I see no reason why classes could not be introduced at the Palace show for Apples and other fruit open only to *bona fide* farmers. Surely there must be many in the great army of agriculturists who would take advantage of such an opportunity, and it would also be an inducement for others to visit our shows. It is from small beginnings the great things grow, and for this reason such a thought is worthy of consideration. While agri- and horticulture are looked on as being quite distinct we cannot expect great things in this direction, but when this barrier is broken down, and it becomes more fully recognised that their interests are mutual in many respects, we may look for the gardener and farmer to join hands in the common interest.—G. H. H.

(To be concluded.)

VELTHEIMIA VIRIDIFOLIA.

THIS is a greenhouse bulbous plant not commonly seen or cultivated. It forms when in flower a very effective decorative plant in the conservatory or greenhouse, the spikes of drooping red and yellow flowers lasting in good condition a considerable time at the present season of the year, which is its natural time of blooming in a warm conservatory. Cooler treatment will retard its blooming until February or March, so that with several plants it is possible to provide a successional display. The *Veltheimia* is not, however, a very popular plant, as the spikes of bloom or even the individual flowers are of little or no use for cutting. Hence a few plants are usually all that are cultivated or required in a large establishment.

Like many other of our uncommon bulbous plants the *Veltheimia* is a native of South Africa, from whence it was introduced to this country in 1768. The bulbs with good cultivation attain to the dimensions of large Onions. The leaves from such bulbs are correspondingly large, long, and leathery; but they will not endure rough treatment, which causes them to break transversely, spoiling to some extent the appearance of the whole plant.

The bulbs rest during summer, new growth commencing again in August. That is the best period to pot the bulbs or shake away the soil from those occupying pots in which they may have rested. Select pots according to the size of bulbs, draining them moderately. Prepare a compost of rich turfy loam two parts and well decayed manure one part, adding a little sand also. Place soil in the pots and then the bulbs, so that the points of each are just below the surface when sufficient soil has been introduced and pressed firmly therein. The soil being used in a moist state it is not necessary to water heavily at first, but as growth becomes free the supplies should be increased, never allowing the soil to become dry, especially when the roots fully occupy it. Weak liquid manure may be applied occasionally, and it will assist in improving the colour of the beautiful glossy foliage as well as strengthening the bloom spikes.

A temperature of 45° to 55° is ample for the continuance of healthy growth, plenty of light and an airy atmosphere also being essential. Crowding the plants among or under the shade of others tends to make the leaves brittle and the flower spikes develop weakly.

The best position for the plants after potting is undoubtedly a cold frame where they can have a position near the glass. As the plants increase in size take them to more roomy quarters in a greenhouse, allowing them there to remain during the rest of their period of growth, both before and after blooming. The plants should mature in full sunshine. When the leaves have died down the bulbs may rest in any dry corner in greenhouse, keeping the soil dry.—E. D. S.

BRIEF NOTES ON ALPINE FLOWERS.

(Continued from page 610.)

PROTECTING WINTER-FLOWERING CROCUSES.

"WHAT can I do to protect my winter Crocuses from wind and rain?" This is what is not infrequently asked, and it cannot, if fairly considered, be deemed a superfluous query. "Cover them," is a reply good enough in its way, but, like many other replies, not sufficiently definite. "With what shall I cover them?" would almost inevitably be the next question, and this, again, could not be thought unnecessary. Let us, then, talk over the matter from a practical point of view.

It is sufficient with many flowers in winter that they should have a sheet of glass above and a free current of air passing between the glass and the plant; but unless in very sheltered gardens this will not do for the Crocus. In the wild days of winter the flowers are soon blown down by the strong winds, which seem to do all the more mischief if they get below the sheet of glass—at least the flowers are more easily destroyed by the wind even if saved from the rain. What is to be done then? "A small bell-glass," say some. Unfortunately, these little glass domes are rather too expensive to be employed on a large scale. They are also not very difficult to break, and take up a good deal of space when put away for the time. Unless lifted up a little, too, they do not give enough of air if the sun shines, and the atmosphere inside is heated to an excessive degree. Small hand-lights are expensive, and a simple wooden frame with sliding sheets of glass is the best thing for the purpose. If not too large (and there is no need for this) waste pieces of

glass may be used, and the covers made at very little expense. Later in the season they may be used for other purposes. A drawing and particulars of two of these accompany this. It will be seen that air can be given on a side opposite the wind.

SHELTERS FOR EARLY BULBS.

FIG. 3.—G, Glass sliding in grooves cut in the wood of which the frame is made. The wood is about 1 inch square. Size of shelter shown is 8 inches by 8 inches and 6½ inches high, but these dimensions can be altered. The glass on the top and two sides is shown partially drawn.

FIG. 4.—This is an older pattern, with glass top (G) sliding in a groove cut in top of wooden side, S. For further ventilation the sides D turn on wire nails N, and close against strips of woods connecting the two sides S at bottom. The size of this shelter is about 8 inches long by 8 inches broad, and the same in height. The wood is about ¾-inch thick. The opening sides are shown partly open.

AN EARLY SAXIFRAGE.

One of the earliest of all the Saxifrages is full of flower buds, and promises to be attractive early in January. If the impression regarding aliases which prevails with respect to men and women is to be taken as holding good about flowers, what an evil character this plant would bear! But the truth is that it is in no way responsible for others' misdeeds, and it is through no fault of this Saxifrage that it has had no fewer than four names, and that it obtained honours from the R.H.S. under an assumed one. Its real name is admitted to be *S. apiculata*, but its synonyms are *Frederici-Augusti*, *luteo-purpurea*, and *lateo-viridis*. It can stand a good deal of hard weather—frost, snow, or rain—and the only advantage it receives from being covered with a sheet of glass is that the flowers are of a brighter primrose yellow than if left uncovered. Some say, "Divide it every year to get it to flower freely." Do not do anything of the kind unless it persistently blooms unsatisfactorily. In many gardens it flowers perfectly well without such drastic measures, and is surely much more beautiful when it grows into a big mound of grey green with little spikelets rising above and showing their little yellow flowers.

EUPHORBIA CYPARISSIAS.

This is sometimes recommended as a plant for rockeries, and one is led to wonder if the one who recommends it has had it long or has plants to sell. It has pretty foliage, and its flower bracts are of a green which has sufficient yellow in it to make it bright. It is easily grown, and will cover a rockery in a very short time. All this is true, but all the same one feels sorry for the unfortunate beginner who is deluded into putting this *Euphorbia* among his choice rock plants. We all do very foolish things when in our "salad days" and green in judgment, and the harvest is generally reaped afterwards. We introduce the wild Oats and grumble later. The writer knows a rock garden into which this Milkwort was introduced through its forming one of a "cheap" collection of rock plants—"vendor's selection." The Cypress Spurge is somewhere described as "an elegant plant of perfect hardiness, and succeeding in any soil or situation."

We shall not pick holes in the description, but all the same, gentle reader, we beg of you, do not allow yourself to be induced to buy it. The unfortunate amateur who owns the garden mentioned above bought *E. Cyparissias* some ten or eleven years ago, and for some eight or nine he has been endeavouring to get rid of it. He is still at the work, and begins to think it will occupy some of his leisure for the remainder of his natural term of life. It runs under the surface, making use of stones as fortresses, whence it may sally forth among the gems beloved of the man who has gone crazy over alpine flowers. A little bit will grow, and it must be set down as one of the flowers to be fought shy of.

EDELWEISS.

The romantic interest of this flower seems to cause it to be more eagerly sought after than its intrinsic beauty would merit, compared with many other gems of the mountains. Doubtless much of its value to the Swiss mountaineer is that of its "everlasting" nature, and that on account of this it may be kept as a remembrance of the marriage ceremony. I had better cut short this introduction to what is really the more prosaic question of the winter treatment of the Edelweiss, or I shall be in danger of incurring a remonstrance.

Well, then, the Edelweiss is hardy enough, but should be kept high up on the rockery, in light soil, and should have glass or a slate a few inches overhead to keep its woolly leaves dry. So I told a friend who had had some plants sent him, and who asked me what he could do with them. I fear, however, the steed was stolen, as it appeared that the plants were already on the rockery. The stable door was locked too late, as they were not in a very good place, and it was too far in the season to remove. Then it was going to be too much trouble to put the glass above, and I was told "they would just have to take their chance." What could one do but think that after all the inquirer would never become a grower of Alpines? He might grow *Euphorbia Cyparissias*, but the *Gnaphalium* is beyond his patience and so beyond his skill. —ALPINUS.

(To be continued.)

POINSETTIAS.

THE remarks by your able correspondent, "J. S. G." (page 586), prove that he is an enthusiast and a practical grower of the Poinsettia, and his article appears at the opportune moment when they are at the height of their season and popularity. That perfection in their growth and treatment is arrived at under varying conditions is admitted by your correspondent, and some growers no doubt may be inclined to take exception even to the methods described and adopted by "J. S. G.," excellent though his results may be, and undoubtedly are.

My observations, extending over several years, justify the opinion that no hard and fast rule can be universally adopted, but the grower must adapt himself to the conditions with which he is brought into contact. One cultivator will produce good material under cool summer and autumn treatment, while another secure the same satisfactory results under warmer conditions, and very often the latter course is adopted from force of circumstances rather than from choice.

The past summer certainly cannot be regarded as a typical one, the drought and heat being much above the average, so that the Poinsettias grown entirely in the open air may have been favoured; but in my case results clearly show that a three-months course in the open air was agreeable to them, their growth being short jointed and well ripened, and the resultant bracts, though not equalling the greater diameter of your correspondent's plants, are nevertheless of average size. Having cool treatment since they were placed indoors at the end of September, they are in good condition for house furnishing. Needless to say, it is only the old plants and the earliest rooted cuttings that have been given this cool outdoor treatment.

It is presumed that "J. S. G." admits there are at least two distinct forms of Poinsettia beside the double and the white one in general use. I know there are some gardeners who do not acknowledge this fact. There is not the least doubt of this, as anyone growing the two kinds can readily distinguish them. They are distinct both in point of size and form of bract, in habit of growth, and time of flowering. One will develop its bracts early in November under cool treatment, the other can be more easily flowered for the Christmas festival. One has a uniformly shaped head, the other is not so compact, and the colours vary almost as much as shape in the two forms. What their distinctive titles may be I cannot determine, but probably some other reader may be able to decide the point. It is a subject that may engage the attention of the young gardeners who contribute so well in the column set apart expressly for them. Mr. Robinson of Heywood and Mr. Mann at Leighton are both very successful growers of the late variety, and at each place a number of good plants may be seen at their best for the Christmas season.

During the twelve years Mr. Iggulden was at Marston Poinsettias were an annual feature, arranged while at their best in the fernery. There is nothing that I have yet seen that can surpass an arrangement of Ferns and Poinsettias, and grown as they were in various sized pots and of differing ages it was an easy matter to form perfect banks of their glowing bracts. Mr. Robinson retains none of the old plants after they have supplied the number of cuttings required, and as these are given frame treatment from the time they are well rooted until placed in their winter quarters the plants are comparatively dwarf and well clothed with foliage to their pots. Mr. Mann is a strong advocate for high temperatures to develop a good autumn growth and flower head. I have seen plants quite 6 feet in height bearing enormous bracts in 7-inch pots from cuttings rooted in May. I cannot give exact dimensions, but I believe I have measured them 22 inches in breadth. From a decorative standpoint, however, I consider a plant half the height, even if the flower-head is an inch or two less, much more effective, because they can be more easily seen and they are better adapted for grouping. At the same time, Poinsettias with heads nearly 2 feet in diameter are sure to win favours, and bestow credit on those entrusted with their custody. For securing such results there must be strong cuttings to start with and good accommodation for rooting them quickly. —W. STRUGNELL.

WEATHER IN LONDON.—As a whole the weather during the past seven days has been of a more settled character, though it is not yet quite seasonable. On Saturday a dense fog hung over the whole of the metropolis all day, occasioning much discomfort to everyone, and causing the trains at the various termini to be very late. It cleared towards eight o'clock in the evening, and at ten the stars shone brightly. Sunday and Monday were fine, but Tuesday was miserably wet. Wednesday was bright and clear, with a sharp frost in the early hours of the morning.

— WEATHER IN THE NORTH.—The close of the old and the beginning of the new year have been attended by variable, and by no means seasonable weather. New Year's Day was dry and brightish, the following day drizzly and cold. Monday was also fair, though cold; and on Tuesday morning there was the only slight touch of frost for the week then ending.—B. D., *S. Perthshire*.

— ROYAL HORTICULTURAL SOCIETY.—The first meeting of the Royal Horticultural Society in 1897 will be held as usual in the Drill Hall, James Street, Victoria Street, Westminster, on January 12th, 1 to 4 P.M. On or before that date the Society's new book of arrangements, containing particulars of the shows, lectures, Committees, &c., for 1897, and the report of Council, and new list of Fellows will be issued.

— REMEDY FOR AMERICAN BLIGHT ON APPLES.—I always read with much interest "Work for the Week" in the *Journal*, and in reference to the practical remedies for the above (page 634) I have found the following by far the most effective in my garden on Cox's Orange Pippin and Cellini, the former being of twenty-two varieties most subject to it:—Take a quart or a gallon of water, more or less as may be required, and boil it. Pour on freshly ground flowers of sulphur—the quantity in proportion to the number of trees affected—then mix well. When going to use take a tenth of petroleum and add. Then apply with a painter's brush, taking care to put plenty into the crevices. A second application may be unnecessary.—W. J. MURPHY, *Clonmel*.

— MR. CYPHER.—Hearty will be the congratulations to Mr. Cypher upon the attainment of the "allotted span," and earnest the common hope of his fellow townsmen and others that he will long be spared to preside over the flourishing business which has made his own name and that of Cheltenham so familiar in the horticultural world. In celebration of his seventieth birthday Mr. Cypher gave a complimentary dinner to his workpeople on Friday evening in one of the Orchid houses at his nursery off the Queen's Road. Mr. Cypher was present, accompanied by his two sons, Mr. William Cypher and Mr. Frank Cypher, and his two nephews, Mr. John Cypher and Mr. William Cypher, and the heads of the various departments. Altogether the company numbered upwards of seventy. During an interval in the songs Mr. Cypher made a characteristic little speech.

— PRESENTATION TO MR. W. MACKAY.—On the occasion of the completion of twenty-five years' service with Messrs. R. Veitch & Sons, Exeter, his fellow employes took the opportunity to present to Mr. Mackay an address (beautifully written and illuminated by Mr. F. Tozer), expressing the great esteem in which he had always been and is now held by them. The address was accompanied by an exceedingly handsome solid silver cigar case and vesta box, richly engraved with his monogram and bearing a suitable inscription. These were presented, on behalf of his fellow workmen, by Mr. Webber in a neat and appropriate speech. At this juncture a parcel was handed to Mr. Mackay, which, on being opened, was found to contain a very handsome solid silver salver with a cheque for £25 as presents from Mr. Veitch to commemorate the occasion, and "in recognition of twenty-five years of faithful service to the firm." Mr. Veitch's gift was accompanied by a letter written in feeling terms, expressing his appreciation of the value of Mr. Mackay's services, and hoping that the cordial relationship which had existed for so long might continue for many years to come. The recipient of these good wishes feelingly replied, and expressed his warm appreciation not only of their kind gifts, but still more of the kind words and manifestations of goodwill which accompanied them.

— **FORCED RHUBARB.**—Mr. H. Clayton, head gardener at the Manchester Reformatory School, sends us a sample of Rhubarb such as he has been pulling for five weeks. It is excellent. The stalks are 15 inches long, stout, bright red, with small green leaves. We are not surprised to hear that it finds a ready sale, though American Apples affect the price of the Rhubarb. "One of the Boys" informs us in an extremely well written letter, that he and fifteen other young workers presented a dinner service as a mark of their esteem to Mr. Clayton on the occasion of his marriage, on the 28th ult. The institution is evidently doing good work.

— **THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—A meeting of the above Society was held in the Parish Schoolroom on December 29th, Mr. George Picker (Hesslewood) in the chair, when a paper was read by Mr. G. C. Coates, gardener to W. Wheatley, Esq., Hull, on the "Arrangement of Plants in General for Effect." This included the planting of herbaceous borders and flower gardens, the arrangement of plants in glass structures and grouping for exhibitions. Much might be said about this arrangement of plants in gardens, and every gardener should become thoroughly conversant with this interesting branch of horticulture, by which means their gardens would be rendered more attractive and a source of much pleasure to their employers.—F. L. T.

— **RHODODENDRON GRANDE.**—Of the many beautiful Himalayan Rhododendrons this certainly ranks among the foremost. If it were grown merely for the sake of its foliage it would be worth a place in a cool conservatory, as the leaves average from 10 to 12 inches in length by 5 inches in width. As a flowering plant, however, it takes a front place in a genus composed almost entirely of good flowering garden plants. The individual flowers are about 2½ inches long by 2 inches in diameter, white in colour, with a dark blotch at the bottom of the throat, and produced fourteen to sixteen in a truss. A plant 9 feet high and 9 feet in diameter, carrying upwards of forty trusses of expanded and partially expanded blossoms, may now be seen in flower in the temperate house at Kew.—W. D.

— **EMIGRANTS' INFORMATION.**—The January circulars of the Emigrants' Information Office and the annual handbooks show the present prospects of emigration. According to the report of the Labour Bureau at Sydney the number of unemployed persons is still considerable. The selection of land by small settlers is proceeding very satisfactorily throughout the Colony, especially in the Riverina district. A report from the rich valley of the Hunter states that there is a demand for skilled farm labourers and dairymen, but none for mechanics or miners. Another report from the valuable dairying district of Kiama, south of Sydney, states that there is no demand for labour; land there is selling at £24 an acre, and renting at 30s., so that farmers going there require some amount of capital. At Robertson (102 miles from Sydney) there is a fair demand for farm labourers, and at Hay (450 miles from Sydney) for boundary riders, drovers, and country carpenters and blacksmiths. The Commission appointed to inquire into the financial failure of the Mildura Irrigation Colony has reported that it was mainly due to the insufficiency of the irrigation works, and that the Government contributed to this result by its neglect. They recommend that a loan of £30,000 should be advanced by the Government on security of the land, and that the original concession to Messrs. Chaffey should be cancelled. There are excellent openings for farmers, dairy farmers, fruit growers, and wine growers, if they have a little capital and some experience of the country. In South Australia, owing to the want of rain, especially in the north, farmers have greatly suffered, and the demand for agricultural labour, for shearers, and for general hands throughout the Colony has been small. In Western Australia there has been a marked scarcity of farm labour in agricultural parts in the south-west of the Colony. The wages of farm hands have advanced during the past two years in some districts as much as 50 per cent., and for some time to come there is likely to be a good opening for this class of labour. Employment, however, is not permanent in all parts, and in the Kimberley Division and other parts in the north of the Colony there is no demand. In any case emigrants should be prepared to turn their hands to all kinds of farm and station work, to cut down timber, use a pick and shovel, and to rough it in the bush and country districts. Intending emigrants are warned against emigrating to Chile without first verifying at this Office the statements circulated by colonisation agents. Owing to misrepresentations unsuitable emigrants have been sent from this country to the Island of Chiloe, and distress and discontent have been the consequence.—(Emigrants' Information Office, 31, Broadway, Westminster.)

— **MY GARDEN DIARY FOR 1897.**—Under the above title Messrs. Sutton & Sons send us from Reading what we may appropriately term an attractive and useful gardeners' and amateurs' companion. A list of concise reminders is given for each month, with an almanack and space for memoranda, which will prove serviceable throughout the year.

— **DEVON AND EXETER GARDENERS' ASSOCIATION.**—The annual supper, which has now been held by the members of the Devon and Exeter Gardeners' Association for some years past, took place recently. The chair was taken by Mr. G. B. Lansdale, while the vice-chair was filled by Mr. W. Andrews. The Chairman having submitted the loyal toasts, which were accorded musical honours, gave the toast of the evening—viz., "The Devon and Exeter Gardeners' Association," coupling with it the names of Messrs. W. Mackay and C. H. Clarke. Other toasts were submitted, and a most enjoyable evening was spent.

— **CHRISTMAS, 1896.**—Very few persons probably take the trouble to keep accurate account of the nature of the weather which prevails on each Christmas Day. If they did so, rather than trusting solely to memory, which may be very treacherous, they would probably find variations as great as probably any day of the year would furnish. Not that it is assumed that Christmas Day, or simply the 25th of December, is or should be of more importance than any other day, but there is no day in the year which the artist and the poet have so much marked for their own, and around which they have thrown such a halo of romance—always of an intensely wintry aspect. But it is rare that the romantic ideal of snow, hoar frost, and all these wintry concomitants is realised. Far more often is Christmas of a very prosaic order, so far as weather is concerned, such for instance as marked the present year's festival, when a heavy rain overnight literally washed all romance out of Christmas Eve, and made the famous wassail bowl to overflow with water. Christmas Day was soft, pleasant, and very much like the weather of early April. How diverse from the ideal weather, and yet how very like that which commonly prevails. It is this singular diversity between the real and the sham Christmastide which is telling so much towards the destruction of all Christmas romance. We are after all a very practical people, and hate thaws, hence we are getting to regard Father Christmas as something of an old humbug. The most real aspect of Christmas is found in its family gatherings. That is a delightful feature, which will long endure after fictional Christmas weather has been forgotten.—A. D.

— **THE APPLE AS A PROPHYLACTIC.**—Many can testify from actual experience to the value of the following, which appeared originally in the "New York Merchants' Review." "Everybody ought to know that the very best thing he can do is to eat Apples just before going to bed. The Apple has remarkably efficacious medicinal properties. It is an excellent brain food, because it has more phosphoric acid in easily digestible shape than other fruits. It excites the action of the liver, promotes sound and healthy sleep, and thoroughly disinfects the mouth. It helps the kidney secretions and prevents calculous growths, while it relieves indigestion, and is one of the best preventives known for diseases of the throat. No harm can come to even a delicate system by the eating of ripe and juicy Apples before retiring for the night."

— **THE PEAR SLUG.**—Pear trees have been severely injured in some portions of Delaware by the larva of this insect, *Eriocampa cerasi*, during the past season. This slimy, dark green slug eats the soft tissues of the leaves, leaving the coarser veins, and the mutilated foliage dries up and falls in midsummer. The insect can easily be checked by sprinkling the trees with air-slaked lime, or hellebore can be applied dry or in water. Road-dust has often been used with success, the efficiency of its action depending on each slug receiving a coating of the dust, which stops up its breathing apparatus and causes its death. The effect of the defoliation of a Pear tree in midsummer extends further than the immediate loss of its leaves. The dormant buds, which normally produce the foliage and flowers of the coming season, may push forth and cover the tree with a new foliage in August or September. Then a new set of buds are developed on this late growth to provide leaves for next year, and these buds are necessarily weak and undeveloped, and result in a feeble growth. This extra effort on the part of a tree, after its growing period is practically over, is a devitalising process, and if continued three or four years may result in its death. I know of one valuable bearing orchard that was quite destroyed by this pest in three years. Several young orchards have come under my notice which have gone, or are rapidly going the same way.—G. HAROLD POWELL (in "Garden and Forest.")

— PLANTS FOR DRY CHALK BANK.—Can any reader assist me in deciding what plants would thrive best on a now barren (grass) bank, situated on the Surrey hills, southern aspect? Soil about 4 inches deep, light loam, with subsoil of chalk.—G. K.

— DAHLIA MISS WEBSTER.—Referring to this new white Dahlia, which during the autumn of 1896 received so many certificates and a R.H.S. award of merit, Messrs. Dobbie & Co. desire to say that the raiser was Mr. William A. Kent, Newchurch, Sandown, Isle of Wight, from whom they obtained the stock.

— SWEET PEA "CUPID."—I have failed entirely in flowering the dwarf Sweet Pea "Cupid" either in the open border or in pots. In summer flower buds were produced, but dropped as soon as they expanded. At this time of year nothing but tendrils come where the blooms should be, though the plants are fairly vigorous. Plants covered with bloom have been exhibited. What is the secret of growing them? —ROSS-SHIRE.

— DEATH OF MR. J. W. C. HOWE.—We regret to have to record the death of Mr. J. W. C. Howe, which occurred on December 27th, the result of an accident at Brading Station, Isle of Wight. He was the son of the late Mr. Charles Howe, many years gardener at Benham Park, and nephew of the present gardener. The deceased (aged nineteen) was a promising young man, apprenticed to a firm of engineers at Newbury, and was spending his Christmas holidays with his widowed mother. Among the many floral tokens at the funeral were one from the Dowager Lady Sutton and one from Mrs. Myers of Benham.

— WAKEFIELD PAXTON SOCIETY.—The proceedings at the weekly gathering of the members of the Paxton Society on the last Saturday in 1896 were on totally different lines to those on other Saturday evenings. Instead of an essay or lecture on some horticultural or kindred topic there were a smoking concert and a substantial supper. Mr. W. Tunnicliffe, of The Poplars, Thornes, presided, and the vice-chair was filled by Mr. B. Whiteley, of Caxton House.

— THE WONDERS AND ROMANCE OF INSECT LIFE.—At the London Institution recently Mr. Fred. Enock, F.L.S., delivered a most interesting lecture on "The Wonders and Romance of Insect Life" as portrayed in the life histories of some of the insects common in every London back garden. The fifty illustrations shown upon the screen were the handiwork of Mr. Enock, each one a study from Nature, showing the metamorphoses of the various insects. Many of the marvellous insect egg parasites have been discovered by the lecturer, who is engaged upon a monograph of this most interesting but neglected family.—("Knowledge.")

— SHIRLEY GARDENERS' ASSOCIATION.—At a recent monthly meeting of this Society, held at the Parish Room, Shirley, Southampton, the President in the chair, the attendance was smaller than usual. Mr. E. Molyneux, Swanmore Park Gardens, gave a most interesting lecture entitled "Fruit Culture under Glass," which was chiefly intended to be applicable to those who have to do with houses where it is attempted to grow fruit with flowers. Mr. Molyneux, therefore, took what he termed the "salient points" of the culture of Grapes, Peaches, Nectarines, and Melons. There was a good discussion at the close of the lecture, and a vote of thanks to Mr. E. Molyneux closed the proceedings.

— ADVICE ON FRUIT TREES—COUNTY COUNCIL TEACHING.—A short note was recently published on pruning fruit trees, and County Council teaching by so called Technical Instructors. Unfortunately the cases referred to are not alone. In one instance advice was given to plant in a new orchard one-fifth of Tom Putt Apples as standards, and one-tenth of Annie Elizabeth. The soil was most unsuitable for Tom Putt, and the second variety, as most fruit growers know, is a very shy bearer. The advice given gratis, and dear at that, was not followed, as the farmer consulted another person who had some practical experience in growing fruit for market, which is far better than theory, and varieties suitable to the soil and situation were substituted. In the same county pamphlets have been distributed amongst farmers and others intending to plant fruit trees, in which they have been advised not to prune the trees when planted, but to defer it until the following season. The consequence is that instead of a well-formed head of clean healthy wood there are thin stunted branches covered with premature blossom buds.—SOUTH WALES. [We know nothing about the soil referred to as unsuitable for the Apple Tom Putt, but Annie Elizabeth has proved a notoriously slow bearer, and is therefore not planted by experienced fruit growers for market purposes.]

— LAST YEAR'S RAINFALL AT BENHAM PARK, NEWBURY, was 25.17 inches. September was by far the wettest month with 5.43 inches, but upwards of 3½ inches fell in March and June and nearly 4 inches in December. Rain fell on 168 days. In 1895 the total was 23.55 inches on 120 days.—H.

— SUSSEX RAINFALL.—The total rainfall for December at Abbot's Leigh, Haywards Heath, was 4.70 inches, being 1.96 inch above the average. The heaviest fall was 1.06 inch on the 13th. Rain fell on nineteen days. Total for the year, 26.48 inches, which is 4.17 below the average. The maximum temperature was 49° on the 31st; the minimum, 25° on the 17th. Mean maximum, 43.07°; mean minimum, 33.18°. Mean temperature, 38.12—0.48° above the average.—R. I.

— DECEMBER WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected), 37.69°. Wet bulb, 36.87°. Mean maximum 41.73°; mean minimum, 32.98°. Highest, 50.0° on the 30th; lowest, 20.0° on the 1st. Mean of maxima and minima, 37.35°. Mean radiation temperature on the grass, 26.63°; lowest, 12.2° on the 1st. Rainfall, 3.97 inches. Number of rainy days, twenty-three. Greatest amount on one day, 0.66 on the 4th.—W. E. LOVEL, *Observer, York Road, Driffield.*

— DECEMBER WEATHER AT HODSOCK PRIORY, WORKSOP.—Mean temperature, 37.9°. Maximum in the screen, 53.7°; minimum in the screen, 18.4°; minimum on the grass, 10.7°, on the 18th. Number of frosts in the shade, sixteen; on the grass, twenty-six. Sunshine, twenty-three hours, or 10 per cent. of possible duration. Rainfall, 2.55 inches. Rain fell on twenty-two days. Maximum fall, 0.47 on the 4th. A dull month with no sharp frosts and with a slight excess of rain.—J. MALLENDER.

— LAST YEAR'S RAINFALL.—In this district (South Yorkshire) the drought during the past season was not so disastrous as in some parts of the country. The rainfall for the past year has been 23.90 inches, which fell on 167 days. This is quite up to the average of the past ten years, which was 23.71 inches, and fell on 167 days. In the previous ten years there was an average of 28.68 inches, which fell on 180 days, thus showing that the past ten years were drier than the previous decade.—GEO. SUMMERS, *Sandbeck Park.*

— DECEMBER WEATHER AT DOWLAIS.—The following is a summary of the weather here for the past month:—Sunshine, 25 hours 55 minutes. Sunless days, seventeen. Snow, 0.23 inch; rain, 9.48 inches, making a total fall of 9.71 inches. Greatest fall 0.94 on the 4th. Number of days on which rain fell, twenty-two, and snow on three days. Mean maximum for the month, 39°, with 47° on the 28th as the highest reading. Minimum 32°, with 21° as the lowest reading on the 16th. The wind was in the E. and S.E. on eleven days, and in the N. and N.E. on nine days. Totals for the past year:—Rainfall, 45.27 inches. Sunshine, 1223 hours 50 minutes. Sunless days, ninety-six.—W. MABBOTT, *Dowlais, Glamorgan.*

— EUCHARIS STEVENSI.—Beautiful and valuable at all times are the flowers of the old and well-tried *Eucharis amazonica*; but too few, I fear, sufficiently estimate the true worth of *Eucharis Stevensi*, one of the later additions to the family, for decorative purposes. The flowers are not so large as *E. amazonica* and are more erect, consequently they can be used in a variety of ways for bouquets and other floral decorations. It is a capital grower and free bloomer, whilst the dreaded mite does not seem to touch it. With a few good pots one is rarely without flower. After having tried many composts I cannot get anything more suitable than good Kentish loam mixed with sharp silver sand, the pots being well crocked. Owing to its being seen in too few collections I thought this note might bring a deserving variety into greater prominence.—R. P. R.

— SENECIO GRANDIFOLIUS.—Several large specimens of this handsome *Senecio* may now be seen in flower in the temperate house at Kew. For cool greenhouse or conservatory work this is a very useful plant. During summer the abundantly produced dark green leaves, which individually average 12 inches in length by 8 inches in width, are very conspicuous; whilst in winter, with the addition of large heads of deep yellow flowers (which open from December onwards through January and February) the plants are even more effective. Although this plant can be successfully grown in pots, it does much better if planted out, the leaves and flower heads being correspondingly larger through the more liberal treatment. After flowering the young growths should be cut back to within a few inches of the old wood. This species is a native of Mexico, and at Kew grows to a height of 10 feet.—W. D.

CATTLEYA PRINCE OF WALES.

THIS Orchid, which was added to the list of hybrid Cattleyas about five years ago, is of great beauty, but probably not very abundant, which would account for "Young Orchid Grower" (page 20) not having met with it. C. Prince of Wales is one of the most delicately beautiful that has yet been raised, which, considering

rubra oculata, the soft rosy shade of the former telling greatly in these dull dreary days. The spikes are not quite so fine as in former years, owing to alterations which interfered with the earlier stages of their growth, but still they are of the greatest value. I had intended sending you a few spikes of C. Veitchi, also a cultural note, but indisposition has prevented my doing so. I will do so at the earliest opportunity.—R. P. R.

HYBRID CYPRIPEDIUMS.

IN the second paragraph of my note on this subject, page 556, I should have made an exception in favour of C. Sallieri, as this plant certainly appears to be a natural hybrid between C. insigne and C. villosum. It has the dorsal sepal of the former, while the petals have the decided median line as seen in C. villosum, and also the shining brown tint peculiar to that species. C. Sallieri is named

FIG. 5.—CATTLEYA PRINCE OF WALES.

the number now in cultivation, is high praise. It is said to be the result of a cross between the white Cattleya Mossiae Wagneri and C. calummata. The plant shows characters that might be considered intermediate between the two parents; and there is no question that it is a delightful and valuable seedling. The sepals and petals are pure white, as also is the lip, with the exception of a series of pale rose veins in the centre, and a finely frilled margin. The woodcut (fig. 5) admirably depicts the form and markings of the flower.—ORCHIDIST.

CALANTHES.

WITH the advent of the many new Orchids that have appeared during the past few years we must not lose sight of the fact that many of the older varieties must be strictly kept in mind, and for winter work we shall have to look long ere we find anything to surpass the Calanthes. Our stove at the present time is a picture, with 6, 8, and 10-inch pots filled with Calanthe Veitchi and C.

after a French gardener, who was supposed to have raised it by crossing these two species, but who, as a matter of fact, selected it from other plants of C. insigne and sent it out as C. Sallieri. It has also been imported since by several orchidists, and not long since I saw a specimen of C. S. Hyeatum that flowered from an importation of C. insigne. This exception, however, does not alter the fact that natural hybrids in the genus are few and far between.

DENDROBIUM WARDIANUM.

The flowers of this beautiful and popular Dendrobe are now in full beauty, large plants with their long pendulous stems wreathed from end to end with the chaste blossoms having a truly delightful effect. Why some cultivators tie these stems erectly to stakes and other ugly contrivances I cannot imagine, for it entirely ruins them from a decorative point of view. It is certainly a cultural aid, for if the plants are properly fixed at potting time no support

of any kind is needed. Should the roots be scarce, and the plants in consequence difficult to make rigid in their pots or pans, a stake to one or two of the old pseudo-bulbs may be given, but the young shoots have fixed themselves by means of the roots long before any artificial support is necessary to them.

As a rule *D. Wardianum* commences to grow very early in the season. This necessitates the plants being kept in a good light, otherwise the shoots will be apt to damp off. Very little water will be needed until they commence to root on their own account, and just before this root emission is the most suitable time to renew the compost. Like most of the deciduous kinds *D. Wardianum* thrives best in pans or baskets of very restricted size, the small pans made for suspending, and now so much in vogue, answering for them very well. If baskets are used the plants thrive well, but are more difficult to remove than from the pans.

Half fill the pan with drainage, and fix the plants firmly in the usual peat and moss mixture. They must be taken at once to the warmest house at command, and a brisk moist temperature kept up all through the spring and summer. Only a very little shading is needed, and this of the lightest description, so that the plants in a manner ripen as they grow. The growth in most cases will be very rapid, and by August the terminal leaves usually appear. When the stems have quite done growing hang the plants in any light unshaded house for a week or two, and as the leaves begin to lose colour and fall lessen the water supply by degrees.

The ripening process is very important, and may be hastened by placing the plants out of doors in the full sun for a few weeks, protecting them only from the heaviest rains. They must not be kept absolutely dry at this time, but a very limited supply of water suffices. Take them under cover before any danger of frost is apprehended, keeping them as cool as possible, and after all the leaves are off quite dry. The plants may then have a long and complete rest; where there is a good stock introducing them to heat successively to keep up a longer display. They will require from six to eight weeks to come into flower, but by keeping quite cool and dry last a long time in good condition. By this means I have had them as late as May for exhibiting, but this is not conducive to the continued health of the plants, they not having time to get thoroughly ripe again before the winter.—H. R. R.

FLORAL FACTS AND FANCIES.—24.

THE world is full of music to those who have an appreciative ear, and one advantage of Nature's melodies is that they cost us nothing. Something may be said in favour of sounds that might appear harsh or unmusical if it were not for their surroundings, which make them agreeable. People have laughed at Cowper, because he said in one of his letters that, though he would not think of hanging up a goose in a cage to hear it at home, yet a goose upon a common was not a bad performer, but we may allow there is truth in the poet's remark. Again, amongst the sounds produced by the vegetable world the creaking of the trees in a wood during autumn winds is not unpleasing, yet within a confined space this would very soon be annoying. When much of England was fen and marsh it is probable our forefathers, even if semi-savages, were not unmoved by the murmurs of Reeds and Rushes, that of the former especially so common as an edging of streamlets—

"The Reed with its ringlets of waving brown,
Which age into locks of grey silky down,
Whose shafts ever sing to the softest sigh,
And bend to each breeze as it hurries by."

From a far distant period the Reed has been a symbol of "music." One of the earliest instruments of the rustic performer was made from the stalk of some Reed—the primitive flute or pipe, sometimes also called "organ." The old Greek legend connects the plant with Pan, the rural divinity, and Syrinx, who, to escape the too affectionate god, leaped into a river, and was there transformed into a Reed. The music of it became a sound of mournful reproach to Pan, but he was prompted to fashion a pipe out of the stem. Such is the legend which seems to refer to the tall *Arundo phragmites*, once much in requisition for thatching. Gerard tells us that he sought in vain for information concerning the growth of the Cypress Reed (*A. donax*), a foreign species he wished to cultivate, and which was used in Turkey to make staves carried by dignitaries, being often much ornamented. A conspicuous member of an allied family, the Reed Mace (*Typha latifolia*), which can make its 8 feet of height, has served not only as a symbol of authority but also as a rod, and Loudon states that several Italian painters have drawn this Reed in their pictures, supposing it to be the one presented to the Saviour of men. Hence its brown velvety catkins became symbols of "insult." On the Continent and elsewhere pillows are

stuffed with their down. Nearly every land exhibits this plant, which is abundant even on the swamps of New Zealand. At one time the Spitalfields weavers used the heads for brushing silk and velvet.

Placed now in a separate genus from the other Reeds, *Amphipha arundinacea*, by its straw coloured panicle of flowers crowded into a sort of spike, reminds us of "security," through the function it fulfils, which is one highly useful. This is the Sea or Mat Reed, which also has the obscure name of Marram, and by its network of creeping jointed roots forms banks along the shore, which prevent the ocean from encroaching on the land, while, by binding the sand together, it keeps that in its marginal position. Its stem is rigid, smooth, almost solid, and the involute bluish leaves are sharp pointed. A similar service is rendered mankind by some of the Lyme Grasses, which have great power in resisting the force of the sea. *Elymus arenarius* is tall, and has long leaves, but it seldom flowers on our coasts. The rarer Pendulous Lyme Grass has been grown in gardens, this is *E. geniculatus*, a slender elegant plant, with a spike sometimes 2 feet long, which takes a bend at a sharp angle after the expansion of the florets. Some of the Fescues also help to bind together sandy banks, as, for instance, *Festuca rubra*, the creeping roots of which extend for yards. Formerly people thought the shorter Fescue Grasses were excellent food for sheep. The name was suggested by the wiriness of the stem, and few Grasses stand cold better than these.

Symbolic of "skill," or, as others say, of "war," the Arrowhead with its warlike name of *Sagittaria sagittifolia* is a beautiful plant, noticeable along some English rivers. The flowers are in spikes; each blossom has three petals of brilliant white, each having a spot of purple or violet. It was, however, the leaves that suggested its name; these grow in masses, springing from the root, and are shaped like the head of an arrow. Attached to the roots are tubers, containing starch, but also acrid matter, which may be removed by washing; at one time they were believed to contain a cure for hydrophobia. Allied to this plant are the Arrow Grasses of the genus *Triglochin*; they have mostly narrow leaves and a tallish spike of green flowers. So are the Water Plantains fond of ponds and lakes. The common *Alisma plantago* has large leaves, oval, of a delicate green, with flowers of rose or lilac, the panicles being much divided; the petals are three, falling off so rapidly that the plant seldom makes a good display. Some people say this is the "plantage" mentioned by Shakespeare in the following line, "As true as steel, as plantage to the moon." Hence the plant is regarded as one of the emblems of truth. The idea seems to have been that the Water Plantain, like some other species, turned its flowers so that they should follow the course of the moon, just as the Sunflowers were supposed to move towards the sun. Perhaps it was from this notion that in popular belief the plant was much esteemed as a wound herb; no doubt it is slightly astringent. Curious is the starry-headed Water Plantain (*A. damasonium*), having its white flowers in clusters; the capsules take the form of a star.

We cannot see exactly why the flower of the Branched Bur-reed (*Sparganium ramosum*) should represent "rudeness;" the significance of the popular name is evident, for when in bloom the plant looks as if it were covered with yellow feathery balls; these are succeeded by brownish capsules, like miniature Apples. The unbranched *S. simplex* has fewer flowers, but they are larger and also more feathery. The Bulrush (*Scirpus lacustris*) is said to remind us of "indiscretion," and I presume so do its relatives, for it was to the Rushes that the unwise individual of olden time, bursting with his secret, went and whispered the fact that his king had ass's ears, and, according to the legend, was surprised to hear the plants proclaiming it to everybody who came near. This resembles rather an overgrown Grass with its brown soft spikes, being often 6 feet high. Frequently it has for its companion in the marshes the shorter *Juncus conglomeratus*, having a dense head of flowers issuing from the side of the stalk, used in the Tudor times for strewing floors, and also for candles when dipped in fat. Still shorter is the Moss Rush, oddly called Goose Corn (*J. squarrosus*), which has only a few large flowers on its panicle; it used to be very common on heaths near London. Apparently the Toad Rush (*J. bufonius*) got its name from a fancied resemblance the capsule has to the shape of a toad. But the monarch of the Rushes is the stately *Butomus umbellatus*, which has three sepals and three petals of red, also nine stamens, symbolic of "confidence in Heaven," it is said. The leaves are handsome, too; but their sharp edges, handled unwarily, will wound like a strip of thin glass.

Eastern sages and teachers, in remote ages, took the fragile flowers of the Grass tribe as an emblem of the brevity or uncertainty of human life, but, besides that, Grass generally is a representative of "usefulness." Special meanings have been attached to the flowers of some kinds. The flowers of the Foxtails in the

genus *Alopecurus* represent "cunning;" the soft species of *Holcus*, of little value, tell of "uselessness," and the handsome *Melic Grasses* suggest "elegance." Well may the Quaking Grasses, by their agitation, remind us of "restlessness" or "fussiness," but "volatility" does not seem to be so suitable a meaning for the Rye Grasses. The Holy Grass (*Hierochloa borealis*), which grows in the far North, was so named because at one period it was gathered to strew about churches on some festivals. Like the Reed, the Oat is a symbol of music, and the golden Wheat of our fields is a sign of plenty.—J. R. S. C.

APPLES.

JUDGING AT THE CRYSTAL PALACE.

IN reply to Mr. McIndoe (page 615, last vol.) I wish to say I brought forward no argument of my own (in a previous note), but simply wrote to state a fact. The R.H.S., in its schedule of the autumn fruit show held at the Crystal Palace, arranged two lists of Apples, one headed "dessert Apples" the other "cooking Apples," while under another heading in the schedule a clause is inserted for the guidance of both exhibitors and judges relating to the collections, which says, "In distinguishing dessert and cooking varieties be guided (as far as it goes) by Division 4." Under the above distinct headings Emperor Alexander Apple is placed in the latter.—C. HERRIN, *Droghmore, Maidenhead*.

[Our correspondent is quite correct. The Society evidently felt the desirability of giving precise guidance on the point, and it would be well if other societies would follow the example, as then exhibitors would know that if they infringed the *wording* of the schedule, and especially with "intention to deceive," not otherwise, they would be liable to disqualification. [Code, page 11, par 38.] With two lists of Apples only we cannot imagine many persons doing otherwise than following the example of the R.H.S. in respect of the Apple in question, and in our opinion it was placed in the right list.]

DISQUALIFYING AT SHOWS.

ALL exhibitors should be grateful for the test you have submitted for determining the question of disqualification at shows—namely, "Is any judge entitled to disqualify any exhibitor who has not infringed any rule, or ignored any condition or stipulation in the schedule that may be provided for the guidance of all." There can be little doubt regarding the answer such a question is likely to elicit—viz., a decided No! Every exhibitor is justified in availing himself of the privilege of staging anything he may choose within the rules of the schedule, and no judge has any right to disqualify an exhibit simply because it contains something out of keeping with his personal views. Is it not as much the duty of judges as of exhibitors to act strictly within the terms of the schedule?—R. C. H.

[Before closing the discussion on the York disqualification, which we think will do good, we may say (1) That a long communication has been sent to us, the result of a request by persons interested in the question, and who supplied the writer of the communication with materials and a schedule for the purpose of obtaining his views. (2) That the said writer, who is an old exhibitor, arrives at no more definite conclusion in seven hundred words than that "exhibitors must read the schedule of a show, and take their chance." (3) That no schedule has been sent to us by either of the disputants or officials. (4) That Mr. Riddell is entitled to say he is disappointed by the decision arrived at not to let the case go to arbitration before a high and impartial tribunal, willing to act from a sense of public duty.]

CLASSIFICATION OF APPLES.

AS I think I was one of the first (last year) to call attention to the necessity of the classification of Apples by some recognised authority for exhibition, I should like to have my say on the proposals put forward by Mr. Wilks.

I am sorry I must differ from him and vote for three lists, Kitchen, Table, and K.T., and this simply because things are so, and no amount of expediency or argument can alter the fact. Blenheim Pippin, for instance, is a good-looking Apple and a good dessert Apple, and to label it as not the one or the other would be, in my opinion, a mistake.

I see no reason why it and a few similar Apples should not be exhibited in both classes without confusion; but if, as seems likely, I should be in a minority, I would loyally accept the decision of the R.H.S.—W. R. RAILLEM.

I WAS pleased to read the letter in last week's Journal written by the Rev. W. Wilks on the classification of Apples for show purposes, and to find that the Royal Horticultural Society is willing to take up the question of kitchen and dessert Apples. Why not Pears also, and give us authoritative lists of each?

Mr. Wilks asks whether two definite lists are to be made, or are three wished for. As far as my opinion and experience go, I should say two only. I cannot see that a third list is at all needed. For instance, if any horticultural society wished to offer prizes for a collection of six, twelve, or twenty-four varieties of Apples, it could be so expressed in their schedule without reference to dessert or kitchen, when, of course, any variety would be admissible; but when dessert or kitchen are specified an authorised catalogue of such from the Royal would be a great assistance to exhibitors and judges.

If such a list is published, the question will arise, How is it to be put into practice? In a great measure it must remain optional with provincial societies, but I think all those in union with the Royal should be bound by its rules. Societies not in union could insert in their schedule something like the following notice:—"The R.H.S. definition of dessert and kitchen fruits will be adhered to;" and when such notice is not given judges would be glad of such an authority as the Royal to refer to in case of disputes.

These presumed lists, and the above remarks, of course do not apply in any way to private family use.—J. EASTER, *Nostell Priory Gardens*.

COOKING AND DESSERT APPLES.

I HAVE been wondering whether much of the trouble which has resulted of late, and the discussion which has grown out of that trouble, is not more the product of the improper use of arbitrary terms than of common sense requirements. Thus we find the classification of certain named Apples in the R.H.S. fruit show schedule quoted as authority in one way, and a member of the R.H.S. Council, Mr. Bunyard, writing in deprecation of that view in relation to so-called intermediate varieties. Now, in providing for named single dish classes in this schedule why are the arbitrary terms cooking and dessert used at all? If any specific variety be asked for what consequence is it whether called cooking or dessert? Only samples of the variety will be shown in its proper class, and it is entirely unimportant that any other heading than its class number and name be furnished.

The only classes of a single dish nature to which the terms may apply are those for "any other variety;" but unless these are tasted, or some other more rigid rule of judging be applied, they may for any good they are be excluded. The framers of the schedule should insert separate classes for all the known best, and the rest will, if worth anything, find representatives in the collections. Then in relation to these it will be said there must be some classification. That is so, no doubt, but it should not be of the arbitrary nature at present in existence. I greatly prefer collections "for Size and Appearance," and the same "for Flavour and Appearance." In such cases there could be no disqualifications whatever, as all the fruits would be judged according to their merits in their respective classes. But when the arbitrary terms "cooking" or "dessert" are introduced then you open the door at once to objections, that "this is not a cooking Apple" or "that is not a dessert variety," and so on, leading, as the recent discussion has shown, to endless dissension, and entirely without reason.

We have seen many inferior eating varieties hard in flesh, and comparatively flavourless, classed as dessert varieties, and admitted to such so-called collections, that really have not one tithe the beauty of appearance or soft pleasant flesh which characterises many others that have been arbitrarily excluded from "dessert" classes, simply because of the employment of arbitrary terms. Medium sized pretty fruits of Duchess of Oldenburg, Emperor Alexander, Blenheim Pippin, Cox's Pomona, Peasgood's Nonesuch, Gascoigne's Scarlet, Lady Henniker, Roundway Magnum Bonum, very large, yet one of the best flavoured Apples in cultivation; Prince Albert, Queen Caroline, just now first-rate; and many others.

I wonder how many gardeners there are, including some who have written strongly in favour of arbitrary classification, who do not send some samples of those varieties to table when they have them, and have neither Cox's, Ribstons, or King of the Pippins for use? Nay, it is possible to tire of having these excellent varieties every day. If the R.H.S. will set the example by refraining from employing henceforth arbitrary terms in relation to their Apple or Pear classes they will do much to clear the air of the existing confusion and disputation.—A. DEAN.

[This is a new idea and worthy of consideration. The question of dessert and culinary Apples is entirely one of individual fancy.]

KEEPING APPLES.

THAT every variety of Apple, chiefly according to the softness or firmness of its flesh, has its ordinary keeping period, is of course the case; but keeping properties may be aided or deteriorated by methods or places of storing. Still, kept with ever so much of care there must be certain deterioration if the varieties be kept over their natural period. I have often wondered how many of the fine looking Apples shown late in winter are really good in quality. If they be not good, there can be no merit whatever in the keeping of them so late. Then it is well worth ascertaining what methods of keeping do best, apart from appearance, to preserve quality in the flesh. That is a matter with respect to which we may well have much of experimenting. Very low temperatures will not do for Apples, although in such cases appearance may be preserved.

A very cold atmosphere does undoubtedly deteriorate flesh quality, just as a dry atmosphere shrivels and absorbs juice or moisture. If ever British growers of Apples are to compete with the winter imports of these fruits from America, they will have to discern which are not merely the cheapest, but also the most efficient means of storing to preserve flesh quality, as well as good appearance, as long as possible. It is probable that the most expensively built stores would not be by any means the best. Concrete built sheds, having walls 12 inches thick, and thatched heavily with straw, especially if erected beneath trees, would probably not only exclude all frost, but keep a very equable temperature within. If, too, the floor be the soil only, the shelves made of open trellises with the rough edges planed off, and changes of air occasionally permitted, the very best results would be obtained.—A. K.

WINTER PRUNING.

(Continued from page 603 last vol.)

WALL TREES.—Apple trees are not often grown against walls. In the northern parts of the kingdom trees are frequently, as compared with the southern districts, found against walls in old-fashioned gardens, and such trees, for beauty of training, as are only equalled by the similar examples in Pear trees. The finest Apples I have ever seen were grown on a tree against a stone wall 590 feet above sea level, and within a quarter of a mile from the coast on a south aspect. It was the little known Scotch variety named Melrose from having been introduced from the Continent by the monks of Melrose Abbey. On grafting it on Paradise stocks I found the trees bear grand fruit in the third year, $3\frac{1}{2}$ inches to 4 inches wide and 3 inches to $3\frac{1}{2}$ inches high, highly coloured on the sun side. The fruit was of excellent quality, sweet and pleasantly subacid, suitable for culinary or dessert purposes, and in use from October to January. Unfortunately, the trees were very much attacked by canker fungus (*Nectria ditissima*), the spores, or rather their germinal tubes, not entering by a wound, but by piercing right through the bark on a smooth part.

The American Apples, as a rule, do well against walls, quite rivalling the finest imported examples, there being many walls that might be profitably occupied with Apple trees, fine specimen fruit fetching 2s. to 3s. per dozen. Fan-training is the best, as when a limb goes off or gets too long in the spurs it is easy to train a growth in from the base, which will commence bearing in the third year. Nothing is simpler than training-in shoots so that when they have grown a yard they will be 1 foot apart, the leading growths being taken forward and side growths stopped at the third good leaf, not counting the small basal ones. This can be done about the middle of July, and spurs will form at the base. While the tree is extending all goes well, as there is a reciprocal action between the roots and branches; but when the limit of the space is reached spray is made in response to the summer pinching and the removal of growths in the winter, and then it is a question of leaves instead of fruit.

If the spurs are kept thin from the first, so that light and air has access to the foliage, the cropping may be such as to counteract the tendency to growth beyond that necessary for continued fertility; but if the tree ever become crowded with spray that cannot be restrained by summer pruning, either root-pruning must be resorted to and the spurs well thinned, or the limbs cut boldly back and the training recommenced. The sudden check appears as salutary as in re-grafting, the growth not being excessive, though the roots are not interfered with. Thinning the spurs has some effect, but whether from the trees having more leaves than a cut-back, the results are not as satisfactory. Nevertheless, no tree can bear with the spurs overspread by a thicket of spray; therefore thin the spurs, cut away the strong wood growths, and keep as near the wall as possible the stubby shoots, so as to get short stout spurs.

Apple trees against walls sometimes become infested with mussel scale. There is nothing better than a caustic soda and pearlash wash, 1 oz. each to a gallon of water, dissolving each separately in a small quantity of hot water, then adding the two together, and the remainder of the water hot, using with a brush at a temperature of 120° to 130° , taking care to reach all round the branches and stem. It suffices if the whole be well moistened without running down the bark to the roots, which must be avoided. Boiled linseed oil is an old-fashioned and good remedy, but must be put on as soon as the leaves fall, as the eggs are not sufficiently developed to escape death with the parent. Similar remarks apply to petroleum, neither oil being of any use after the parent scale has ceased existence, and left her eggs safely in a sort of down resisting the oils. Of the two, boiled linseed oil is more efficacious, but the caustic soda (hardening) and pearlash (softening) wash is better than either.

APRICOTS.—This fruit is going out of fashion, even with cottagers who formerly had trees on their cottages which sometimes paid the rents. Plums and Pears that bring next to nothing have supplanted the delicious Apricot trees. This is a pity, for the imported Apricots are not nearly as fine as British wall fruit. The trees are very accommodating; all that is necessary is to cover the wall space with growths so that the leaves have light and air playing between them, the side growths being shortened to about three leaves of their base, and the spurs at the winter pruning being shortened so as to keep plenty of stubby and promising ones near the wall. Old and bare shoots or branches are also cut out, along with dead spurs, young growths taking their place. Nothing could be easier than training Apricot trees, as when young growths are laid in they are sure to form spurs and bear fruit abundantly. That is the whole art—an even spread of bearing wood all over the space, and not cramping the trees for space. Cottage and farmhouse fronts, facing south, are far better than garden walls for Apricots, as the projecting roofs secure a drier atmosphere and some protection at blossoming time, but the space is the thing—plenty of height and breadth.

On a house wall 24 by 24 feet 1500 Apricots a year have been gathered for a generation, and a man about four days a year does all the work that has to be paid for. The trees are Moorpark, or rather the variety Hemskirk, and neither gum nor the branches die off. The soil is a light loam of the new red sandstone formation, is practically an alluvial silt left dry by the receding water. The only insects bothering the grower are the caterpillars of the Apricot moth (*Tortrix angustiorana*), and these are got rid of by pinching the rolled leaves between the finger and thumb. When the red appears on the buds and the white

just peeping on the forwardest is the usual time for pruning Apricot trees, but it is better done in the early autumn by a practised hand, as the wounds heal better, and the buds can be told with precision.

CHERRIES.—Everybody likes Cherries. They, like Apricots, do better on high than low walls, and are more obliging in the matter of aspect. There is the large glossy black Early Rivers and the equally large shiny waxen yellow with a glowing cheek, Governor Wood, for south aspects; May Duke and many others for east, and Morello for northern outlooks. They bear grandly, and do well on all but wet clayey soils. Fan training is the best for them, as the space can be covered evenly with branches at about 1 foot apart, and beyond stopping the summer growths to about three leaves, not counting the basal leaves, cutting these back to an inch of their base early in autumn, and training the leading shoots in their full length, are very little trouble. Morello bears on both the young wood of last year and on spurs, therefore it is a question of cutting out old worn out wood and laying in young. This has to be provided for at summer trimming, but it is a great mistake not to make provision for fruit on spurs by pinching any shoots that there is not room for laying in, and will not cause overcrowding, to about three leaves, counting the basal ones in this case, for though every bud formed may give a cluster of Cherries, these will not drop like Peaches or Nectarines for want of growths above them.

The great pest of Cherry trees on walls is black aphid (*Aphis cerasi*). How this creature hibernates over the winter I could never make out satisfactorily. Sometimes eggs are laid on the spurs at the base of the buds, and hatch out after the trees have got fairly into leaf, and at once fasten on the tender points of the shoots and young leaves, causing the latter to form shelters for them against the weather. In other cases there are no eggs on the buds or just below them, yet the points of the shoots become infested all the same, and never a winged one have I come across at this early stage. That there has been one is unquestionable, but whence it came I could not make out very clearly, though finding the species on various herbaceous plants. Can any of your correspondents throw any light on this point? The flies always migrated even from wild Cherries to herbaceous plants when the growths become too hard for sucking.

On Morello and trees under glass the parthenogenetic generations go on indefinitely, but in the case of the Morello a hard winter causes a lull, and the infection recurs late. It is this late brood that I should like to get at, but could never make out clearly that they came in winged form from other infested trees, wild or cultivated, nor fix upon the exact herbaceous plant for the earlier winged form.

Besides the aphid caterpillars of the cloak moths (*Spilonota* species) attack the young growths, and even the young Cherries. No winter dressing appears much use against either aphides or the caterpillars, still there is no harm in using a composition that will kill what there then be on the trees, and make them distasteful to any coming after. The caustic soda and pearlash wash is cleanly and effective, but must be used somewhat weaker on stone fruit trees.

FIGS.—This fruit has gained favour. It does well on buildings with projecting roofs, and must have a south aspect. Brunswick, Brown Turkey, and White Marseilles are the best varieties, as without size and good quality it is useless striving to catch the public eye. Firm calcareous gravels suit Figs. The question, then, is to secure stout short-jointed wood by having the branches sufficiently far apart, and to keep up a succession of bearing wood from base to extremity. Winter pruning is best done as soon as the leaves fall, cutting away the bare and reserving the young growths evenly all over the space. Protection may be adopted where circumstances admit, and is a good old plan. It, however, is only needed in very severe winters, and probably does more good by preventing sudden thawing after severe frost than anything else.—G. ABBEY.

(To be continued.)

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE first annual meeting of the Worcester and District Auxiliary of the Gardeners' Royal Benevolent Institution was held some days ago at the Guildhall. Mr. R. C. Smith Carrington was in the chair, and there were also present Messrs. Crump, J. W. Sedgley, G. Griffin, W. Child, D. Cowan, A. Young, W. S. Harlstone, E. Blackwell, J. W. Horsman, H. Russell, J. Williams, J. Justice, G. Mason, H. Whittington, F. Styles, C. Crookes, and J. H. White (Hon. Sec. and Treasurer). Apologies for absence were received from Mr. Alfred Baldwin, M.P., and several gardeners.

The balance sheet for the year showed that the receipts were £175 9s. 6d., and the expenditure £172 5s. (£164 15s. of which has been sent to headquarters in London), leaving a balance in hand of £3 4s. 6d. The Committee in its report expressed its sincere thanks to those who had given such handsome donations to the branch, and especially to Earl Beauchamp for so kindly allowing his gardens to be thrown open for the benefit of its funds. It reported that there were already nine new subscribers to the auxiliary, and that Mr. John Corbett had promised to treble his subscription, and Messrs. Smith and Co. had also increased their subscription to £2 2s. The Committee, on behalf of Mr. David Davis, desired to express his thanks to all those who supported him at the last election, and trusted by their votes at the forthcoming election to carry his case. The Committee urged upon all the necessity of joining the Institution. The report and balance sheet were adopted, on the proposition of Mr. Harlstone, seconded by Mr. Russell.

The Secretary read a letter he had received from the head office saying that the Committee desired to place on record its hearty appreciation of the services rendered to that Institution by Mr. J. H. White as Hon. Secretary and Treasurer of the Worcester and District Auxiliary, and beg to tender sincere thanks for his kind and successful efforts on behalf of the charity. On the proposition of Mr. Crump, seconded by Mr. Hurlstone, Earl Beauchamp was re-elected President; and on the proposition of the Chairman, seconded by Mr. Child, the Mayor (Mr. C. W. Dyson Perrins) was elected Chairman of the Executive Committee. The following were elected on the Executive Committee:—Messrs. Crump, Child, Cowan, Hurlstone, Mason, Russell, and Young.

The Chairman, in proposing the re-election of Mr. White, said that the branch was to be congratulated upon having such an excellent officer. The success to which the head office had testified had been due solely to Mr. White's exertions. Mr. Child seconded, and the proposition was carried; Mr. White briefly responding. Subscriptions were announced from several new members. Mr. Young called attention to the fact that many gardeners in the district were members of the Institution, but not of the auxiliary, and suggested that some steps should be taken to bring them into it, but nothing was decided upon.—("Worcester Daily Times.")

PEAR MARIE BENOIST.

THOSE who have grown Marie Benoist Pear (fig. 6) esteem it as a variety of considerable merit. It is a very valuable addition to late Pears, worthy of cultivation, and the tree grows well and bears freely. The fruit is large, irregularly turbinate, and more swollen on one side than on the other. Skin bright green, dotted and lined with russet, and covered with patches of fawn-coloured russet. Eye small, open, and deeply set. Stalk very short and thick, obliquely inserted, with a large swelling on one side of it. Flesh white, tender, very melting, and slightly gritty, very juicy, sweet, and delicately perfumed. An excellent dessert Pear, ripe during January and February. A medium-sized fruit is represented. This was raised by M. Auguste Benoist, a nurseryman at Brissac, not far from Angers, and named after his daughter Marie.

ROCHFORD HOUSE.

ROCHFORD HOUSE, the residence of Mrs. Williams, is most pleasantly situated in the midst of park-like scenery on a gentle eminence, two miles E.S.E. of Tenbury, in the extreme western part of Worcestershire. The ancient town of Tenbury is picturesquely located in the valley of the Teme. It is surrounded by charming scenery, valleys and hills richly clothed with Hop plantations, fertile orchards, verdant meadows, and smiling corn fields. Though a fact not well known, but found by the old historians, Tenbury is celebrated as the birthplace and favourite residence of the noble Caractacus, which circumstance will lend a double charm to a place so rich in Nature's gifts.

The walk from Tenbury to Rochford is amidst some of Nature's most beautiful pictures; deep ravines and rising ground, the latter commanding extensive views of the distant hills. It is not on account of its extensive ranges of glass houses or its broad acres of pleasure grounds that we wish to bring the place into prominence, but the superb hardy fruit that is so successfully cultivated year after year.

We had the pleasure of visiting these gardens during the Plum harvest, towards the end of August, and then again about the middle of December, 1896. On entering the pleasure grounds we are at once surrounded with fine evergreens and charming flower beds, furnished for the winter with dwarf shrubs and hardy spring-flowering plants, including Forget-me-nots, Wallflowers, Daisies, Pansies, Polyanthus, Auriculas, and the usual run of hardy bulbs. We noticed some handsome Conifers, remarkable for their beauty and symmetry of contour, such as Cedars of the Deodara type, also *C. Libani*, *C. atlantica*, *Thuja Lobbi*, *T. elegantissima*, and fine Cupressuses.

In the adjoining greenhouse the Chrysanthemums were nearly over, but the remnant that was left showed plainly that the flowers had been of no mean order. Roman Hyacinths were just bursting into flower, and we also saw fine Primulas, Cyclamens, and Callas. In the stove, separated from the greenhouse by a glass partition, there were the usual plants which are generally found in these structures.

We now pass beneath the shade of tall trees, and enter the kitchen garden; it is about 1½ acre in extent, surrounded by well-built brick walls, a border about 10 feet wide skirting the walls, and the centre laid out in six squares. Many of the squares are separated from the walks by a broad bordering of the Mossy Saxifrage (*S. hypnoides*), which during its season of bloom gives the garden a bright and cheerful appearance. On the south side was the Peach range, well furnished with fruitful trees, including Barrington, Old Noblesse, Crimson Galande, Walburton Admirable, Dr. Hogg, and Elrage Nectarine. On an open wall with a south aspect there were fine Apricots, such as Large Early and Moorpark; and of Peaches Rivers' Early, Sea Eagle, and Golden Eagle. On the north wall we noticed good and well-trained Cherries of the Morello section; and such Plums as Early Prolific, Victoria, Golden Drop, and The Czar. The west wall was devoted to Pears, and

included Citron des Carmes, Pitmaston Duchess, and Williams' Bon Chrétien.

It was, however, the pyramid Pear trees round the garden walks that were the objects of the greatest interest. They are from 8 to 12 feet high, and fine specimens of skilful culture. We saw the trees at the end of August, when they were laden with fine fruit, and then again in December, when every branch was smothered with fruit buds. The remains of the fruit left in the fruit-room bore ample testimony to the excellent crops that had been gathered. Mr. Paintin, the gardener, is renowned as a fruit grower of the first order. At the autumn shows at Birmingham, Hereford, and Leominster he is always considered a formidable opponent, and generally carries away the leading prizes.

The most popular sorts of Pears were Doyenné d'Été, Doyenné Boussoch, one of the best Pears in the garden; Beurré de Capiaumont, Brown Beurré, Maréchal de Cour, Louise Bonne of Jersey, Marie Louise, Marie Louise d'Uccle, a fine late Pear of good quality; Doyenné

FIG. 6.—PEAR MARIE BENOIST.

Defays, Beurré Diel, Pitmaston Duchess, Gen. Todleben, another good late Pear of high quality; Beurré Lambard, good late variety; Glou Morceau, late; Prévost, one of the best December Pears; Bergamot d'Esperen, and Zéphirin Grégoire. Standard Pears included Marie Benoist, Passe Colmar, Gratioli of Jersey, Beurré d'Amanlis, Beurré Bachelier, Uvedale's St. Germain, Vicar of Winkfield, and Catillac. The last three named are specially good as standards, but are even finer on the wall.

There was also a fine collection of Apples; indeed, there are very few places in the county where there is a better collection, or even better grown, a few as bushes; but the generality as standards. As bushes we noticed Irish Peach, Worcester Pearmain, Red Astrachan, Kerry Pippin, King of the Pippins, Court Pendu Plat; and as standards Bramley's Seedling, Beauty of Kent, Newton Wonder, Flanders Pippin, Charles' Pearmain, Devonshire Quarrenden, New Hawthornden, Minshall Crab and Winter Queening. The collection of Plums was also equal to the Apples and Pears, and contained the best and leading sorts. In the kitchen garden there were good squares of Gooseberries and Currants, and well managed plantations of Strawberries. On a south border the first pickings of Scarlet Queen are ready in May.

On the outside of the kitchen garden is the nursery, where forest trees are propagated and prepared for planting in the various plantations on the different farms, and stocks for fruit trees are also raised and in due time grafted with the best and leading sorts only. Such Apples as are only second rate are headed down and grafted with the best sorts known. Amongst these were Prince Albert, Golden Noble, Lord

Grosvenor, Newton Wonder, Nonesuch, and Bismarck. On the nursery wall there was a fine arrangement of Pears, all trained horizontally, and each year carry good crops of fruit. The sorts include many of those named above. A little distance from the gardens and adjoining the Plum orchard was a vinery 45 feet long, and containing twenty Vines of the leading sorts. The Vines, like all the other fruit-bearing trees, were in excellent order, and bore traces of skilful cultivation.

Although the gardens at Rochford House are not so extensive as some others that we have visited in the county, yet they afforded us a vast amount of pleasure and instruction. We cannot close these brief notes without expressing our deep obligation to Mr. Paintin, and the gratification our short visit yielded us.—QUINTIN READ, *Ev-sh'm*.

LUCULIA GRATISSIMA.

How is it this charming plant is not more generally grown? For covering bare walls in cool greenhouses or conservatories it has no equal. Many people, however, make a mistake in attempting to grow it in too high a temperature.

In the gardens of the Rev. H. G. Jebb, Firbeck Hall, Rotherham, there is a fine plant at present in bloom, which for the number and the size of its trusses I have not seen surpassed. Mr. Egglestone, the gardener, informed me on the day of my visit that there were upwards of 500 heads of bloom fully expanded. A medium-sized truss that I have now before me has sixty-four of its sweetly scented, pale pink flowers fully open. Blooming as it does at this dull season makes it doubly welcome, and is justly appreciated by all who have had the privilege of seeing it.

The Firbeck specimen is planted out in the conservatory in one corner of the centre bed, and is being trained over part of the roof, a position that suits it admirably, forming quite a canopy of flowers overhead. This plant should be more generally grown, as it is of easy culture.—S

HORTICULTURAL EXHIBITORS AND RAILWAY FARES.

AN erroneous impression seems to exist as to the privileges granted to exhibitors here in Ireland. The statement made by "M. W." is quoted again in last week's Journal by "T. H., Bristol." As an exhibitor I have been making inquiry into this matter, and with one exception the railway companies having termini in Dublin do not give any facility whatever to exhibitors. I am well acquainted with exhibitors attending the shows of the Royal Horticultural Society of Ireland, and they inform me that they never yet got such a privilege as stated by "M. W." The exception referred to is the Great Northern Railway, between Dublin and Belfast.

Exhibitors from Dublin and further south at the late Chrysanthemum show in Belfast, on sending in their entries to the Secretary received in return a signed railway voucher, which on being presented at the railway ticket office and paying single fare a ticket was obtained for the double journey. Show boxes were all carried free. Compare this generous treatment with that of the Dublin, Wicklow, and Wexford Railway, where a friend and I in our journey to Belfast had to travel four miles over their system, and in addition to paying full fare were also charged 1s. each for the single journey for carriage of our boxes. Railway travelling in Ireland is a more expensive luxury than in either England or Scotland, and the agitation for cheaper rates for exhibitors is just as necessary here as in other places.—J. H. CUMMING, *St. Helens Gardens, Booterstown, Dublin*.

WINTER FLOWERS AT HINDLIP HALL.

THE demand for cut flowers and decorative plants for winter work at Hindlip Hall, Worcester, is great, but Mr. H. Russell, the gardener in chief, is equal for the occasion. It was a dull cold miserable wet day when I recently visited this well-kept place, but I forgot all about the weather when I was going through the houses, for an imposing display of winter flowers met the eye everywhere.

A house is devoted to the culture of tree Carnations, producing dozens of flowers, of which Winter Cheer seemed to be a favourite, and deservedly so, for it is one of the best scarlets for winter work as seen here, plants in 32-pots producing fine crops of flowers. Many other varieties are grown, including the Malmaison section, which promises well, and a succession of flowers will be forthcoming for a long time. There is a house of Cyclamens containing about 300 well-grown plants in 6-inch pots, many of which have fully four dozen expanded flowers and an innumerable quantity of buds thrown well above the beautifully marbled foliage. Sutton's Butterfly, one of the very best whites, is in strong evidence, likewise all the varieties of Sutton's Gigantic strain.

Poinsettias are remarkably well grown. The plants were dwarf, about 15 inches high, and well clothed with foliage to the pots (5-inch). The bright scarlet bracts measure fully 18 inches across, and are superb for decoration work. A house of Bouvardias in 6-inch pots, fully 2½ to 3 feet through, are invaluable for cutting from, and I was very pleased to see a fine collection of yellow Wallflowers in pots, flowering as profusely as one could wish; the variety is Sutton's Earliest of All. These were lifted from the open ground in October, and they have the appearance of flowering for at least a month to come. The habit is dwarf and compact; the plants referred to are about a foot high,

rendering the variety worthy the attention of those wanting sweet-scented flowers during the winter months for decorative purposes. Chrysanthemums, of which all the leading varieties are grown for decorative work; although somewhat late in the season, many still remain that would do credit to any exhibition. Houses are devoted also to decorative foliage plants; all the leading Palms, Dracænas, Crotons, and Ferns are grown in great quantities and various sizes. The Crotons and Dracænas are beautifully coloured.

In the fruit houses I noticed fine crops of Grapes yet remaining, fit to adorn the table of the most fastidious. Muscat of Alexandria, fine in colour, plump in berry, and good bunches; Lady Downe's, both white and black, the former not often seen, it is grand here, and a good flavour; and other varieties equally well done. The early Peach house and vineries have been started, and look promising. If cleanliness and good order can assist the future prospects, it is in strong evidence in this well-kept place, the credit of which is due to Mr. H. Russell, who has had charge here now some few years, and whose work proclaims for him the title of a well-skilled and enthusiastic gardener.—URBANUS.

A TRIP TO THE DISMAL SWAMP.

THE large tract of inundated lowland in south-eastern Virginia known as the Dismal Swamp possesses an interest to workers in all branches of science from the fact that it is the first or most northern great series of coastal swamps extending from Norfolk southward for many miles. To the botanist such an area furnishes valuable opportunities for the study of geographical distribution and of habitat, and mainly with this object in view I made the expedition to the swamp last May in company with a geologist and two ornithologists. The accompanying notes on the flora of the region are the outcome of only two days' sojourn in the swamp itself.

In many parts of the area under consideration the term "dismal" is a misnomer, as the trees are not of sufficient size and density to exclude the sunlight altogether, or even to give that appearance of gloom afforded by the coniferous forests of the north. In the interior, however, especially around Lake Drummond, certain trees, such as *Acer rubrum* and *Nyssa biflora*, attain a very great height. The majority of the remaining trees, like *Magnolia glauca* and *Quercus nigra*, do not exceed, for the most part, 20 or 30 feet. The last two species, in company with several Ericaceous shrubs and the Hollies, *Ilex glabra* and *I. opaca*, when intertwined with the numerous woody vines that abound in the swamp, constitute an impenetrable jungle which defies even superficial investigation unless exploring botanists are armed with bush knives.

While paddling up the Jericho Canal from Suffolk in a dug-out we noted several well-marked areas in which some one of these dominant species seemed to flourish at the expense of the others. Along the side of the canal for the first few miles soil thrown out in the construction of the ditch forms a moderately firm bank, along which is a good towpath. Here the Cane grows rather sparsely, but there are numerous trees apparently not found in the interior, notably *Aralia spinosa*, *Sassafras*, *Rhus copallina*, and several Oaks. A few introduced weeds, including the ubiquitous English Daisy, are scattered along the bank.

A few miles farther we notice a gradual subsidence of the embankment, the soil becomes more moist, and the Cane grows in dense brakes, overarched the canal and effectively smothering the smaller herbaceous vegetation. Soon the water of the surrounding swamp is seen to merge with that of the ditch, and the Cane, finding no anchorage for its tough, ligneous root-stocks, disappears almost completely, its place being taken by masses of *Woodwardia*, which grow in from 1 to 2 feet of water, and whose fronds attain enormous dimensions. Around the roots of shrubs a quantity of *Sphagnum* lodges, mingled with decaying sticks and herbage, thus affording conditions favourable to the growth of such plants as *Pogonia ophioglossoides*, *Limnium tuberosum*, *Mitchella repens*, *Impatiens*, and even *Gaultheria procumbens*, the flavour of the winterberries borne by the latter being fully equal to that of specimens from a mountain woodland farther north.

As one nears the end of the canal, shrubs and trees become thicker, and the Cane is again abundant. *Similax laurifolia* and *S. rotundifolia* festoon the lower branches of the trees, while the Supplejack, *Berchemia*, the Fox Grape and the Cross Vine, *Bignonia capreolata*, strive for the possession of the lofty trunks. Fallen logs float on the surface of the water and become converted into veritable moss gardens, among which *Polypodium polypodioides* thrives.

The Bald Cypress, *Taxodium distichum*, is apparently less abundant in the swamp than formerly, and of the specimens observed by our party the majority were young. Lake Drummond is full of Cypress-stumps, indicating that a large number of these trees once grew within its area. The peculiarity exhibited by this species of forming enlarged butts, or elbows, often in connected series, is observable to less extent in most of the arborescent vegetation. The knees attain greater proportions in the Cypress, however, and seem to be designed to obviate rapid decay and to anchor the plant firmly in the depth of water that it prefers.

Lake Drummond, a sheet several miles in diameter, is the centering point of the various canals and ditches penetrating the swamp. Apparently its waters nowhere exceed 10 feet in depth, except during the period of overflow in the spring. Around its margins lie, perhaps, the most densely wooded portions of the swamp, and innumerable stumps and tree-trunks, still standing erect in the water, tell the tale of a forest that once covered much of the present surface of the lake.

Several interesting additions to the flora of the Dismal Swamp have been detected of late. Dr. Britton and Mr. Hollick found *Andromeda nitida* during an autumn trip to the swamp several years ago. Within the last two seasons Dr. A. K. Fisher has collected *Ilex lucida*, and I have found *Clematis crispa* in considerable quantity. It is very certain that a well-equipped botanical expedition would find much of interest in the still unexplored parts of this peculiar region.—CHARLES L. POLLARD (in "Garden and Forest.")

THE YOUNG GARDENERS' DOMAIN.

A GOOD BEGINNING.

DEAR "Old Boy," your appeal in the "Young Gardeners' Domain" shall not be in vain. In respect to the Gardeners' Royal Benevolent Institution I do not know the details; perhaps the Editor will kindly supply them. Come on, my comrades of fire-shovel and water-can. Let us rally round our old friend, and show him that we do practically appreciate the interest he has taken in our welfare. Perhaps it is only a start, so if it is within the limits of a journeyman's means I shall be pleased to be a member.—G. R. B.

[The heading is ours. Mr. G. J. Ingram, Secretary of the R.G.B.I., 50, Parliament Street, Westminster, will send the peroration to our correspondent by post.]

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

It is to be hoped many gardeners both young and old will be induced by the kind remarks of "An Old Boy" to become members or subscribers to this noble Institution. Every gardener in the United Kingdom ought to have his name on its rolls to further its benevolent object—the relief of those in distress, or, if incapacitated from work after reaching the age of sixty, if they comply with the rules, or younger men in cases of total disability, are eligible for pensions. It is with pleasure I inform our friend that I have during this last year been enabled to make myself a life member of the Institution, and still hope to be able to do some good in furthering its claims for financial support; likewise the sister Institution—the Royal Gardeners' Orphan Fund, of which I hope to become also a life member. I have for some time been a subscriber, "if indirectly." I conclude by wishing "An Old Boy" a happy and prosperous new year. He has for some time been contributing to my weekly happiness, and I am looking for more.—J. S. G.

[Our correspondent, who is an under gardener, is to be congratulated on his thoughtfulness, thrift, and prudence. He has the privilege of serving under one of Nature's noblemen, whose good example has been followed.]

CALANTHES.

WHERE there is a demand for cut flowers at Christmas I know of nothing more valuable than the following varieties of *Calanthes*—viz., *Veitchi*, *vestita alba* and *rubra*. They should be shaken out of the old soil every season, and repotted during the month of March in the ordinary way, and not elevated above the rim, in a compost of two parts loam, one part peat, and one part leaf mould, adding a little dried cow manure and a dash of sharp sand. Three bulbs may be grown in a 6-inch pot or one in a 4-inch. When potted they may be placed on a shelf near the glass in a temperature of 60° to 65°. They will need very careful watering for some time after they are potted. When the pots become full of roots weak liquid manure water is essential. These plants lose most of their foliage by the time they flower, which causes rather an unsightly appearance. To obviate this they may be arranged among other foliage plants, or small Ferns (sporelings) should be pricked in between the pseudo-bulbs, which will be a great relief to the bare stems.—AN ENGLISHMAN IN SCOTLAND.

[Little and good; only one small correction needed.]

MALMAISON CARNATIONS.

I THINK "J. F. D.'s" suggestion (page 594) re "Winter Flowering Plants," a very good one. One plant I would like to bring to notice for a winter flowering one is the noble Malmaison Carnation. At what season of the year is such a flower more appreciated, coming in at Osberton just before Christmas, a batch of 400, in 10-inch pots, eight to ten blooms on a plant? Not only as a winter flowering plant would I refer to this, but also as one capable of being flowered twice in one year, as all these plants were flowered in the months of June and July last. I may also say this has all been attained under a treatment put down as fatal by some growers. I mean the syringing of the plants, a treatment Mr. Crisp advocates strongly, and there is no doubt about their liking it. There is no sign of disease, and the dark healthy broad foliage hangs over the rim of the pot. The plants are 2 feet high, and about 2 feet across. Anyone doubting the syringing system cannot do better than "come and see," as our worthy friend, Mr. Cannell of Swanley, would say.—A. C. W., *Osberton Gardens*.

[A few other excellent articles are crowded out, but they will lose nothing by keeping.]

R.H.S. EXAMINATION.

WITH your kind permission, Mr. Editor, I would like to offer one or two remarks on the above subject. I will say at the commencement that I quite approve of examinations, at the same time agree with the

remarks of "Young Gardener" on the subject. Having been a candidate at the last exam I always read anything connected with it with very deep interest. Especially so did I read the short note by "A. D." (p. 155) in which he speaks of a railway porter who passed an excellent exam. To Mr. Walker (for that is his name) "all honour is due." Strange to say, this gentleman stood before me in the exam.

I must confess I feel utterly ashamed of myself, having spent sixteen years in well-managed gardens under some of the best gardeners in the country. I must have made bad use of my time. I have held my present position as second in a garden of large dimensions for more than four years, having twenty-five glass houses more or less under my charge, containing a varied collection of fruits and plants in general cultivation. I only managed to reach the "third class."

I must say again, as I have said before, that these examinations are not a fair test of a gardener's ability. It may be from the scientific point of view, which many young men in out-of-the-way gardens can only rarely get by self-study. It must be admitted that it takes a great deal of practice to make the scientist "perfect." Any sensible person knows what a few months cramming or coaching will do, though it requires many years of work to become "practical," without which no man in a garden of any extent can acquire the knowledge of the many and varied duties to be performed for the successful management of the several departments.

It is utterly impossible to obtain the desired results in the high-class cultivation of fruits, flowers, and vegetables without diligence, care, and thought, combined with the most important point—"practice." This must be very plain to see when we consider what gardening was and is to-day. The great improvements brought about each year by experience—I am speaking from personal experience—that each year's practice gives additional confidence in the operations which only occur perhaps once in the year.

It has been remarked that many leading pillars of horticulture at the present day have spent a great portion of their lives at other occupations. I would ask, Are these men now thoroughly practical? I admit it is wise and prudent to be well equipped—possessing a first-class certificate if possible, but more easily, and perhaps more certainly, a second or third. These latter may be and are won by many, who of course, it is understood, are in no way qualified to take up the position of head gardener.

It seems strange so few young gardeners enter these exams from the northern parts of the kingdom. "There must be a reason." What is it?—SUBORDINATE.

[Our correspondent writes very well, and no doubt works very well. Perhaps he was nervous in the exam. "Science is a bright light that guides the way, but the path itself is practice."]

THE following questions, with answers appended, are written to give young gardeners and students of horticulture some idea of what the R.H.S. examination is like. The time each question took to answer is given at the end of each answer. I shall take eight questions from the paper set last year by the R.H.S., not in the order in which they come, but the easier to answer by the writer taken first, leaving the more difficult ones till later.

Question 3.—"Of the elements and compounds that go to make up the constitution of plants, a few occur in much larger proportions than others. Which are they, and whence are they obtained?"

The elements and compounds that go to make up the constitution of plants, and which occur in the largest proportions, are as follows:—Elements—Carbon, oxygen, and nitrogen. Compounds—Potash, phosphoric acid, and lime. The carbon and part of the oxygen are obtained from the carbonic acid gas in the atmosphere, while the remaining oxygen, together with the nitrogen, potash, phosphoric acid, and lime are taken from the soil. Time, six minutes.

Question 1.—"What are the objects sought to be obtained by digging the soil? Of what use is it to crops?"

The objects sought for in digging soils are as follows:—1, To loosen and break them, so as to allow water and air to penetrate more readily. 2, To bring the soil into a finer state of division by exposing fresh surfaces to the action of air, water, frost, &c.; and 3, To bury weeds, or to mix manure with the soil.

Its use to crops is:—1, To enable the roots to penetrate the soil more readily in search of food, and also to allow oxygen to reach them (the roots), without which they could not live. 2, To enable the carbonic acid and oxygen gases from the atmosphere to attack the inert plant food in the soil, and make it more available for crops. Time, twelve minutes.

Question 4.—"What are the 'reserve materials' of plants? Where are they stored? What use is made of them?"

(a), The reserve materials of plants are those portions of organised or constructed food substances which are stored up in some parts of the plant for its future use. They consist of the following:—(1) carbohydrates, (2) fats, (3) proteids, (4) amides.

(b), The carbohydrates are found in a variety of forms, (1) as starch in some seeds and tubers; (2) as cellulose in the thickened portion of some cell walls—e.g., the Date seed; (3) as Grape sugar in some fruits—e.g., Grape Vine; (4) as cane sugar in some roots and stems—e.g., sugar beet, and sugar cane; (5) as inulin in some roots—e.g., Dahlia roots.

The fats are found in many seeds (e.g., Flax, Cocoa-nut, &c.), and also in the cells of many plants.

The proteids are found in a variety of forms in all seeds, and in tubers, bulbs, and all parts of plants.

The amides are present in some seeds, and in the cells of many plants.

(c), The reserve materials are of use to seeds and plants, to supply them with the substances necessary to build up their growth until they have leaves expanded, when they are able to construct new food from the raw materials which are derived from the soil and air. Time, thirty minutes.

Question 9.—“What are the main differences between the ‘seed’ of a flowering plant and the ‘spore’ of a fungus?”

A seed consists of several parts. On the outside there is a skin (testa) to protect the embryonic plant within. The tiny plantlet consists of a primary root (radicle), a primary stem (plumule), one or more seed leaves (cotyledons), and sometimes a store of food. The seed is therefore in all respects a miniature plant. The spore of a fungus is like a seed—a reproductive body—but it differs from a seed of a flowering plant, because it does not contain any embryo or rudimentary plant. Time, twenty minutes.—A STUDENT.

(To be continued.)

[Lest it should be thought our correspondent is merely a book hunter, it may be said that he is a most industrious worker. We have had the pleasure of a handshake with the young gardener, and found it hard by honourable toil. He is neither afraid of fork, spade, nor barrow, and we suspect is destined to make his way in the world if health do not fail him.]

FRUIT FORCING.

Cherry House.—When the trees in the house closed in December are fairly on the move, let the day temperature be kept at 50° to 55°, and if the days are bright air should be admitted, but only to the extent of keeping it from rising above 65°, commencing to ventilate at 50°, increasing it at 55°, above which a free circulation of air must be allowed, and when the temperature declines to 55° close the house for the day. The night temperature should still be kept at 40° to 45° artificially. Syringe the trees in the morning and early afternoon on bright days, but if the weather be dull it will suffice if the borders and other surfaces are damped whenever they become dry. Examine the borders, supplying water if necessary, moistening them thoroughly, the water not being less in temperature than that of the house. Trees in pots must be well supplied with water, repeating the supplies as necessary to insure thorough moisture in the soil.

Cucumbers.—The sun and the mild weather at the close of last year have helped winter fruiterers wonderfully, a little ventilation in the early part of the day when the weather was mild aiding by evaporation to solidify the growth, and closing early in the afternoon or shortly after midday, with damping the house at that time, insuring steady progressive development in growth of plant and fruit. On fine mornings the floors should be damped and the plants lightly syringed, which discourages red spider, and to some extent holds the pests in check. Weak liquid manure may be given to plants in free growth, but should the plants not show signs of growing freely sprinkle a little—about a good handful—of a mixture of dissolved bones and soot in equal parts on the bed, and water moderately with tepid water only until the growth becomes free. To encourage surface roots a top-dressing should be given of turfy loam, from the size of a pea to an egg, adding a fourth of sweetened horse droppings, having it previously warmed to the temperature of the house. Maintain the night temperature at 65°, a few degrees less in severe and a few degrees more in mild weather, 70° to 75° by day, and 80° to 85° or 90° with sun heat, keeping the bottom heat steady at 80°.

Plants for the early supply of fruit where winter Cucumbers are not grown should now be prepared, sowing the seeds singly in 3-inch pots, leaving room for top-dressing when required by about half filling the pots, plunging these in a bottom heat of 85° to 90° near the glass. The plants will be available for planting in houses, pits, or frames. All points considered, there is no better variety than a selected stock of Telegraph, but there are numberless varieties of great excellence, each grower having his particular favourite, and often of his own raising or selection.

Figs.—*Early Forced Trees in Pots.*—The terminal buds having started advantage should be taken of mild weather that may prevail for increasing the mean temperature of the house, as when Figs are fairly started into growth they delight in a good heat, plenty of moisture, and all the light that can possibly be given them, admitting air so as to prevent the glass being constantly covered with moisture; but seek increase of temperature from fire heat combined with sun heat in preference to maintaining a temperature in dull weather, and especially at night, that will cause any great advance in growth at those times. Maintain a night temperature of 55° to 60°, ventilate a little at 70°, losing no opportunity of admitting a little air when the morning promises an increase from gleams of sun, and close sufficiently early

for the temperature to run up to 80°. Syringe the trees and damp the walls twice on fine days, morning and early afternoon; but when the weather is dull and wet omit the latter and damp the floors in the evening instead, as the trees are weakened and the foliage made soft by keeping them wet during the night, therefore always allow the trees to become fairly dry before nightfall. Be careful not to permit the heat about the pots to exceed 70° to 75°, and if the materials are heating too violently turn them as a means of reducing the bottom heat, but it ought to be kept steady.

Early House of Planted-out Trees.—This is an excellent means of securing the finest Figs early in June, the trees being confined to narrow borders about one-third the width of the house, and the soil a calcareous loam on a stratum of limestone or sandstone, so as to insure perfect drainage with superfluous water carried off by a drain. Maintain a night temperature of 50°, 55° by day, and 60° to 65° from sun heat. If conveniently arranged for the introduction of a good body of fermenting materials, as leaves and one-third of stable litter, the atmosphere will be kept uniformly moist and genial, lessening the need of fire heat. Trees that have been started about the same time for a number of years push growths with little excitement; but young trees that have not been forced start tardily, and are often given more heat in the early stages than is good for the crop. This should be avoided by bringing on the trees slowly, seeking advancement from sun heat more than artificial in dull weather. Apply water to the border not less warm than the mean of the house, bringing the soil into a thoroughly moist condition. Syringe twice a day with tepid water a little warmer than the house; but in dull weather damp available surfaces only, syringing always sufficiently early to allow the trees to become dry, or nearly so, before nightfall.

Succession Houses.—Proceed with pruning as convenient, thinning the wood where crowded, cutting back that which has reached the extremity of the trellis to growths well disposed for supplanting the branches cut away in bearing. Thoroughly cleanse the house, limewash the walls, wash the trees with carbolic or petroleum soapy water, using a brush, and the trees having been infested with scale or red spider, employ the soapy solution at a strength of 4 ozs. to a gallon of water. It is necessary to dislodge the scale, effecting that by using a half-worn brush thoroughly cleansed from paint. Remove the loose surface soil or mulching, and supply fresh lumpy loam with sprinkling of approved fertiliser. Keep the house as cool and dry as possible, merely excluding frost, or not allowing the temperature to fall many degrees below freezing point.

Young Trees in Pots.—If these are wanted for early work another season the plants should be placed in gentle heat during this month in order that they may make and properly ripen their growth by September. They must be potted without delay, using good turfy loam rather strong, with a fourth of old mortar rubbish and a fifth of thoroughly decayed cow manure, draining efficiently, and potting firmly. Train the plants with a single stem, and allow the radiating branches to form the foundation of a good bush or pyramid. Insert cuttings or eyes of any varieties it is desired to increase, and in order to make a good growth they should be encouraged with bottom heat, and started not later than the beginning of February.

PLANT HOUSES.

Loam.—If a large stock has not been wheeled under cover, no time should be lost in doing so, to have it in good condition for use when required. As opportunity offers it should be pulled to pieces and the worms removed. As this work proceeds it is a wise plan to select the most fibrous portions, and store for choice plants that need a compost of this nature. This is readily accomplished by the aid of an inch sieve. That which passes through should be again placed in a finer sieve, and the particles that pass through reserved for seeds, seedlings, cuttings, and small plants where a rough compost would prove unsuitable and out of place. It is surprising when a large amount of loam is prepared for use in this manner how quickly the work of potting, filling pans and boxes for seeds and cuttings can be carried on. It is a mistake to leave work of this nature until the busy season of the year.

Leaf Mould.—The amount required for use during the spring months should also be under cover, ready for preparation during unfavourable weather. This undergoes a similar process to the loam, differing only in being passed through a sieve with a half-inch mesh. A heap of rough material may also be prepared by breaking it up with a fork, removing the finest particles by the aid of a sieve, sticks also being carefully picked out. This rough heap, when cleaned, will be found useful for placing over the drainage of many plants, and incorporating with composts that are required as rough as possible. Our leaf mould is never stacked or used for potting purposes when too much decomposed. We prefer it when the fibre of the leaves is still perfectly fresh, which will be the case if the leaves have not laid more than 1 foot in depth, and are fully exposed.

Peat.—Sort this into three classes, that with the most fibre being reserved for Orchids, the hardest for Azaleas, Heaths, and other hard-wooded plants, while the lightest will do for Ferns. For the two latter it should simply be broken up with the hand, and Fern roots, pieces of wood, and strong roots of Heaths removed; while that required for Orchids should have all the particles of soil shaken out of it, which will be useful for many small Ferns, Mosses, and other plants.

Manure.—When much potting has to be done at various times of the year it is necessary to wheel into a shed good heaps of manure in

autumn and at the present time. The autumn supply consisted of cow manure, from which the straw was shaken out, and horse droppings. The former, if moderately dry when stored, will rub easily through a half-inch sieve. It is useless to sift it if not dry enough, for if laid thickly together the labour of sifting would be wasted. If not sufficiently dry place it in boxes or flat hampers for a few days in the boiler house or other position to dry. Be careful that it is not baked, for this evil is as bad as sifting it when too wet. The horse droppings should be in good condition for passing through a sieve. The preparation of manure for potting is important; it cannot well be too finely divided for incorporating with other adhesive ingredients. If it is wet and adhesive it renders a compost with which it may be mixed unsuitable for use. Cow manure may be stored twelve months previous to being used when perfectly fresh. Our plan is to place it in an old shed and surround it with dry loam to soak up all the liquid that runs from it. This loam is equal to manure for many plants afterwards. As it is removed from the manure heap it is mixed with equal quantities of dry loam and a fresh supply placed round the heap of manure. No waste takes place by this method, and the loam that has been soaked with manure will be found invaluable for *Richardias*, *Chrysanthemums*, and plants of a similar nature.

Artificial Manures.—The stock required for the year's supply should be ordered, so that it will be ready for use when required. Amongst these may be included half and quarter-inch bones with the fine left in, as well as a supply of meal. A box or barrel of soot should also be placed handy for use, and a few barrowfuls of wood ashes. Very few plants dislike the two latter, and either may be beneficially used in the majority of composts where loam, leaf mould, and manure are mainly employed.

Sand.—If the supply of the former is not equal to what will be required no time should be lost in getting in the necessary quantity. For mixing with composts it is much better dry than wet, especially early in the season when other ingredients have a tendency to be moist.

Pots and Crocks.—The former should all be washed ready for use where they are not cleaned as they are emptied and stored away in their sizes. The crocks must be thoroughly washed; this is as important as using clean pots. The drainage of many plants is rendered untimely defective by the use of dirty crocks. When washed and dry sort and break them into various sizes ready for use, and place them separately. This is quickly done by the aid of sieves, except the largest or two largest sizes, and this can be selected during the process of breaking, and should be placed on one side first.

Labels and Stakes.—The first we have long since discontinued making, for they can now be purchased so cheaply. The necessary quantity should be ordered ready for use, and relabelling can be done as far as possible. It is a mistake to leave it until the different plants require potting, as is too frequently the case. Repoint stakes and tie them in sizes, it can then be seen what sizes and the quantity that will be needed. These, if bought, should be placed in early so that they can be pointed. Small stakes for a variety of purposes are generally in demand, and for this purpose large Bamboos are bought, cut into lengths, and split; the sharp edges are merely taken off with a knife, and the stakes pointed at one end.

Boxes.—Some will decay, and to keep a good stock in condition for use a few should be made annually. We use common floor boards 6 inches wide. The ends and sides only want sawing into lengths. The bottoms are soon nailed on if the width is such that two or three boards without sawing will cover it. For three boards placed lengthways the boxes should be 19 inches wide, which will allow two half-inch spaces for drainage. If shallow boxes only are needed the boards may be sawed straight down the centre. Boxes last half as long again when thoroughly painted inside and out before they are used.

SPINACH.—An interesting bulletin prepared by Mr. L. F. Kinney of the Rhode Island Experiment Station, treats of Spinach with a description of the most approved methods of culture at the present day, the protection of plants against mildews and leaf-miners and various other interesting points. In the matter of classification, four types of true Spinach which have originated from the natural species, *Spinacea oleracea*, are considered. The first of these is the Norfolk or Bloomsdale variety, which makes a vase-formed, thick-leaved plant, with leaves supported by stalks instead of resting on the ground. This type is not popular among the large growers because it goes to seed early, and yet it is unsurpassed in quality when harvested at the right time. The Round-leaved Spinach is the second type, and it makes a compact round plant with dark green, slow growing leaves formed close to the ground. The third type is the Thick-leaved Spinach, which has the ends of the leaves pointed. It grows to a large size very rapidly. The Prickly-seed Spinach has leaves with long, slender stalks and narrow blades, and is not planted in the north as much as it deserves. The so-called New Zealand Spinach is botanically *Tetragonia expansa*, which, when properly cooked, makes a good substitute for Spinach, and can be grown during the hot summer months, when it is impracticable to grow the true Spinach. The Mountain Spinach, or Garden Orache, is botanically *Atriplex hortensis*, and none of its forms has much to recommend it. Spinach has been cultivated for a thousand years, but it was not grown in European gardens until the fifteenth or sixteenth century, and the greatest progress in its cultivation has been made within the last fifty years.—("Garden and Forest.")

THE BEE-KEEPER.

HIVES WITH TEN STANDARD FRAMES.

I HAIL with pleasure the remarks of George Howdenshire (page 618) on this subject. He says, "Is a hive with ten standard frames large enough?" and have no hesitation in saying it is not.

At this season, when all is quiet in the apiary, a discussion between practical bee-keepers will be beneficial to all who are anxious to improve, as far as is possible, on the various methods of bee management. I take it for granted that the chief aim of bee-keepers is to obtain a rich harvest of honey; the fertilisation of their own and neighbours' fruit trees when in bloom being only a secondary consideration.

How is this to be done? Will bees store more honey in a hive holding ten standard frames, which in due course at the proper season has another hive of the same dimensions placed on the top and holding the same number of frames, or a hive holding twenty frames of the same size? I have experimented, not once but dozens of times, with hives of the above dimensions, and whether it has been for weight or quality of honey, or ease in manipulation, I must own to having a strong liking for the former. Your correspondent has not carefully read my previous notes on this subject, or he would not have propounded the above query.

I prefer a hive with sufficient space for ten standard frames, because a strong colony of bees will store sufficient (whether it be honey or sugar) for their requirements until a limited quantity is obtained from the early spring flowers. I fail to see the advantage derived from allowing 100 lbs. of honey to remain in the body of the hive, and twelve frames, at least, of sealed-up stores would not be beneficial to the bees. Again, if looked at from the profitable side of bee-keeping, my wholesale price of honey obtained during the past season was 7d. per lb.; granulated sugar for autumn feeding cost less than 2d. per lb.

If no other reason were forthcoming, this is sufficient, when profit and loss is taken into account, to prove that it is not wise to allow a large surplus of honey to remain in the hives during the winter. If a rapid feeder is used, and the bees are fed early in the autumn, a strong colony will carry down sufficient syrup in forty-eight hours to provide for all their wants until the following spring. I never under any pretence extract honey from the body of the hive; and if a large hive is used, brood will be found in nearly all the frames by the time the white Clover is in bloom. This may be prevented, if run honey is required, by placing a sheet of queen excluder zinc between the frames. If comb honey is required this is not necessary, as a strong colony will readily work in sections.

Bees will always store honey more freely in supers (whether they are frames or sections) when placed directly over the brood nest than if placed on the same level in the body of the hive. Run, or extracted honey, is so much superior when obtained from supers free from brood and pollen, and in no other form have I been able to procure so good a sample as from

THE DOUBLING SYSTEM.

In advocating a ten-frame hive I will state how I obtain as much bee room as those who favour much larger hives. If bees are confined to only ten frames the space is too limited to obtain a surplus, and instead of gathering honey they will in all probability have the swarming mania, and by the time they have settled down to work the honey flow will be over.

The secret of the successful management of bees is in doing the necessary work at the right time, not leaving until to-morrow, or it may be next week, what ought to be done to-day. If the hives are numbered (as they always should be), and a note made of the age of the queens, select those stocks having a young fertile queen hatched the previous season. It will take about six weeks to build up a colony of sufficient strength to take full advantage of the honey flow. Our chief aim is to obtain as much honey as possible from the white Clover, which is usually in bloom in this locality (South Yorkshire) from the middle of June to the middle of July, lasting a little over three weeks.

If we could command bright days and warm nights the whole of that time a strong colony in a good Clover district would, I have no doubt, store the 250 lbs. that "G. H." wants but probably does not often get. By the first week in June, if the selected stocks have done well, each will be overflowing with bees. The first hive to be operated on should then be examined, a fine day being chosen when the bees are busy working. Lift out the frame; until the queen is found, and place the frame containing the queen on one side. Remove four or five of the frames from the centre of the brood nest, and replace with fully drawn out combs or full

sheets of foundation, the comb containing the queen and adhering bees being replaced in the hive. A sheet of queen excluder zinc should then be placed over the top of the frames; this will keep the queen and drones in the bottom hive.

Another hive the same size is then placed on the top and filled with empty comb, and the frames with adhering bees previously removed from the brood nest. If not of sufficient strength some frames of brood and the adhering bees may be taken from other stocks which are headed by old queens, care being taken that the queen is not removed.

The bees on these combs, if placed alternately with the others, will settle down as one happy family. Nine frames will be sufficient in the top storey, as this will allow the cells to be drawn out longer than they otherwise would, and more honey will be stored. All intended for extracting purposes may be treated in the same manner, those that are weak being made strong from the stocks having old queens, and from which young queens will be reared for another season.

It will thus be seen that colonies treated as above will be of great strength owing to the thousands of young bees that will be hatched before the honey flow comes, ready to take advantage of the first fine day that comes, thus showing that the maxim is true in bee-keeping as in many other things, "Unity is strength."—AN ENGLISH BEE-KEEPER.

AN ENGLISH BEE-KEEPER AT HOME.

DURING the summer of 1896 an opportunity occurred of paying a visit to "An English Bee-keeper" at home, when we were able to enter closely into his system of management. We did so, and found it excellent; we also examined the results and found them pecuniarily highly gratifying.

We do not wish to infer that his system of bee-keeping is the only one that can be profitably followed—not in the least, as we know of other experts who have achieved good results by different methods of management. We do, however, know that the lines followed by "An English Bee-keeper," and which he so lucidly explains week by week in these columns, are sound, and may safely be adopted by the beginner, and probably also by some who may have followed bee-keeping and not been successful.

It must be understood that our excellent coadjutor has reduced the practice of bee-keeping to a science. He keeps the most minute data from day to day and year to year, and his records of experiments are of the greatest interest and value. Nothing is too trivial for notice; the note-book, in which each hive has its special number, is constantly in use, with the result that the condition of every stock in the apiary can be seen at a glance. Not only can comparisons of the various stocks be made in the current season, but also for a series of years that is rapidly advancing in the second decades. Beyond these figures there are others denoting money, and showing the amounts paid and received in connection with the bees each year; and though some seasons have been comparatively bad, the records show how profitable bee-keeping has proved over the whole period, thus demonstrating the essentially practical nature of the system of management.

The whole of the work in the apiary is done by its owner, and it is equipped in the most efficient manner. Not that it is the home of things elaborate or fanciful; on the contrary, it is wholly practical, everything being found that is useful and necessary, and nothing that tends only to show and ornamentation. Good as "An English Bee-keeper" is amongst his bees, he is equally as ready with his pen, and this fluency relieves us of going into elaborate details regarding his procedure—indeed such would only be occupying valuable space unnecessarily, as all readers of the bee notes will, from his writings, be quite familiar with it. We may, however, add in conclusion to what he attributes his success, and in his own words—"I have been successful in bee-keeping because, firstly, I have worked on economical, yet complete lines; secondly, I have paid the strictest attention to apparently insignificant details; and thirdly, I have given incessant attention, doing any work immediately on finding it was necessary." To sum up, we might say that "An English Bee-keeper's" motto is "thoroughness;" and no better samples of honey than his, and few so good, have been received at this office.

* * All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

* **Cattleya Prince of Wales** (*Young Orchid Grower*).—See note and woodcut on page 11 for the information you require relative to this charming Orchid.

Water Pots (*X. Y. Z., Lincs*).—As the water pots you mention have not been advertised in our columns, we do not possess the address of the makers, or would furnish it to you with pleasure. We have heard they are good, but have not used them.

Maréchal Niel Roses (*Nemo*).—If you propose to make the Roses the principal feature of the house, you might imitate a plan which we find to be both convenient and profitable—namely, to plant them out at the front of the house, and train them up wires very similar to Peaches. You do not mention the height of the front wall, but assuming it to be from 2 to 3 feet you could get a plant budded on to a standard Briar so as to bring the growths to a level with the lowest wire. Shorten to five or six eyes, and train the resulting shoots in the form of a fan across the wires. Immediately after flowering in spring head the growths back to the point from which they started. It is impossible to say how many flowers you would eventually get from a plant, as much would depend on local circumstances and the attention given, but we are not satisfied if we do not cut from 150 to 200. You might get more than this, you might get less. While the Rose is making its growth after being headed back we contrive to get a crop of Tomatoes off the back wall, from sturdy plants prepared for putting out, with fruit clusters already showing. "Niels" grown on this system have borne splendid clusters for ten years. Success with the Maréchal out of doors in your locality is doubtful, as it may be too damp to insure thoroughly ripened wood. We should proceed by experiment.

Tomatoes in Troughs (*S. L.*).—A few words were accidentally omitted from the remarks to which you refer. The Tomatoes, which grew so well and fruited so abundantly in 8 inches of firm loam on 6 inches of chalk, were in a border about 4 feet wide. The house was new, and the first crop paid for the cost of its erection. We have also seen Tomatoes grown in troughs 9 inches wide and deep, cover the roof of a house, like Vines, and bearing scarlet clusters of Tomatoes from base to summit. Further, we have seen and measured stems of Tomatoes 17 feet long roped with fruit, the plants being grown in a trough 9 inches wide, and 15 inches deep, or just the size you mention. In neither of these troughs was chalk employed as drainage material, but in the one 15 inches deep crushed lime rubbish and dry wood ashes were mixed with the turfy loam that was made quite firm. Also in both cases top-dressings of rich loam were given from time to time, which became netted with feeding roots, and liquid support was given freely when the plants were bearing. The border referred to was surfaced with manure, and the free drainage further admitted of copious supplies of water and liquid manure being given without souring the soil. With

a dense mass of roots, and others ever forming, it is almost astonishing to see what Tomatoes can be made to do in a small bulk of soil *plus* liquid support given just when needed. The mistake that many growers make is in having borders too rich, light, and deep at the outset, thus inciting succulent growth, which is the reverse of fruitful, even if the plants do not fall a prey to their enemies. Of course, some Tomatoes grow much more strongly than others. The variety that fruited freely to a length of 17 feet was Ham Green Favourite.

The Strawberry Everlasting (*Countryman*).—This is a plant that is seldom seen, and we are not surprised at your not being familiar with it. The botanical name is *Astelma eximium*. The bracts are of a rich rosy tint, and incurved so as to form close heads, bearing some resemblance to Strawberries. The plant is a native of the Cape, and has long been known in this country, but is not often seen. The woodcut (fig. 7) represents the flower head and bracts of the full size, one of the lower heads being shown in a young state before the central flowers have faded. The leaves and stem are whitish green in colour, and thickly clothed with a woolly pubescence. The dried flower heads are employed for the same purpose as other Everlastings. The plant is not

FIG. 7.—THE STRAWBERRY EVERLASTING.

generally cultivated in this country, the market supply being obtained we believe, from the Cape of Good Hope. Seed might possibly be obtained from dealers in this country, but we have not observed it offered.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (S. P.).—1, Dutch Mignonne; 2, Court Pendu Plat; 3, probably a local seedling, worthless; 4, Catillac; 5, Uvedale's St. Germain; 6, unknown. (G. C. N.).—1, Worcester Pomeroy; 2, D'Arcy Spice; 3, Wellington. (K. A. A.).—Pears: 1, Beurré Superfin; 2, Winter Nelis. Apples: 1, A variety of Blenheim Pippin; 2, Ribston Pippin; 3, Cat's Head; 4, Lemon Pippin. (L. W. C.).—1, Seedling from Blenheim Orange; 2, An unknown seedling, worthless; 3, Wyken Pippin. (G. K.).—1, Doyenné Goubault; 2, Bergamotte Rouge; 3, Duc d'Aumale; 4, Beurré Capiaumont; 5, Spanish Warden; 6, Doyenné Defays.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. L.).—Owing to having been in the post over Sunday, in addition to bad packing, your scraps were quite dead. Had they reached us in a fresh state they would have been insufficient for positive identification. (F. O. O.).—*Luculia gratissima*. (B. G. D.).—1, *Justicia carnea*; 2, Paper White Narcissus; 3, a variety of double white Primula; 4, dead; 5, *Adiantum farleyense*; 6, *Asplenium bulbiferum*.

GATES.

OLD age and failing memory go together, but I almost think one of the distinguishing marks of the sluggard was his gate which hung on one hinge—inconvenient, if nothing else. You can almost tell at a glance whether any particular farmer walks round his fields or rides. Walking you can raise a gate that opens hardly, for riding you must have them hung with such nicety that they

can easily be opened with a hunting crop or the hooked end of an Ash plant, and so necessitate no dismounting.

Of course, if a man is very tidy, even though he be a walker, he looks well to his gates, knowing them to be, as it were, an index to his whole system of management. Gates are not costly, and well hung and well gas tarred or painted should have a fairly long life. Of course much depends upon the class of stock grazed in the field. Young horses are perhaps the most destructive, but a small round rod of iron on the top bar of the gate, raised about half an inch, and a little barbed wire, will prove a salutary check, and will do them no harm.

A gate must combine lightness and strength (quite a possible combination with good material and good design), and pains must be taken to see that the posts are long enough, strong enough, and firm enough. The question as to style must be left to individual taste, as almost each county has its own particular pattern. Remember, a gate too heavy knocks itself to pieces without any extraneous aid. Get the best wood your means will allow. Oak comes first, and where oak is plentiful use it without grudging. Ash, once cheap, is now too dear as a rule for ordinary farm gates. Well-grown larch from strong land has great tenacity of fibre and wears well. There is much wood that is absolutely useless, and yet is made up "because it is so cheap." Yes, certainly cheap when it snaps and breaks in every direction. Pitch pine is one of the chief defaulters. If you do use foreign wood let it be the best that can be bought. Baltic red deal well creosoted will be of long duration.

There is a difference of opinion as to the merits of rivets *v.* nails. Rivets are bad to manage, though neat in appearance. Good steel nails are perhaps the best for the average workman's use, for they are very pliable, and can be riveted to perfection.

For posts again oak comes first and foremost (not green by any means), with at least four years' seasoning. Creosoted Norway spars make capital gate posts, and may be preserved almost everlastingly by fresh coats of tar or creosote. Where stone or slate can be got (say Derbyshire or Wales) by all means use it. Stone or slate must be set in cement. The jaw bones of the whale^e used in old days to be seen (relics from the Greenland fisheries) I do not know of more than one pair left now. Have you seen the tops of old posts covered with lead? I have, but not lately; I suppose they were too attractive to the bullet-making boy.

Give the top of the post slope enough, and plenty of paint so that there can be no lodgment of rain water to work decay. It is no use to think the gate post can be set anyhow; the life of the gate depends on the stability of its support. Make the hole deep enough and wide enough; remember there must be as much post out of sight as in sight. Have you ever thought how far and how deep the roots of trees extend? Shall you be surprised to learn that roots and branches pretty well balance one another? Nature is a good guide. In counties where flat stones are procurable they are used as wedges. Carefully dibble the soil in a bit at a time, ram it well home (idle men need not apply for this job), do not be in a hurry, and do not spare labour. Where expense is no great consideration a trench cut deeply from post to post to receive a beam, which acts as a wedge, is a fine idea. Cover the beam with soil, and just below the level of the gateway put in another beam. Some posts, again, are set in concrete; this allows of economy in wood, as the post need not be so long.

Too much stress cannot be laid on the hanging of the gate, and not one man in a hundred knows how to do it properly. In the ordinary way I will be bound to say the nose drags on the ground in less than a fortnight, and nothing can be more conducive to the destruction of the gate and to the destruction of the tempers of those who use it. The tendency of the gate is always to fall from the heel post. Short hook at the top, longer at the bottom, and both set well clear of the ground, will be found a preventive. The difference in length of hook must be at least 2½ inches.

The top hook should go through the post, and be secured with

a nut. This allows of a little adjustment as time passes. If the gate is meant to be self-closing greater length of hook must be given at the bottom. It is well to make gates at least partly self-closing. There is such a natural disinclination in the human breast to shut gates, that it is well to make the process as easy as possible. A gate that works stiffly is invariably left open, except by the most conscientious. The simpler the fastening the better, bearing in mind there are always shifty old cows and cunning old horses that can open any gate in creation. A gate that opens outwards on to a road is most unsightly, and also may become a source of great danger.

In painting again individual taste must have play. There is one rule that admits of no exception—*i.e.*, whatever be the colour see to the quality; let it be the best that money can buy. Coal tar looks well and lasts well, but is possibly a little funereal. One old friend always chose a deep good red; he said it gave a warm tone to the landscape, and it certainly wore well. Beside the consideration of smartness, it should be borne in mind that in this damp humid climate all outside woodwork must be well protected by paint if it is to last out half its life, and nowadays we require full value for every halfpenny expended on the farm or its belongings.

WORK ON THE HOME FARM.

The weather has again become very mild, and the rainfall has been considerable. The later sown Wheat is getting well out of the ground, and freedom from frost for another fortnight would see it well established, and safe at any rate from the ravages of the birds.

We have about finished manuring Clover stubble for a crop of Potatoes, and are commencing to plough it in 10 inches deep with chilled ploughs. Three horses in a plough will do an acre a day comfortably. We are also ploughing lea for Oats with the same ploughs, but not so deep; only about 7 inches in this case. We are doing this ploughing none too soon, for the sod must be fairly decomposed and the land solid before the seed is drilled, and we hope to have it in about the 1st of March.

The spare hands are busy with hedging, which has got considerably in arrear. The district councils are requiring the fences adjoining roads to be kept low, which is causing friction with occupiers, who do not like parting with shelter for their stock. Some fences have been allowed to become much too high, and as it is not always the highest fence that provides the best shelter the owners may be benefited against their will.

Sheep on Turnips on heavy land have been through a trying time lately. The folds after the thaw were in a dreadful state—a puddled mass—and many flocks have been removed to grass altogether for a time. We heard of large numbers having to be carted out of the field; they could not stand, much less walk. Fine weather is wanted very urgently to put things right; in fact, it is wanted by farmers now for every reason. Fallows are exceedingly wet, and will require a good spell of drying winds before they can be workable.

Potatoes move off very slowly; a sudden spurt one week is followed by a dead stop the week after. We are making them a very good sample, and keeping a considerable quantity for the cattle. These latter will consume as many as we can spare for them, for Turnips become relatively scarcer as time passes, and there is certain to be a scarcity before spring.

REMARKS.

27th.—Bright sun all day; fine night
28th.—Squally and rainy till 10 A.M., dull and showery after.
29th.—A brilliant day, marred almost throughout by more or less London smoke.
30th.—Mild and dull.
31st.—Rain in small hours; bright sun from sunrise to noon; dull and drizzly from 2 P.M. to 5 P.M.; fair evening.
1st.—Rain at 6 A.M.; fair after, and brilliant from 10 A.M. to midnight.
2nd.—Foggy throughout.
A variable week, with temperature rather above the average.—G. J. SYMONS.

NOW READY.

BARR'S SEED GUIDE

For **1897.**

FREE TO INTENDING PURCHASERS.

VEGETABLE SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Select List of the Best Vegetables for securing a supply of Vegetable Seeds "the year round."

FLOWER SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Choice List of the best Seeds for the Flower Garden and Greenhouse.

ALL SEEDS CARRIAGE PAID ON RECEIPT OF REMITTANCE.

We guarantee all our Seeds to be of the finest selected strains, and of highest growing quality.

For 1897,

OF

Vegetable & Flower Seeds

AND

BULBS & PLANTS.

IS NOW READY.

Will be sent post free on application to their Offices at OVERVEEN, near HAARLEM, HOLLAND, or to their General Agents—

Messrs. MERTENS & CO.,

3, CROSS LANE, LONDON, E.C.

No. 864.—VOL. XXXIV., THIRD SERIES.

Barter's TESTED SEEDS.

The Best Vegetables
and Fruit for Early Use.

SOW AT ONCE

CARTERS' FORCING PEA.

A New Winter and Spring Marrow, valuable for under-glass culture. Height, one foot.

In Sealed Packets, price 2s. 6d. per Pint, post free.

CARTERS' STRINGLESS FRENCH BEAN.

An extra early dwarf green-podded variety.

Mr. O. J. TALLACK says:—"It is the quickest to come into use I have ever grown."

In Sealed Packets, price 2s. 6d. per Pint, 4s. per Quart, post free.

CARTERS' LONG FORCING CARROT.

Quite a new type, retaining its colour under forcing culture. The Garden says:—"It grows as quickly as the earliest, and is a decided acquisition."

In Sealed Packets, price 1s. 6d. each, post free.

CARTERS' EARLIEST of ALL CUCUMBER

In a careful trial for earliness, this fine variety was proved the quickest to finish its fruits by nine days.

In Sealed Packets, price 2s. 6d. each, post free.

CARTERS' HARBINGER LETTUCE.

Valuable for under-glass culture, where early salading material is required.

In Sealed Packets, price 1s. 6d. each, post free.

CARTERS' BLENHEIM ORANGE MELON.

This grand scarlet-fleshed Melon is one of the quickest to ripen its fruit, and is very largely grown for early summer use.

In Sealed Packets, price 2s. 6d. each, post free.

CARTERS' DELICATESSE RADISH.

A greatly improved type of the French Breakfast Radish, introduced by us many years ago. Very suitable for forcing.

In Sealed Packets, price 8d. per Ounce, 3s. 6d. per Pint, post free.

CARTERS' DUKE OF YORK TOMATO.

This grand variety is now grown in the best establishments in preference to all others. Its record upon the exhibition table is also unapproached by any other Tomato.

In Sealed Packets, price 2s. 6d. and 3s. 6d. per Packet, post free.

Illustrated CATALOGUE, Gratis and Post Free.

Journal of Horticulture.

THURSDAY, JANUARY 14, 1897.

LOOKING FORWARD.

TIME flies! Another year has passed away with its pleasures and disappointments, leaving behind, let us hope, many pleasing recollections of good work honestly performed. Whatever the past may have been it is now beyond recall, and we have entered upon another stage in life's journey, a stage that perhaps will give us many opportunities of profiting by past experience, and thus avoiding errors in the future. It is, doubtless, sometimes good to take a retrospective glance, but I think unwise to allow our thoughts to dwell long upon events that "live only in the memory," for we live in times when there is no room for dreamers, but which offer splendid opportunities for "men of action." "Go forward" is the motto, which it seems more than ever necessary to adopt during these closing years of the nineteenth century.

There is every reason to believe that the present year will be a memorable one in the annals of horticulture. Already we have had placed before us in the pages of "Our Journal" several well thought out schemes by which horticulturists may commemorate the "Queen's long reign." Whichever of those schemes is eventually adopted I doubt not that willing and able men will be found to carry them out in a way worthy of so great an occasion. It is a matter of thankfulness for all, and I believe that every gardener in Britain would be ready to contribute a mite towards the necessary funds. Without appealing to high-flown sentiment it should not be difficult for us to see how largely all have benefited by the priceless blessings of liberty and comparative peace which the nation has enjoyed during the progress of the Victorian era. With the strong arm of the mother country to protect them these little islands have sent forth sons and daughters to form thriving colonies in distant lands, colonies which have extended and held out a hand to each other until at length they have formed a belt around the globe, carrying with them the just laws and sturdy vigour of a great race.

Can we imagine what Britain would have been to-day without this marvellous expansion, or measure the good it has done toward the progress of the world? All nations have

benefited by the colonial enterprise of Britain, for has it not provided a market for their goods and a home for those who seek their fortunes in distant lands, where the security of a protecting arm gives the necessary incentive to exertion? Gardeners, among other classes, have largely benefited by these advantages, for when the outlook at home has not been encouraging they have sought, and not in vain, their fortunes in other climes. Their cultural knowledge and grasp of detail has often in such instances speedily secured for them important posts. Others, whose inclination ran in the direction of owning a "bit of land" of their own, have succeeded by unflinching perseverance in establishing themselves upon their own farm or fruit garden, there to gather the fruits of their early labours till the end of their days. The stream of emigration continues to flow, and although at times we hear tales of woeful failure, I think if we could trace such failures to their true cause we should find but little reason for surprise. Failures we see at home in plenty, but the man with "grit," health, and a clear head usually manages to keep his head above water.

I claim in my humble way to be a student of human nature. It has always been my hobby to mark well the men I come in contact with. Should one of those individuals whom some call "lucky" cross my path, I find a good opportunity for mental notetaking, and during the process I invariably notice that the so-called lucky one has that undefinable "something" about him that must lead to distinction in one direction or another. These lucky ones could, I think, often tell us of struggles and exertions that do not appear upon the surface, neither are they recorded by word or pen. We are all perhaps too much inclined to think the dark days of adversity will last for ever. The failing of the age seems to be the want of a strong spirit of hope, and in my own mind I doubt not that this deficiency is the cause of failure with not a few; certain it is that given two men with equal advantages, ability, and tenacity of purpose, the one with the greater amount of hopefulness will, in the battle of life, leave the other far behind. How necessary, then, it is for us all to cultivate the habit of looking on the brighter side of life. No matter how dark our prospects may be, there is always a brighter side; and the blackest clouds have a habit of passing quickly away, to be followed by the full tide of bright prosperity.

At the beginning of each year it is especially desirable for all to look forward in anticipation of a prosperous time. Horticulture, like agriculture, has been passing through a long period of depression; happily, however, signs are not wanting that the clouds are breaking. The value of land is steadily increasing, and many uncultivated farms are being taken in hand again. We also hear from various sources that the nursery trade is in a fairly prosperous condition. These things are as little gleams of light to horticulturists who have long been watching for such welcome signs. These signs will also be especially welcome to those gardeners who are still "looking for an engagement," many of whom are perhaps well nigh weary of the waiting. 'Tis a sickening task, still the turn of the tide must come, and he who sticks close to duty will assuredly reap in some way his reward.—ONWARD.

PRECEPT AND PRACTICE.

In the "Canterbury Tales" Chaucer describes a certain dame as one "who often took leave, yet was loth to depart." This aptly expresses my feelings on being called back to a congenial theme by the hint courteously conveyed at the end of "The Gardener's Path" (page 554, December 10th, 1896). It would ill become me not to respond, and at least try to furbish up some little things from memory's storehouse as helps to our young men who are training and being trained in the glorious vocation of a gardener.

I must confess to having been a little mystified when considering

the lines upon which to proceed, and as it would not do to set out in a mist I begged of an older boy to throw a light upon the subject from his lamp of experience—to define the boundaries of our peregrinations in the pursuit and acquirement of knowledge, and we must thank him for his illumination, which again sets us going without any danger, I think, of getting lost in the fog.

Probably we shall not follow the subject upon strictly orthodox lines, nor upon those more sharply defined, over which you are being ably conducted by the most experienced guides, such as those who point the way in "Hardy Flower Notes," Orchids, Roses, Chrysanthemums, fruit culture, and the principal features of elementary or up-to-date gardening; but, as an old hand described his method of planting as "zigzagging," we will "zigzag," and, I trust, set down many little things which may be both useful and ornamental in our vast field; so vast, indeed, that diffidence shall not prevent me in again tuning my pipes for that long dance I fain would lead you.

Having caught the flashes from my esteemed illuminator's lamp, they may be turned on here to show the way better than any further preamble of mine would do. I—an Old Boy—asked Mr. Older Boy, as before mentioned, to define the boundaries of this fresh survey; what he sees, what he does not see, and what he says are as equally worthy of your attention as they have been of mine; therefore mark, learn, and inwardly digest the following, I beseech you.

"I should not like to try and limit the boundaries of the illimitable—education. I can see no boundary but the grave, if that. The gardeners of the future must be accomplished; must be educated in head, hand, and heart; as proficient as they can make themselves in the arts and sciences bearing on their vocation. They must be educated in discretion, learn to know themselves and others whom they serve or with whom they associate. Educate themselves in the amenities of life—in demeanour, conversation, and correspondence; also in botany, etymology, vegetable physiology, geology—at least in part; in the laws of nomenclature, and, in fact, in everything bearing upon their duties, and in the building up of themselves as men; in arithmetic, for accounts; mensuration, and estimates in planning, drawing, and execution; in the use of all kinds of instruments pertaining to the art, from the spade and the hoe to the compasses and pen. They must be skilled artificers in everything within the scope of their duty, regarding all work, light or heavy, at the desk or on the land, as intellectual work, and glory in it. It is only then that it will be pleasurable, and only when it is so can the highest excellence be attained. For this all may and should strive, and those who approach the nearest to an ideal of scientific and practical competency are the best, the most esteemed men, and the best of either men or material always did and always will find the way to the front."

"There is a loud, wild cry of 'too many gardeners.' It is a hollow sound—a fallacy. There are too many calling themselves gardeners, which is quite another thing. But how is all this multifarious knowledge for the making of real gardeners to be obtained? There must be, first, desire—strong yearning, fed by ambition; secondly, keen cultivated powers of observation. Then acquired quickness of perception and retention of impressions. Diligence, not of the common fitful order, but the much rarer constant kind, which difficulties strengthen. In the pursuit of these attributes health must be maintained as far as possible by prudent habits of life. Among the real obstacles of life one of the greatest is self-sufficiency in knowledge, which means ignorance; another is over-indulgence in pleasures of a sporting nature. If bad habits cannot be prevented or overcome their victims must be swamped in the great deep sea of lost opportunities."

I must claim the indulgence of Mr. Older Boy for having turned this powerful light upon our course to its full extent—that is, so far as the rays were revealed to me. How much candle power there might be in reserve I will not contemplate, but to our readers no apology need be tendered, for I would not have deprived them of one ray—one light or shadow—he has thrown upon the subject. And now young travellers I move that we adjourn ere I trim my flickering taper by which precept and practice may be zigzagged through the daily planting of a young gardener's life. In doing so I have heard more than one of you propose a hearty vote of thanks to our experienced illuminator, which is gratefully seconded by—AN OLD BOY.

(To be continued.)

A DREAM OF FAIR GARDENS.

ONLY a dream, courteous reader, a reminiscence. This is no day for gardening; the wind is in the south-east, and half a gale is blowing. It is nearly a mile, as the crow flies, to the sea, and yet one may hear the turmoil—the wild music of the storm. One may only hear that trio by the sea—the deep thunder of the waves as they break into clouds of white foam, the sonorous tenor of the wind as it rushes through the bare branches of the Elms, and now and again the shrill piccolo of the Bay tree leaves by my window as it chafes on the pane. "It is an ill wind," as the old saying is, "that blows no one any good," and therefore one must not complain. The last gale scattered along the shore here at least 200 tons of seaweed—one of the richest of natural manures, and it was eagerly gathered by farmers and market gardeners. And so, safely sheltered from the driving storms without, I wheel round my armchair, toss on the dog irons another billet of beech or fragrant pinewood, and conjure up some visions of the many gardens which, by the courtesy of their owners, I have seen in the time of Roses, blossoming Beanfields, and new hay.

To many of us there are few, if any, pictures more delightful than those of a garden, and, singularly enough, so few artists attempt to paint such. Perhaps not one in a hundred of the pictures hung in the Royal Academy treat of the garden, and the few there are exhibited are not the work of *men*. But the pictures I think of are not of canvas, colour, and brush; they are fair Flora's own. To those who look in earnest it is only to close the camera of memory for a brief spell and the scene reappears, the narrow environment of the dwelling melts away, and summer again steps the garden in golden sunshine and the broad landscape in a shimmering mirage.

The first garden of my dreamland is part of a large estate lying within a score miles of Charing Cross. The monogram of the noble owner is SX. We enter the kitchen garden from the high road, and pass beneath a leaf-fringed archway in a high, lichen-stained wall. On the right of the broad, smooth path is an oblong bed, perhaps 100 yards long by 6 yards wide. A neat Box edging surrounds it, and next to this is a yard-wide belt of white Pinks. Down the centre, at intervals wide apart, stand old dome-shaped Filberts, and beneath and as far as the belt of Pinks there is nothing but Lily of the Valley, Pinks and Lilies—that's all, besides the drooping Filberts. The reader may imagine the quiet elegance of such a bed, and its fragrance as early summer showers patter and sparkle among the Lilies.

A score yards distant is another broad, smooth path o'erarched by blossoming fruit trees. Less than a month before when I saw them they were in the pride of their springtide beauty. There had been a shower, and as the petals, pink and silver, fluttered down the sunshine smote them. Beneath, on each side, was a border of old English flowers—York and Lancaster Roses, great crimson Pæonies, and Solomon's Seal. A garden seat beneath was a favourite resting place of the venerable Earl. Here he would sit, with nothing to disturb his reveries but the silvery ring of the busy wing, the songs of the merle and mavis and charming linnet; while all day long and night could be heard the "amorous descants" of the nightingale.

Opening an opposite door one emerges suddenly upon the pleasure grounds in front of the Hall. Wide, smooth lawns of a texture velvety and delightful stretch away on one side towards a fine old castellated residence. Magnificent Cedars two centuries old spread great, dark flakes of foliage, inviting the visitor to a seat in the grateful shade beneath. On all sides are rare Coniferous and other trees. Over the Lilled pool there droops a Willow from sad St. Helena, there a Bay Tree from Virgil's tomb, and there is the olivary in which my lady culled her simples; there a quaint little garden of sweets, over whose protecting fences ramble Jasmine, Roses, and Honeysuckle. In the back of the fence are three circular apertures a yard in diameter, each affording a delightful picture of the woodland drives beyond.

This old garden was a favourite resort of John Evelyn; and that old and learned Stephen Switzer used to say of it, that "at Cashibury the polite spirit of gardening shone brightest," and that he "never saw that truly delightful place without being more than ever ravished by its natural beauties." By the way, our magnificent garden at Kew owes not a few of its fine specimens to the tree-monger, erst of Cashibury.

The next garden of my dreamland lies, perhaps, six miles distant by the main road, and not far from a breezy, picturesque common. It is entirely hidden from view by belts of woodland—a delightfully secluded spot away from the beaten track, and so screened by trees that not a particle of highway dust, nor a whisper of the turmoil of great London can be heard. Green meadows slope to a lake, in which flocks of wild fowl disport, while beyond rise the grey towers of old St. Alban's Abbey. We entered by the

lodge through a charming old garden, with beds of curious and beautiful herbaceous plants on each side. This mingling of flowers, fruit, and vegetables, though not fashionable, makes the so-called kitchen garden more interesting and attractive.

The chief feature of interest, however, is the delightful garden on the south. All the year round there is something to admire here, but more especially in spring and autumn. In the latter season, however, there are magnificent masses of foliage of the richest hues—Scarlet Oak, Liquidamber, Copper Beech, and varieties of the sportive Acer family. Near the centre of the lawn stands one of the finest Tulip Trees in the country. There is little trace of winter in such a garden, with its abundance of evergreen shrubs, Laurel, Bay, and Holly, and a magnificent grove of Scotch Fir—perhaps the most picturesque of British trees. Then in spring there is the wealth of lighter colours peculiar to the season: the Thorns—crimson, pink, and white; the great milk-white bosses of the Guelder Rose, the golden rain of the Laburnum, the orange scarlet of the Kalmias, the snow white clusters of Clematis montana, the elegant blue racemes of Wistaria.

But away to the far west. One might linger for hours in Mr. Bolitho's beautiful garden at Trewidden, and make fresh discoveries at almost every step, a garden fanned by moist Atlantic breezes, and nourished by a purer light; might see how the hand of the landscape gardener—probably the proprietor himself—had transformed the quarry into fairy glens in which the Tree Fern and Palms luxuriate, and things of humbler growth rejoice in the soft moist air and chastened light. But no! there is another more famous garden that I fain would see again. So taking again the wings of dreamland we flit thirty miles due west to that paradise of flowers—Tresco, in the Scilly Isles—the land of Lyonesse.

Standing on the Old Quay of St. Mary's, we see across the narrow channel a wooded islet, from the summit of which a stately house looks down. The climate of the Scillies is delicious, and as one might expect, where skill too is requisitioned, there is a wealth of foliage and flowers. In some of the cottage gardens, and by the wayside tall stems of the stately Aloes rise like huge candelabra. And then as one winds one's way through the road to the Abbey, Palm-like Dracænas and New Zealand Phlox, together with huge Hydrangeas, and Fuchsias a dozen feet high stand on each side of the drive; while the walls of Cupressus give place to bays in which flourish the rarer Rhododendrons and Tree Ferns.

As we enter the gardens by a cool, shady, Fern-draped walk we are invited by a courteous inscription to enter the enchanted grounds, so please you, and welcome. Immediately in front of us is the rock garden, in which the hollows and interstices in the granite pile are filled with flowers. That blaze of rainbow hues that flashes on the astonished visitor is not soon forgotten. For the most part it consists of Mesembryanthemums, from pure white, primrose, and orange through the gamut of rosy tones to crimson and deep purple. Myriads of blooms crowd together, eager to be kissed by the golden sunlight. It were worth while almost to watch for a passing cloud to see the rayed blossoms close and open again—but one may watch long for a summer cloud here. Tresco is the home of the Mesembryanthemum, as it is of the Daffodil. One may see patches of it growing on the wayside walls, and by the coastguardsmen's station a large succulent species clothes the banks by the beach with dense foliage and primrose-coloured flowers. In picturesque God's acre great masses of magenta blooms spread a glorious mantle over the graves of mariners saved from the sea.

The gardens at Tresco form a series of terraces on each side of a central walk, shaded by Palms, Tree Ferns, and Aloes. These plots on one side are for the most part assigned to some favourite of Flora's Court—Roses, Carnations, Lilies, Stocks, and so on. In such soil and climate herbaceous flowers run rampant, and soon revert, like the tricolor Pelargoniums, to the normal type. We pause for a moment to glance into a pretty conservatory where there is ripening, without fire heat, a fine crop of Grapes. Here grows that most elegant Glory Lily of Japan, which does not seem yet to have got into commerce. Another tree of rare elegance is the Fourcroya, a Mexican; it is from 15 to 20 feet high, with a glossy tapering stem. From the summit, dome shaped, there droop long pendulous racemes of yellow flowers, while long flag-like leaves clothe the base of the stems; but it is for the Daffodil perhaps that Tresco and St. Mary's are most noted. Wordsworth speaks of them:—

"Ten thousand saw I at a glance,
Tossing their heads in sprightly dance."

One might see there ten millions, from the Giant Emperor, Empress, Sir Watkin, and Horsefieldi, to the tiny nanus and Angel's Tears. In February and early March, when all here is sombre and frost-nipped, wide stretches of the landscape at Tresco are far more brilliant

than that Field of the Cloth of Gold of which history tells us. Beautiful, charming, delightful as these Isles of Scilly are, the landsman, not without misgiving, turns his eyes eastward, and sighs as he thinks of that thirty miles of stormy seas and the *mal de mer*.

And why, someone asks, need the Londoner *dream* of gardens? In spring and summer he has the parks, each now with its delightful parterre. Then he can ramble at will through those unique gardens of Royal Kew, enjoy the rainbow hues and sweet odours of the plant houses, sit beneath the Tree Ferns and Acacias of the temperate house, or linger among the tropical foliage in the Palm house.—T. W. H.

THOUGHTS ABOUT FRUIT GROWING.

(Concluded from page 7.)

LOOK round any of the agricultural shows held under the auspices of the Royal, or any of the county societies, you find cattle, implements, roots, and so forth, but rarely any fruit, except it be a nurseryman's honorary exhibit by way of advertisement, and yet no one will deny that fruit is in every respect a farm crop. The promoters of the shows themselves are ready to admit the importance of a better system of fruit culture, yet nothing is done at the exhibitions to encourage it. There appears to be an idea that fruit exhibiting belongs entirely to flower shows—institutions for which the average farmer shows some contempt. How few there are amongst the agricultural class consider the importance of fruit culture. In its highest sense the occupation belongs to the gardener, and with the gardener they are content to let it remain.

To deny that strides have not been taken would be absurd, and the sight of many acres of young trees taking the place of old and worn out orchards is gratifying to the enthusiast. In strictly fruit growing districts one is apt to get confounded by contrasts. In Kent, the favoured fruit growing county, this is very apparent, for here can be seen both bad, good, and indifferent. One is surprised at the condition of some of the orchards. The trees are old and cankered, and completely covered with moss and lichen growths, all so detrimental to the welfare of the trees. Insect pests abound, and no steps are taken to combat them. Can trees pay under such conditions? No, of course not; they have no chance, and the farmer sighs and complains of bad times. Here, surely, there is a want of knowledge coupled with a lack of energy, and it seems a shame to cumber the ground with such profitless trees, rendered so by long neglect and want of system.

Fortunately this cannot be termed general, and it is a pleasure to see some of the orchards. The trunks all white with applications of lime to prevent and destroy the pests that are harboured in the next orchards. Trees are being examined, and saw and pruning knife are brought into requisition for the removal of dead and cankered branches. Then, again, young and vigorous plantations are springing up in many localities, and bid fair to give good returns in due time. Such steps in the right direction are by no means uncommon, and many cultivators are realising the importance of the truth—that if fruit is worth growing at all it is worth growing well. Yet the disadvantages are likewise great. Here is a man who takes a pride in his fruit trees; he tries to grow them well, keeps them clean, and endeavours to keep in check the attacks of insect foes. Such a man deserves encouragement, for it is such as he that reap profit out of the occupation. In the next holding, however, may be found a farmer of a different school. Look at his trees, and note the lack of care and labour. They are infested with insects, and no wonder. But this is not the worst, for if he alone suffered he would only be reaping the harvest of dilatoriness. His neighbour, the energetic man, suffers also through the neglect, as the trees which he is endeavouring to keep clean become infested with the insect pests which migrate from the adjoining orchard. This seems hardly fair, and I think I am correct in saying that in Tasmania there is a law which enforces all fruit growers to keep their trees free from insect pests. This is a means of protecting the industrious grower, and perhaps some such power could be vested in the local authorities at home. The matter has already been suggested, and was spoken of at the Conference at the late Crystal Palace Show.

The importance of the fruit-growing question, and attention to even the smallest details, are points which many growers overlook. As an instance a Midland farmer wondered why his neighbour could always get larger and finer Damsons than himself, therefore obtaining a better price, though soil and aspect were the same. He did not even consider the fact that while the liquid which drained from his manure heap ran away, probably to waste, that of his neighbour was carried into the orchard, and applied to the roots—there lay the secret, if such it can be called. Much certainly has

been done to propagate a better system of fruit culture, but it is questionable whether the farming class generally have yet realised the importance of it. Horticultural authorities have done and are doing much to assist the industry, but their efforts do not appear to appeal to the farmer to any appreciable extent. Establish a coalition with agriculture proper; let the two go hand in hand, with one object in view, realising that their interests in this respect are mutual, then may be anticipated a better condition of affairs on the part of a class who seem slow and reluctant to give up what they know to be unsatisfactory.—G. H. H.

THE R.H.S. EXAMINATIONS.

I HAVE no doubt very many young readers of the *Journal of Horticulture* feel very greatly obliged to "A Student" for the answers he is publishing to select questions set at the last May examination. Of the four, which are so excellently answered, three do not properly come within the scope of practical gardening. The one marked No. 1 certainly does, because it relates to the soil and its preparation by digging for the reception of crops. That was a matter well worth greater elaboration; but the other three questions and answers are essentially scientific, and whilst I am very far from deprecating the possession of such knowledge by gardeners, yet I do most certainly think that so long as it is felt desirable to test what may be called "practical" knowledge as well as "study" knowledge, that the two things should be kept separate, and that practical gardening should not be confounded with theoretical knowledge.

At present the questions, in spite of their divisions into grades, are a good deal mixed. The grades, if the term is to be used, should be for theory and for practice. Many students would no doubt like to sit for an examination in the latter, but fear to face the former, because they are not scientific students. I could heartily wish they were; but as they are not, and yet have excellent practical knowledge, why not let their practical knowledge have full play in the purely practical grade, and not seek to handicap it in scientific directions? No doubt there are many young men who, having satisfactorily got through the practical grade, would be induced another year to have a turn at the theory, inspired thereto by their success in the other department. But it would not do to term these grades upper and lower. There is no need whatever to classify them. Let each one have in its marks an equal value.

What we have to remember is that in the making of young gardeners the first consideration must be given to practical knowledge and experience; which no gardener can dispense with or be able to do without. For all ordinary purposes without doubt the purely practical youth is of more value in a garden than is one who is purely scientific, and that would, so regarded, place the practical work higher than the theoretical. But I do not wish to see any such classification. What we need is that the immense value of all knowledge relating to gardening, whether it be of practice or theory, shall be fully realised, and that every encouragement shall be given to all young men training to be gardeners to acquire all such knowledge they very well can. Apart from the usefulness of elementary scientific knowledge there can be no doubt farther that its possession adds greatly increased charm to gardening. But the range of knowledge in gardening is illimitable. It is hardly the young man who realises that; the old ones can and do. The youth who is twenty-five years of age no doubt thinks he knows a great deal, but he will only realise fully how little then he knows when he reaches the age of sixty-five.

Gardening is, perhaps, the most varying and progressive of occupations. Not but that certain great principles which underlie all work remain permanent, but it is in the attributes of gardening that change is so greatly found. Thus the life of the gardening student is not restricted to a few years of youth. It is constant, and indeed ends with life only. Yet the man who has in youth studied diligently, and is armed with good theoretical knowledge, will always find himself in his later life's study well ahead of his fellows.

The worst thing that can happen to any youth in his practice, if he purposes to become a head gardener, is to find his work centred too much in one groove. That sort of thing may be tempting, but it should be resisted. To be constantly amongst Orchids may be pleasant, but it is equally needful to understand all about plant and flower culture and decoration, to have full knowledge of fruit culture indoors and outside, to be equally familiar with vegetable culture in all its varied aspects, to understand soils and their requirements, the planting of trees and shrubs, the laying out of all sorts of gardens, indeed a knowledge of things innumerable. After all knowledge is far from being a bad pecuniary investment in relation to gardening, and that is an aspect worthy of consideration.—A. D.

GLADIOLUS GANDAVENSIS IN 1896.

THE opportunities of seeing this fine autumn flower except in my own garden were not many last season. The discontinuance of their exhibition at the Crystal Palace, to which one was apt to look during many years past, has left a great blank; while that at the Aquarium only offers prizes for a collection, a competition into which it is impossible for the amateur to enter with any hope of success. There remains then, so far as the metropolis is concerned, but the Drill Hall, and here on two occasions very fine collections have been exhibited, but only from the trade. In August Mr. Kelway exhibited a considerable number of spikes, while in September Mr. Burrell showed a grand collection from Cambridge.

I am convinced that the absence of amateur exhibitors is one of the reasons why the flower does not increase in popularity, and no society can be expected to offer prizes for a flower where at the most three growers contend in the amateur class. Those who have noticed our metropolitan exhibitions will recollect that besides myself there were two exhibitors of late years who showed their boxes of twenty-fours in grand style; these were Mr. W. H. Fowler of Taunton and Mr. E. B. Lindsell of Hitchin. Both of them have practically retired, I have been obliged to give up exhibiting, and I really know of no amateur who will step into the vacant places. Were there any prospect of good exhibitions persons might probably come forward, but as this is not the case the one reacts on the other, and the consequence is the present dearth of which we all complain.

I think perhaps that the very excellent seedlings that can now be obtained at a moderate price is another cause. This we know has been the case with other flowers. Very few people now grow named collections of Calceolarias, Cinerarias, or Begonias, as such good flowers can be obtained from seed. Our great growers of the Gladiolus grow a large number of seedlings, and even after they have selected those which they intend to name and place in their list the others are sufficiently good for all decorative purposes, and this is the object which most people aim at in these days. I have had unnamed seedlings this year which did not compare unfavourably with many of the named varieties.

The past season, which has been so perplexing a one to gardeners, whatever the flower they are most interested in, has made its mark on the Gladiolus. The droughty summer was, I think, not unfavourable to the plants; in fact, as their native habitat is South Africa one can quite understand this, and where the soil was retentive they did well. Such a soil as I have often advocated—viz., one that will grow Roses and Strawberries well, will grow Gladioli. As is the case with many other things, it is desirable if possible not to plant them in the same place year after year.

I think great advances are being made in what are called the Lemoinei hybrids. Blue flowers are appearing amongst them, and Mr. Burrell is strongly of opinion that we shall have large and well opened flowers of very striking colours. Some of them are much hardier than others, and I believe that they will stand our winters with a slight protection of coal ashes or cocoa-nut fibre; and although as yet they are not, to my mind, comparable with those of the gandavensis section, but they are very useful as ornamental plants for the garden.—D., Deal.

LÆLIA PRÆSTANS ALBA.

MOST Orchid growers are familiar with *Lælia præstans*, and probably everyone admires its delicate beauty. Many, too, will have seen forms with pure white sepals and petals and a coloured lip, but not all will know the real albino that was staged at the Royal Horticultural Society's meeting, on December 15th, by Mr. H. Holbrook, gardener to E. Ashworth, Esq., Wilmslow, Cheshire. This charming variety was named *L. p. alba* var. Ashworth, and received from the Orchid Committee a first-class certificate. Other than a little pale yellow in the throat the flower is pure white. The specimen staged was a small one carrying one flower only, but it attracted a considerable amount of attention.

MASDEVALLIA TOVARENSIS.

There are few Orchids at once so elegant, useful, and easily grown as this, the only pure white-flowered species in the genus. It would well repay special culture for cut flowers where those of

choice quality are in request, and it is also a charming addition to the Orchid flowering house. As its name implies, it is a native of Tovar, where it grows at a considerable elevation. It may be grown with the coolest section of Orchids through the summer months; indeed all the year round if the winter temperature is kept at or near 50°. This is quite low enough for the Odontoglossums, and the nearer this figure is approached the better for all cool Orchids.

The atmospheric moisture must be ample, frequent dampings being resorted to in bright weather and when fire heat is used. From the end of May until September the house wherein it is grown must be heavily and closely shaded all day long, freely

FIG. 8.—LÆLIA PRÆSTANS ALBA, ASHWORTH'S VAR.

ventilated at night and early morning, and kept rather closer at midday to husband the moisture. During late autumn and winter as much light as possible must be afforded, the glass being kept clean inside and out, and the plants kept well up to it by staging them on inverted pots. Syringing is never required in winter, but during the summer months a light dewing from a fine jet is helpful in keeping the foliage cool and keeping red spider and thrips at bay.

With regard to the roots, these are not so ambitious in pushing far away from the centre of growth as those of many other Orchids, therefore large pots are unnecessary, in fact harmful. Neat little specimens may be grown in the 3-inch or 4-inch sizes, and for the largest plants about 1½ inch of compost around the sides is ample. The latter should consist of two-thirds of clean, freshly gathered sphagnum moss to one of the most fibry portions of peat, plenty of small crocks and broken charcoal being kept at hand for mixing in as repotting proceeds.

Many growers are in the habit of shifting the plants in spring, but for reasons more than once given in these pages I am strongly in favour of repotting in autumn, early enough for them to be re-established before winter. Plants in bad condition must be done at any time of course, as no good, but the reverse, can come of leaving the roots in a close or water-logged compost. The pots must be quite clean, and drained well—nearly two-thirds of their depth—with clean crocks. Cover with moss, and having taken them as carefully as possible out of the old material replant so that the base of the leaves comes a little above the rim, finishing the compost nearly to the usual convex mound. The roots must be carefully watered for a week or two after repotting, and also during winter; but while growing freely in summer a liberal supply is needed.—H. R. R.

EARLY FLOWERS.—How very mild the weather keeps! Primroses and Polyanthes have been in flower outside now for some time, and on Christmas Day and Sunday last my bees were out as though it were a spring day. We have had a quantity of rain, with heavy fogs at times. I hope we may not have to suffer for it later on as regards spring frosts, for so far as I can see there is a good show for fruit blossom round about here.—JOHN GILBERT, Guildford.

DISQUALIFICATION AT SHOWS.

MR. J. MCINTOSH has, on behalf of the Ancient Society of York Florists, sent us a very courteous letter, also a schedule which was provided for the guidance of exhibitors and Judges of the show held at York on November 18th, 19th, and 20th, 1896. Mr. McIntosh states that the schedule was not intentionally withheld, but it was thought that the parties more particularly interested in the discussion would have sent a copy as sustaining their views. The conclusion was a reasonable one, and we accept Mr. McIntosh's statement unconditionally. It is right to add, however, that since our intimation on page 13 last week Mr. Riddell has sent a schedule, with the class marked over which the dispute arose, and the same class is also indicated by Mr. McIntosh. We are quite sure that, as this correspondent states, "the York Society has no desire to conceal anything; nor is it to be conceived that anyone concerned can have any such desire."

We had not thought of making any further reference to the York case at present (in fact we could not usefully do so in the absence of a schedule), but as Mr. McIntosh clearly intimates that the York Society, as well as readers of the *Journal of Horticulture* generally, desire an editorial opinion, the case shall be discussed with the same honesty of conviction which we believe has governed the acts and expressions of all parties immediately concerned.

Mr. McIntosh desires to "point out the main facts bearing on the Society's view of the question," and he does so with accuracy as follows—"In class 63 nine varieties of Apples and six varieties of Pears are simply mentioned" (meaning that any varieties might be staged). Class 60 asks for "three varieties of dessert and three varieties of baking Apples." Class 59, for "six Apples, dessert;" and class 58, "six Apples, baking." It will be seen that our correspondent reads backwards and upwards.

Mr. McIntosh then goes on to say, as he is fully entitled, "We (the Society) maintain that according to custom the Judges were bound to exercise discriminating powers with regard to the varieties exhibited in those classes, except class 63; or they would not be doing justice to exhibitors who were careful to stage nothing but what was in accordance with the wording of the schedule." That is a fair and cogent statement of the case from the Society's view, and it could not well be put more strongly.

It is not in any of those classes over which the dispute arose, but in class 57, thus set forth—"Collection of dessert fruit, six distinct varieties, to consist of two bunches each of two varieties of Grapes, two dishes of Pears, and two dishes of Apples." Mr. J. Riddell included in his collection a dish of Emperor Alexander Apple, and the Judges, as able gardeners and upright men as could be found, "disqualified" the collection, but recommended a grant equal to the second prize, £1. We find no words in the schedule authorising them to do so. Regulation 12 says, "Judges have the power of withholding or diminishing prizes where specimens are considered unworthy, and their decisions shall be final." But here the specimens were admittedly worthy, and because of that the Judges even went beyond the "wording" of the schedule in their desire to do substantial justice to the exhibitor. This is sufficient proof of the genuineness of their intentions.

That they were not within the terms of the schedule is clear from what follows in the same "regulation"—namely, "The Judges may recommend to the Committee extra prizes for collections of decided merit *not specified* in the schedule." The italics are ours; and the specimens which they, in the best spirit, desired to honour were very clearly "specified."

Now as to the finality of the Judges' decision. This did not extend beyond the "withholding of or diminishing prizes." Regulation 13 makes that point clear, for it states, "If any dispute arise notice must be given to the Secretary in writing on the first show day, before 9 o'clock P.M., when the case will be submitted to the Committee, whose decision shall be final." It is not a case of may, but *must*, and if Mr. Riddell did not act in strict conformity with that "regulation" he put himself out of court; if he did so act and the decision went against him, he must accept the verdict of the Committee.

We wish next to say a word on "disqualification." In our experience those judges who do not act at two, three, or half a dozen shows only a year, but at dozens, are exactly those who are the most cautious in writing that (to the exhibitor) humiliating word "disqualified" on a card. They only do so when they have evidence of intention to deceive on the part of a competitor, then they do it in bold letters. When an exhibitor has, by accident or oversight, put himself beyond the conditions, the milder formula is used, "not in accordance with the schedule,"

thus stating a fact without conveying a reproach. They are, indeed, often more lenient still with exhibits, and do what the York schedule enjoins in italics in reference to incorrectly named specimens—namely, "*pass them over without observation*," and leave the showmen (who have not sought to do wrong) to find out the reason why. If an exhibitor is "in accordance with the schedule," whence comes the right of disqualification?

As to the admissibility of the particular Apple in the class above specified, that is, and must be, a question of individual opinion. If a gardener regularly include it, in the discharge of his duty, in a dessert, as we know it has been many times and oft so employed, we cannot say he does any wrong in including a dish of it in a collection of dessert fruits at a show, if not specially excluded. We have seen it included and weaken a collection without causing disqualification, as there was no infringement of the terms of the schedule.

We have previously said that with two lists of Apples only we should place Emperor Alexander in the cooking section; but at the same time, as it is unquestionably employed in desserts, we should not disqualify a collection for containing it if within the conditions, but should "point" it "low" in comparison with superior varieties.

To a greater extent than ever the imposing appearance of fruits is considered an essential element in desserts. Tables have to be made beautiful with fruits as well as with plants and flowers, as leading fruiterers know quite well. Very small Apples and Pears, however good, are relegated to side tables; the delicious Frontignan Grapes have been ousted by the finer-looking but far inferior Alicantes and "Colmans," and the Royal Horticultural Society has condemned the many miserable little Melons seen at shows by imposing a minimum circumference of 15 inches.

It was because of the inclusion of the Apple in question in many desserts, mainly for its beauty, that Dr. Hogg in the last edition of his "Fruit Manual" admitted it as "desirable" on that account on the dinner table; though stating it to be more of a culinary than a dessert fruit. No person living has given so much attention to the subject of fruit, and no one has described so many varieties, their history, and their uses so accurately. It is true that a certain D.D. has gone out of his way, in a contemporary, to indulge in a cheap sneer at the work of the venerable Doctor, who has by sixty years of study and research done something to enlighten even this doctor of divinity, who found his peculiar exercise congenial at this particular time; but it will do no harm—at least to *our* Doctor.

We have consulted Dr. Hogg on this Emperor Alexander case. "It is but an old question," he says, "that has cropped up again because of a case happening to get into print, and any person who regularly uses any fruit in desserts is justified in exhibiting it as a dessert fruit, no matter who may object to it, always provided that it is not rendered ineligible by special conditions, which any society has a right to impose. It then rests with the Judges to estimate its value, but disqualification can only properly follow on some infringement of the terms of the schedule by which an exhibition is governed."

The York Judges did what some other good men would probably have done, but what many others would not. But they acted honestly, with an evident desire not to deal harshly, but the reverse, with a collection they felt bound to disqualify on the grounds stated. They were convinced they were right in their views; the Committee loyally sustained them, and there the matter ends. It is clear that Mr. Riddell had no "intention to deceive," and if the Judges had been acting under the R.H.S. code, they are far too intelligent to have "disqualified" with paragraphs 8 (page 6) and 38 (page 12) before them. But they were bound by neither that nor any code, and exercised their discriminatory and discretionary powers, as evidently desired by the Committee.

Given precise terms of guidance, we know enough of the professional ability and high sense of honour of the Judges in question to enable us to say that we should not hesitate a moment in entrusting any garden produce of ours to their examination and for their decision, and their verdict would be accepted. They (also Mr. Riddell) will have done good service if some definite and authoritative line of action should be formulated as the result of this discussion, and we hope with Mr. McIntosh that such will be the case. Though no harm has been done, as no one believes Mr. Riddell would attempt to do anything wrong, and the desire of the Judges was evidently to do justice, we think the word "disqualified" was rather too strong to use under the circumstances.

We should like to make it clear that we have no reason whatever to suppose if the matter had been submitted to the R.H.S. the decision

would have gone against the York Judges; indeed, we are almost certain it would not without a very sharp struggle, if then, and it will be well if neither side is too confident about being the victor.

APPLES.

CLASSIFICATION.

I QUITE agree with Mr. W. R. Raillem's views (page 13) that there should be three lists of Apples. If we are to have a classification for the guidance of exhibitors, judges, and societies in general, it should be as nearly perfect as it is possible to make it in regard to the respective merits of varieties for dessert and culinary use. This perfection cannot be arrived at with only two lists, as some varieties are equally entitled to be placed in either, and such lists would simply become a dead letter or useless, except when societies accepted them as a standard of authority. The likelihood of all societies accepting such is, I think, very doubtful.

The "select" lists at present in existence serve no useful purpose outside that for which they have been framed, but rather lead to confusion and arbitrary proceedings outside the area of their legitimate influence. If two lists only are compiled, and these generally accepted by societies as a guide to exhibitors, the broad views by which judges should be influenced would be lost, even in cases where the lists had no bearing, by rigidly confining the varieties to their *enforced use*, and consequently irritation would be augmented.

Let the R.H.S. give us something worthy the reputation it bears by tackling the question in its broadest sense instead of merely providing us with special lists for a special purpose. In relegating the respective varieties to certain uses, colour certainly should not be lost sight of in selecting those for dessert, as it equals flavour on the dining-room table; in fact, in private establishments appearance is often more highly prized than quality in dessert. To wit, who would prefer Duchess of Buccleuch to Duke of Buccleuch Grapes on their table? By way of obtaining the general opinion of gardeners on the question of "two" or "three" lists of Apples, I would suggest that the Editor ask all to send him their choice in as few words as possible. If this proposition meet with approval, and is taken advantage of, I would then say take the same means to ascertain the value of colour in dessert. This accomplished, and the facts placed at the disposal of the R.H.S., its members would see what was desired, and guide them in their honourable and responsible office in catering for our requirements.—R. C. H.

[Our correspondent's experience is certainly very great as a provider of dessert fruits for the acceptance of persons of very high rank indeed among our aristocracy. We cannot invite the lists suggested. They would be too voluminous. We are all in favour of something so concise on the subject that it can be inserted as a note occupying about an inch of space in small type in any schedule—e.g., "The following T.K. varieties are eligible (or not eligible) for the dessert classes." A small committee of experts could formulate such list in an hour for the sanction, subject to amendments of a General Committee and the Council of the Royal Horticultural Society.]

ROYAL HORTICULTURAL SOCIETY

DRILL HALL, JANUARY 12TH.

THE first meeting of the year 1897 of the Royal Horticultural Society was held in the Drill Hall on Tuesday, and was an unqualified success. If judgment could be based upon this one meeting a splendid year might be expected, and it is hoped that the augury of the first meeting may be fulfilled. Orchids were, as a whole, of great beauty and fairly diversified, while fruit was well represented. The exhibits before the Floral Committee were not numerous, but of fine quality, especially the Cyclamens from Major Joicey and the fragrant Freesias from N. L. Cohen, Esq.

FRUIT COMMITTEE.—P. Crowley, Esq. (in the chair); with Rev. W. Wilks, and Messrs. G. Bunyard, J. Cheal, T. G. Miles, G. W. Cummins, A. F. Barron, J. Willard, J. H. Veitch, T. J. Saltmarsh, A. Dean, J. A. Laing, W. Bates, G. Woodward, W. Farr, C. Herrin, H. Balderson, G. Wythes, F. Q. Lane, G. H. Sage, G. Reynolds, R. Fife, T. F. Rivers, C. Ross, and J. Wright.

As will be seen, there was a considerable attendance of members, as is usual at the first meeting of the year, but also, as is usual, a limited number of products sent for examination. Mr. John Crook, Forde Abbey, Chard, sent well-coloured fruits of Damelow's Seedling Apple, and a vote of thanks was awarded. A member thought they were good enough for dessert. Messrs. J. Veitch & Sons, Ltd., sent fruits of their Standard Bearer Apple, good size, inclined to be conical, greenish yellow, very firm, good for cooking, and of fair eating quality. The award of merit granted in 1893 was confirmed. Messrs. Veitch also sent specimens of *Belle de Boskoop* Apple, large, flattish, russety, with tender flesh and of good quality. It was thought they had a general resemblance to well-grown fruits of *Hambledon Deux Ans* (award of merit). The same firm further sent *Fraise d'Hoffinger*, a beautiful Apple in appearance, and will probably be grown for exhibition purposes.

Mr. Ward, Stoke Edith, Hereford, sent a seedling Apple like Lady Sudeley in appearance, but inferior in quality. Mr. G. Fulford, West Park, Damersham Gardens, sent fruits of *Doyenné d'Hiver* Pears, very fine specimens of *Easter Beurré*; and a vote of thanks was accorded. Mr. H. J. Sheppard, High Street, Bedford, sent Apple Sheppard's Nonpareil, which was determined to be *Scarlet Nonpareil*.

Mr. G. Wythes sent a box of Tomatoes *Syon Prolific* (Ham Green × Duke of York), very fine and well-coloured fruits; and a cultural commendation was accorded.

Preserved Dates were placed on the table by Mr. J. Wright, as received by him from Lionel Sanders, Esq., one of Her Majesty's Judges in Egypt. Mr. Sanders expressed his surprise that they were not known in England. They are eaten at dessert like preserved ginger, and are very rich, with a distinct and agreeable flavour. A vote of thanks was accorded with an expression of approval of the conserve.

Messrs. G. Bunyard & Co., also Messrs. J. Veitch & Sons, sent extensive and excellent collections of Apples, for which silver-gilt medals were unanimously awarded; and a silver Banksian medal was adjudged to Messrs. Cannell & Sons for a large and excellent assortment of Potatoes.

The Chairman in courteous terms thanked the members for their services during the past year, and those present conveyed unanimous thanks to the Chairman and Secretary for the pleasant and effective manner in which they had discharged their duties, conveying also best wishes for the future.

THE VEITCH PRIZES FOR FLAVOUR.—*Pears.*—Mr. G. Woodward, The Gardens, Barham Court, first with *Winter Nelis*; Mr. Owen Thomas, Royal Gardens, second with *Ne Plus Mearis*. *Apples.*—First prize, Colonel Brymer, Ilslington House, Dorchester, with *Cox's Orange Pippin*; second, Mr. Woodward, gardener to Roger Leigh, Esq., with *Blenheim Pippin*.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. C. T. Drury, H. B. May, H. Herbst, R. Dean, R. Owen, G. Stevens, J. Hudson, J. Jennings, R. B. Lowe, C. E. Pearson, J. Fraser, C. Jeffries, J. T. Bennett-Poë, C. E. Shea, C. Blick, G. Paul, H. S. Leonard, H. Turner, J. Fraser, and J. W. Barr.

Messrs. T. Cripps & Son, Tunbridge Wells, sent specimens of *Hamamelis arborea*, and of *Violet Amiral Avellan*, a good dark single variety. Messrs. W. Cutbush & Son, Highbate, arranged a group of *Cyclamen persicum* flanked by *Ericas melanthera*, *hyemalis superba*, and *hyemalis alba* on the one side, and by *Aucuba japonica vera* in fruit on the other (silver Banksian medal). Messrs. W. Paul & Son, Waltham Cross, sent a large plant of *Crataegus Carrieri*, carrying large numbers of orange red berries of large size. Messrs. J. Veitch & Sons, Chelsea, sent a box of their hybrid *Rhododendrons*.

Mr. F. J. Thorne, gardener to Major J. J. Joicey, Sunningdale Park, Ascot, staged a collection of superb *Cyclamen persicum*. The plants were in 5-inch pots, and were only fifteen months from seed-sowing. The foliage was stout and beautifully marbled, while the flowers were large and of the best colours. Some of the flowers were large, others small, but all perfect in their respective varieties (silver Flora medal). Specimens of a hybrid between *Senecio multiflorus* and the garden *Cineraria* were staged from the Botanic Gardens at Cambridge. The *Cineraria* was strongly in evidence in the colour and size of the flowers.

Mr. J. May, Twickenham, sent a collection of *Cyclamen persicum*, amongst which some splendid varieties were noticeable (silver Flora medal). Messrs. H. Cannell & Sons, Swanley, staged some handsome *Primulas*, including *Eynsford Red*, *Eynsford Yellow*, *White Swan*, *Swanley Blue*, *The Queen*, *Cannell's Pink*, and several others in fine form (silver Flora medal). Mr. A. Sturt, gardener to N. N. Cohen, Esq., Englefield Green, sent a group of *Freesias*. The plants were splendidly grown and profusely flowered (silver Flora medal).

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, T. W. Bond, D. B. Crawshaw, R. B. White, H. M. Pollett, H. Ballantine, F. Hardy, J. T. Gabriel, G. W. L. Schofield, W. H. White, W. H. Young, H. J. Chapman, E. Hill, J. Jacques, W. Cobb, J. Douglas, and S. Courtauld.

Messrs. F. Sander & Co., St. Albans, arranged a bright exhibit of Orchids, amongst which the most conspicuous were *Odontoglossum Harryanum*, *O. Rossi majus*, *Lycastes*, and *Dendrobiums*. Mr. H. Ballantine, gardener to Baron Schöder, The Dell, Egham, exhibited a few Orchids of magnificent quality, and in the best of health (silver Flora medal). Messrs. J. Veitch & Sons, Limited, Royal Exotic Nursery, Chelsea, signalled the first meeting of the new year by arranging some splendid Orchids, comprising *Laelio-Cattleyas*, *Cypripediums*, *Epidendrum elegantulum*, and several others (silver Flora medal).

F. Hardy, Esq., Ashton-on-Mersey, staged a few Orchids, conspicuous more for quality than for quantity. Messrs. H. Low & Co., Clapton, staged a few Orchids (silver Flora medal). Mr. W. H. Young, Orchid grower to Sir F. Wigan, East Sheen, sent some varieties of *Laelia autumnalis* and a spike of *Cymbidium grandiflorum*. Mr. W. H. Lees, gardener to F. A. Bevan, Esq., Trent Park, Barnet, arranged a strikingly beautiful collection of *Odontoglossum crispum* and *Pescatorei*; the plants were grandly grown and staged (silver Flora medal).

CERTIFICATES AND AWARDS OF MERIT.

Cattleya Loddigesi superba (H. Ballantine).—A beautiful form with rose coloured flowers (award of merit).

Cyclamen papilio (De Laughe).—The flowers of this are variously coloured, and are somewhat flat with fimbriated edges (award of merit).

Cypripedium Lebaudyannum (L. Linden).—A long wavy petalled hybrid; colour green at the base, with brown spots, and brown at the extremities. The dorsal sepal is pale green, striped and spotted brown. The pouch is green, flushed brown (award of merit).

Cypripedium Lilian Greenwood (H. Greenwood).—The petals of this are claret with chocolate spots, the dorsal sepal being of the same shade, with the spots at the base. The pouch is claret red (award of merit).

Lælia Lucy Ingram (T. W. Bond).—A hybrid between *L. purpurata* and *L. Perrini*. The sepals are pure white, the petals delicate rose, and the lip rich maroon (award of merit).

Mormodes labium luteum (E. Hill).—Pure yellow, as inferred by the name, is the colour of this variety (award of merit).

YELLOW MADAME CARNOT—SIMULTANEITY AND REVERSION.

THERE are now three yellow sports from this variety—Wells' sport, No. 1; Jones' sport, No. 2; and Owen's sport, No. 3. All originated during the same month and the same year, in three different localities. They have all three flowered and shown a decided yellow shade. The one I am in possession of I mean to thoroughly prove before offering it to the public at any price. Should I have to refund, as in the case of White Vivand Morel and two others I could name, growers would fight shy of me in future. I have known, after two and three years' trial and careful selection of cuttings to fix the sport, a great portion of the stock to revert. The plant that produced Mrs. S. Coleman produced Princess of Wales, Miss Haggas, Matthew Russell, and Mrs. Heale, all in the same year and from same rootstock. What may we expect from the three sports during 1897? George Haigh, sport from Robert Petfield (the latter a seedling from Princess of Wales) reverted in several places after two years' trial. Again, Lord Alcester has reverted with me, and produced the whole of the Queen family bar the bronze sport. Such freaks are enough to make one cautious.—ROBT. OWEN.

BIG CHRYSANTHEMUMS.

THE *Gardeners' Magazine* says, "We have heard many complaints of the large size of the Chrysanthemum blooms shown in London, and at Hull, Birmingham, Edinburgh, and other centres, during the past season; but it would appear that these blooms were mere pigmies as compared with those exhibited at one of the smaller towns in Scotland. A correspondent sends us a cutting from a Scottish paper of a few weeks since, in which appeared a report of the Chrysanthemum show held at Kilmarnock, and asks whether we have seen blooms equal to those which the reporter states were exhibited there, and we have to confess that we have not. 'The exhibition,' we are told, 'was of excellent quality, and excelled any previously held by the Society;' and this we can readily believe. We are also informed that 'in the gardeners' classes for pot plants the principal prizes were won by Mr. Andrew Kerr, Bellfield, some of whose blooms measured 5 feet across.' We have, unfortunately, no information with regard to the dimensions of the plants, or the pots in which they are grown; or of the varieties they represented. We are also left in some doubt as to whether the blooms which 'measured 5 feet across,' borne by Mr. Kerr's plants, were the largest in the show, for 'in the class of eighteen blooms, Japanese Chrysanthemums, twelve varieties, remarkable for colour, size, and height of bloom,' Mr. Kerr only succeeded in obtaining second place. We are sorry these remarkable specimens were not shown on the occasion of the N.C.S. Jubilee, and trust that we shall have an opportunity of seeing the next plants with blooms that measure '5 feet across.'"

THE N.C.S. JUDGES.

"A MEMBER of the N.C.S." does not write in a spirit of fair play when he adduces spite and vindictiveness as the motive for my calling attention to the judging of the principal classes at the second exhibition (November 5th) of the N.C.S. I am well aware of the fact that it is very easy to criticise other men's work, and judges of Chrysanthemums oftentimes get their share of criticism. I have no patience with the disappointed exhibitor who will make a fuss over nothing.

Had "A Member of the N.C.S." been in the vicinity of the principal class for incurved he would have given me credit for something more than "spite and vindictiveness." Scores of the best exhibition growers of the day, including friends of the Judges, protested against the awards, many stating that "the bad judging was apparent yards away from the blooms." To show that I am not alone in a protest, an editorial note to my previous letter informs us that others had written on the matter, but too strongly for publication. Again, did not some of the press reports inform us that the awards did not give general satisfaction?

"A Member of the N.C.S.," whilst admitting that trade growers should not judge in classes in which any blooms they may have special interest in are shown, points to the National Rose and other societies as having trade judges, as if that makes what he thinks is wrong to be right. These societies have nothing to do with the question, but I contend that if a trade grower puts plants into the hands of an expert to grow, and the said trade grower holds the entire stock of the variety, which is yet undistributed, he is naturally desirous that this variety should have prominence in a first prize stand—in fact, he has more monetary interest in the exhibit than the exhibitor himself. I do not suggest he would knowingly do what is wrong; on the contrary, I will give him

credit for doing what he feels to be exactly right; but, all the same, he is placed in an unpleasant position, and such as numbers of persons think he ought not to be called upon to occupy.

Will "A Member of the N.C.S." inform us when such a case has been known of a trade judge officiating in classes in which his own new varieties were included at exhibitions of other floral societies? I am taken to task for singling out the N.C.S. for the criticism in respect to the appointing of judges. There is no need to select so many judges from the Committee, for there are plenty of equally good growers outside of the Committee as there are in it; and when all the Chrysanthemum world is taking interest in the champion classes, no opportunity should be given for anyone to say that any of the judges had the slightest interest in any of the exhibits. If my critic think they may have such interest, and that the principle is sound, let him say so. It will be better than attributing "spite and vindictiveness" to one whose motives may even be as pure as his own.—FAIR PLAY.

NEW CHRYSANTHEMUMS—DECORATIVE VARIETIES.

(Concluded from page 5.)

CULTIVATORS are recognising the value of this section. Beautiful as are the large exhibition blooms, the smaller flowering graceful types are really more valuable to the decorator. The following new varieties are deserving of attention:—

Surprise.—This is an October flowering variety of the richest plum purple in colour. The florets are narrow, reflexed, and drooping.

Golden Ball.—Known also as Golden Elsie. It is a sport from the primrose coloured Elsie, having all the characteristics of that free-growing and flowering variety. Golden yellow in colour.

SINGLE FLOWERED VARIETIES.

So popular have the free flowering types of single Chrysanthemums become that any addition possessing merit is eagerly sought after. The following I can recommend, having noted them during a tour of the shows in various parts.

Jenny Wren.—The reflexing florets are semi-drooping, rich chocolate purple in colour, graceful in form.

Alphonso.—This is blush white, and the flowers are large.

Miss M. Rennie.—Cinnamon is the ground colour, which is flushed with bronze.

Rose Pink.—As the name implies, the colour of this is a rosy pink; excellent.

Sarah Wells.—The narrow florets of this variety are somewhat open; rosy white.

Miss Brown.—Yellow, flushed, spotted, and striped with crimson is the colour of this.

Snowdrift.—As its name implies, this is pure white, beautiful in shape of floret; a graceful semi-drooping variety.

Ewan Cameron.—A blush white with broad, semi-drooping florets.

Mary Williams.—This is related to Admiral Sir T. Symonds, judging from the style of flower. The colour is yellow, edged red.—E. MOLYNEUX.

A FEW SCRAPPY CHRYSANTHEMUM NOTES.

I FIND there are a few persons not so far "gone" in the craze for bigness as to worship at the feet of that great idol—"size." With the exhibitor everything else seems to be cast on one side for "size," and whatever new variety is placed before the critics, it may possess all the attributes of beauty, may be of the most refined shape, display colours the most tender in various shades harmoniously mingled; these and every other merit you can mention are all cast away to the four corners of the earth if not built up to the magnitude of the idol—"size." Is this as it should be?

Mr. Molyneux's annual selection. I look for this with unabated interest, carefully noting his remarks for comparing with my own, and only feel disappointed when at the bottom I see "To be continued." He is too far away for us to shout to him, as is sometimes done to a public speaker, "Go on," so we must anxiously wait for the next edition.

But to go on. "S., Yorks," and "W. S., Wilts," have drawn out my pen, for I am of the opinion that far too little attention is given to the decorative class of Chrysanthemums, and I feel that many varieties of the most exquisite form are swept under that "Juggernaut car"—"size." I quite endorse all that is said about Niveus as being a real gem for late cutting. Mdlle. Thérèse Rey is very good white, but too weak in the stem. No mention is made of the sturdy grower Princess Victoria, creamy white, a grand variety for cut flowers at Christmas or after. Potter Palmer, a pure white, of large size, is also late, and of good habit. New Year's Gift is another large white, with long broad florets of good form, coming in as its name indicates with the new year.

Leon Frache is certainly a very good pink, but one of later introduction will come to the front as soon as its merits as a late bloomer are better known—viz., Madame Felix Perrin, a soft rose, free grower, and erect flowers. I can recommend to "W. S., Wilts," a good dark sort for Christmas—viz., Elmer D. Smith, a rich deep crimson, not half enough known. L. Canning was condemned by me, but following "W. S.'s" hint it will now get reprieve for one year to see how second-year plants succeed.

Madame Carnot for market is a gem, and has a good companion in Mdlle. M. A. de Galbert, pure white. Souvenir de Petite Amie is no doubt the "beau idéal" of a decorative or market plant. Simplicity, of recent introduction, a pure white, extra large flower, in the way of Niveus, of

dwarf habit, will become popular in the near future for either exhibition or decoration. Emily Silsbury, pure white, a very easy grower, is already receiving the attention of market growers, but is rather early. Lady Byron and Lady Esther Smith, both pure white, new last year, are also being grown largely. Surely here we have plenty of whites; but if Baron A. de Rothschild does not prove a useful market variety I—but stop. I am only a "probationer," and my article will have to be

FIG. 9.—MONS. ERNEST FIERENS.

"deleted" I fear. However, I venture to pass on to the yellows and others.

Golden Gate is a splendid variety for Christmas blooms. Thomas Wilkins is very good, but if you want a bronzy shade try E. G. Hill, which is a good late. Tuxedo is a grand orange, a strong grower, coming in December and January. For a bright yellow nothing can yet compare with W. H. Lincoln. Wilfred Marshall is a fine bold flower of a lemon yellow tinge. Of newer varieties Edith Tabor, canary yellow, must become a favourite for market. Australian Gold has also the habit of growth required for market work, and Modesto is without doubt the most brilliant yellow in existence, a good grower, and sturdy habit, meeting every requirement in a decorative plant.

Well, Mr. Editor, there are a few more I should have liked to say a word for, which you will see in the box of blooms sent to you. Those exhibition chaps have had all the say in our paper for some months, but their big game is all slaughtered now, and their monster idols in the dust, so such like as your humble scribe can possibly come in with a few late blooms.—T. G., Devon.

[Devon is not considered a cold late county, and Devonians have done, are doing, and will do, good service in the floral world. Though the weather has been mild, if not "balmy," of late in the West, this free lance has evidently no lack of pure and bright Chrysanthemums, or he could not have sent us about forty blooms in fifteen varieties—mostly yellows, but one golden bronze, his favourite, E. G. Hill, highly effective. The purer and pale yellows include Charles Blick, rich; Owen Thomas, fine; Wilfred Marshall, attractive; Duchess of Wellington, Le Prince de Bois, Duchess of York, Challenge, Jeanette Sheeham, pale; and Philadelphia, sulphur. Blush-tinted are represented by Louise, Princess May, and Madame Calvat, and whites by Madame Alfred Chatin and Miss Maréchaux. Now the "pen is drawn" it can run on, and the "chap" behind it need not trouble himself about "deletion."]

A TOUR ABROAD BY A HAPPY TRIO.

(Continued from page 3.)

THE steamer drew up to the side of the Ostend quay, the captain shouted his orders in what I took to be Flemish, the seamen holloed, and the passengers soon began to crowd round the gangway preparatory to disembarking. Fortunately I had made friends with the steward, and had discovered he was a Ghent man. He was delighted to be of service to us, finding we were on the way to his native city, and without more ado he set off and brought us a couple of porters to land our boxes and see them into the train for us. But this was easier said than done. A tall, heavily built official put the usual question that first strikes the foreigner's ear, *Avez-vous quelque chose à déclarer?* which being interpreted means, Are you a smuggler? and then we knew we were face to face with the Customs House Officer. The flower boxes were objects of mystery. I explained they only contained cut flowers for the grand Chrysanthemum show at Ghent on the following day. He seemed dubious, as if Chrysanthemum leaves were used for cigar making, and finally our flower boxes had to be ruthlessly broken open where the lids did not give easily, and inspection allowed. I found he was searching for phylloxera, but as the blooms had no roots the boxes were passed, fastened up afresh, and put in the carriage.

This interesting performance took place about three o'clock in the morning, and a raw, uncomfortable morning it was. Having a quarter of an hour or so to wait before the train started, we had a cup of hot coffee, and then started off. Then we stopped, and I could not help thinking of the Dean of Rochester's funny story about a cow on the line. But we ultimately did arrive at Ghent a little before 5 A.M.

We got outside Ghent station at the earliest possible moment, and the porter called a cab, and when we found the driver was none other than Honorez—genial, buxom old Honorez, the English-speaking cabby who acts as guide, philosopher, friend and interpreter to so many English and American visitors—our joy was unbounded. Gentle reader, if you have been to Ghent you know his "gee-gee." Everybody does; it is so wonderfully and fearfully made, but it can travel and whisk round corners in a way that is positively alarming to a tired, timid

traveller. And the cab! A splendid vehicle, and Honorez's own property; but the only fault a tall man can find is that it ought to have a sliding roof, that is, of course, when there is no luggage on the top. A few minutes brought us to the door of the Hotel de la Poste, and after a little rest came down to breakfast fresh as Daisies. Honorez, true to the tick of time, was awaiting us, and we reached the Casino in safety, and with a long-drawn sigh of relief I saw those boxes of flowers carried into the exhibition hall. A hearty welcome awaited us. Mons. Ernest Fierens (fig. 9), the Secretary of the Society, came forward in his usual genial manner to greet us and to make such introductions as were needful; the Comte Kerchove de Denterghem, Mons. de Meulenaere (fig. 10), his son, Mons. Ed. Pynaert and his son, Mons. Van Houtte, Mons. Van Hal, Mons. Stepman, and many others whom I already knew, being already on the spot. We soon explained the object of our coming with so much luggage, and the greatest facilities were offered for the effective arrangement of our trophies. Mr. Jones and Mr. Bevan being practical men, were soon busily arranging the blooms, and as there was a good run of tabling provided for the exhibits, they were ere long placed in the glass bottles provided, then labelled and placed in position.

The flowers staged in the name of the N.C.S. consisted of some grown by the following members—viz., Messrs. Brookes, Turk, Martin, Skeggs, Sandford, Jukes, Bevan, and Page, and formed a good representative collection of the different sections. The grand Madame Carnot, which was grown by Mr. Page, was particularly conspicuous, and specially mentioned by the jury, while the entire exhibit (the first of its kind shown in the name of the N.C.S.) was awarded a silver-gilt medal *encadrée*—one of the prettiest things I know, being an ordinary medal of the Royal Agricultural and Botanical Society of Ghent set in a Laurel wreath bordering with a ring attached, and measuring altogether 2½ inches in diameter. The inscription is as follows:—"Awarded to the National Chrysanthemum Society of London for a group of cut Chrysanthemums, November 15th, 1896." Messrs. Cannell & Sons of Swanley also contributed a collection of cut blooms, as did Mr. Jones. Both of these exhibitors were awarded a similar prize.

The work of judging is not left in the hands of one or two persons, as is customary in England; but a jury, as it is called, is appointed, consisting of a large number of gentlemen, and these not actual residents in Ghent. Besides Chrysanthemums there was a large display of Palms, Ferns, foliage, and other decorative plants, and these with the Chrysanthemums displayed with exquisite taste, and I certainly think that some of our organisers of shows would do well to run over to Ghent one November and see for themselves what is possible to be done and how to do it in the way of picturesque arrangement.

Before commencing operations each member of the first section of the jury, of which I had the honour to be appointed President, was supplied with a copy of the schedule and of Mr. de Meulenaere's excellent Chrysanthemum catalogue for reference. This gentleman, besides being a most enthusiastic amateur cultivator and a large exhibitor of finely grown Chrysanthemums at the Ghent exhibitions, is also a literary worker of international repute. His catalogue of Chrysanthemums and subsequent supplements are monuments of patient, untiring, and trustworthy zeal, and contain very much information of a detail nature, such as dates of introduction into commerce and raisers' names, which cannot be obtained from any other source, and which have been officially recognised both by the Society at Ghent and by our own N.C.S. here in London.—C. HARMAN PAYNE.

FIG. 10.—MONS. O. DE MEULENAERE.

(To be continued.)

THE CLEMATIS DISEASE.—Many Clematis growers unfortunately know that the beautiful variety Jackmanni is liable to die off suddenly by an attack of fungus near the root, which sends its ferment through the whole upper portion in precisely the same manner that fire blight does in trees. This seems to occur more frequently when the plants are about one or two years old. It would be very interesting to know whether anyone who has a plant older than three years that has suffered. If it be a fact that the disease is entirely confined to these young plants it would be encouraging to lovers of this fine flower to replant when one has died. There is scarcely anything more beautiful than this variety of Clematis, and many growers would not mind planting a few times, if they felt sure that after reaching a certain age the plant would have immunity.—("Meehan's Monthly.")

WEATHER IN LONDON.—Rain has fallen every day for the past week, though not always heavily. From Thursday to Sunday there was an almost incessant downpour, which led to the flooding of several houses in the low-lying suburbs of South-west London. Neither on Monday, Tuesday, nor Wednesday of this week was the rain so heavy, but it fell at frequently recurring intervals.

— **THE LATE MR. A. WATERER.**—The personal estate has been valued at £128,736 6s. 11d. of Mr. Anthony Waterer of Knaphill Nursery, Horsell, Surrey, nurseryman, who died on November 16th last, aged seventy-four years. Probate of the late Mr. Waterer's will, which bears date February 5th, 1895, has been granted to his son, Mr. Anthony Waterer, to whom the testator left all his real and personal estate absolutely.

— **BUTTONHOLES AND 'BACCA.**—A provincial florist, seedsman, and nurseryman describes as follows his method of trade association and expansion:—"I am making my business more profitable than ever. I bought a tobacco business, and the two work well—buttonholes and cigars. I think the seedsmen and florists will have to mix a little, for with fishmongers and ironmongers selling flowers, chemists selling seeds, and wholesale houses selling retail, it requires seedsmen and florists to do a little thinking and return the compliment, which in my case pays."

— **A FINE HOLLY.**—While passing on the high road from Sandwich to Canterbury the other day my attention was directed to the finest specimen of berried Holly I have ever seen. The tree, which was growing in the little front garden of an old-fashioned cottage by the wayside, was conical in shape, with a bare stem of about 5 feet from the ground. The tree has evidently been kept carefully trimmed, as it was of perfect shape, tapering away to a point at the top. Without the berries there would have been nothing particularly noticeable about it, but so thickly were these clustered all round the tree, and so brilliantly scarlet were they in colour, that one could not help stopping to admire the specimen. In the sunlight the berries, which were of extraordinary size, seemed to flash with an exceptional brightness, and never before have I seen anything so beautiful in the shape of a common Holly.—H.

— **LUCULIA GRATISSIMA.**—While passing through the flowering house at Kew a few weeks ago I was struck with the beauty of a large specimen of this old-fashioned flowering shrub. One rarely meets with it nowadays, yet what could be more charming in the dead of winter than a plant covered with its delicately tinted trusses? Here we have its chief qualification. Summer-blooming shrubs are plentiful enough, but in the *Luculia* we have one that comes in at a time when flowers are scarce. For conservatories and other houses where it may be permanently planted it is well suited, and it seems a pity that such a well-tried shrub is not more largely grown. Flowers for winter is the never ceasing cry, and yet this is only one of the many that could be mentioned, which if grown would fill a void too often noticeable.—G.

— **RATING OF GLASS HOUSES.**—An important appeal affecting the position of market gardeners under the Agricultural Rates Bill of last session has been heard at West Sussex Sessions. At Worthing there are about sixty market gardeners who grow Tomatoes, Grapes, and other produce for market under glass. The overseers had returned these holdings as market gardens, and therefore subject under the Act to a deduction of half the rates. The local surveyor of taxes declined to accept them as market gardens, and the Union Assessment Committee upheld him, on which this appeal was lodged. The appeal was defended by the Board of Inland Revenue, on whose behalf counsel contended that the Agricultural Rates Act, which was passed for the benefit of distressed agriculture, expressly exempted agricultural buildings from its operation, and that the glass houses in which the appellants' fruit was grown were buildings within the meaning of the Act, and therefore not liable to any relief from taxation. The court, however, upheld the appeal, with costs.

— **CARDIFF GARDENERS' ASSOCIATION.**—The opening meeting of the 1897 session was held on Tuesday, January 5th, in the Temperance Club. Alfred Thomas, Esq., M.P., the President, occupied the chair, when Mr. W. W. Pettigrew gave a lecture on the "Process of Fertilisation," illustrated by limelight. This lecture also opened a botany class in connection with the Society. The lecturer was closely followed by all present, who numbered between sixty and seventy members, of whom twenty-four joined the class.

— **DEVON AND EXETER GARDENERS' ASSOCIATION, SPRING PROGRAMME.**—January 20th, Mr. R. Hodder, "Manures for Garden Soils." February 3rd, Mr. J. Mayne, "The Forcing of Seakale, Asparagus, and other Vegetables." February 17th, Mr. Thos. Brockbank, "Orchids and their Cultivation." March 3rd, Mr. J. Weeks, "Cinerarias and Primulas." March 17th, Hyacinth and general spring show; entries close 13th March; schedules on application. March 31st, Mr. Fred C. Smale, "Flower Shows—Past, Present, and Future."

— **TORQUAY DISTRICT GARDENERS' ASSOCIATION.**—The members of the above Association held their fifth annual dinner on the 6th inst. at Giles' Exeter Hotel, Torquay. About seventy sat down, Dr. R. Hamilton Ramsay presiding, and Mr. W. B. Smale occupying the vice-chair. Commander A. S. Phillpotts, R.N., M.P., was also present. Toasts were given, and an excellent musical programme, arranged by Mr. W. A. Masterman, was carried out. A most enjoyable evening was spent. The general arrangements were made by Mr. F. C. Smale (Hon. Secretary), and the tables were beautifully decorated with plants and cut flowers by Messrs. F. Peacock and S. Vallance.

— **ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.**—The annual meeting of this Association was held at Warburton's Hotel, Newport, on Saturday, January 9th, when there was a large attendance of members present. The balance sheet and report were adopted. The former showed the Association to be in a good financial condition, whilst the report gave a favourable account of the work done by the Association, from a gardener's point of view. Mr. J. Merritt, gardener to H.R.H. Princess Beatrice, Osborne Cottage, I.W., staged fine collections of Princess of Wales and Princess Beatrice Violets. Several of the individual blooms measured close upon 1½ inch in diameter. For this excellent exhibit Mr. Merritt received the Association's certificate of cultural merit. Mr. W. Matthews, of Carisbrooke Cemetery, staged a fine *Chrysanthemum* bloom of Mrs. C. E. Shea. The next lecture is on February 6th, when Mr. H. J. Jones, of Lewisham, will be the lecturer on "*Chrysanthemums*." —S. HEATON.

— **WAKEFIELD PAXTON SOCIETY.**—There was a large attendance at the meeting on Saturday, January 2nd, Lieutenant Goodyear presiding, and Mr. J. G. Brown being in the vice-chair. Mr. G. Parkin, President of the Wakefield Naturalists' Society, was the essayist, and his subject was "A Chat about Small Birds—Finches," and his remarks were illustrated by a large number of beautifully preserved specimens, and also by photos of nests. A discussion followed Mr. Parkin's discourse. Mr. Eastwood, Stanley, suggested the provision of an aviary in the Public Park, saying it would be a great attraction, and be the means of cultivating the study of birds. The Chairman thought the suggestion of Mr. Eastwood a valuable one. The Government Inspectors deprecated the exhibition of stuffed specimens in elementary schools, and as it was almost impossible for town children to see many of the birds common to the district alive, an aviary was just the thing which was needed in a public park. Several other members agreed with the suggestion, and thought it one which was well worth consideration by the Park Trustees. A cordial vote of thanks was given to Mr. Parkin.

— **THE PHYSIC GARDEN AT CHELSEA.**—This is well-nigh the sole remnant of picturesque old Chelsea left untouched by the brick and mortar fiend. As far as its original purpose goes it has long been useless, although kept up carefully by the Apothecaries' Company. Should the Company give up its charge it will fall into the hands of Earl Cadogan. Its value as a site for building purposes is obvious, but it would be a thousand pities for this, the last of many old English botanic gardens, to be lost to posterity. The names of Sloane, Banks, Linnæus, Miller, and Lindley are all inseparably connected with it, and it is full of plants that are aristocrats of their kind, since they possess a pedigree dating back to the days when their ancestors were first introduced to this country. A contemporary learns that a project for acquiring this spot of many memories is again before the local authorities.

— ADULTERANTS OF VEGETABLE SUBSTANCES.—The Röntgen rays have been employed with good effect by Dr. F. Ranwez in the detection of mineral matters used in the adulteration of saffron. The chief adulterants are barium and potassium nitrate, which in some instances are largely used. His plan, says a contemporary, was to wrap a gelatino-bromide plate in black paper, place the saffron on this, on the same side as the sensitive film, then allow the rays to act for four minutes; developing and fixing afterwards in the usual manner. The foreign matter is sharply indicated in photographs obtained.

— ROYAL METEOROLOGICAL SOCIETY.—The annual general meeting of the Society will be held at 25, Great George Street, Westminster, on Wednesday, the 20th instant, at 7.45 P.M., when the report of the Council will be read, the election of officers and Council for the ensuing year will take place, and the President (Mr. E. Mawley, F.R.H.S.) will deliver an address on "Shade Temperature," which will be illustrated by lantern slides. The above meeting will be preceded by an ordinary meeting, which will commence at 7.30 P.M.

— WEATHER IN THE NORTH.—For a week the weather has been generally dull and cold, with occasional high winds during the night. Saturday was extremely unpleasant, gleams of sunshine alternating with snow showers driving before a biting east wind. There were 5° of frost during the night; Monday afternoon and evening were wet; Tuesday morning misty and cold. The Aconite and Snowdrop are in bloom, Crocuses and Daffodils well above ground, and stage Auriculas are beginning to move, while Violas, white and yellow, have been in continuous flower.—B. D., *S. Perthshire*.

— THE WEATHER LAST MONTH.—December was dull, damp, and milder than usual. The wind was in a southerly direction twenty-two days. Total rainfall, 3.30 inches, which fell on twenty-four days; the greatest daily fall being 0.65 inch on the 4th. Barometer, highest reading, 30.064 on the 27th at 9 P.M.; lowest, 28.468 on the 6th at 1 P.M. Thermometers, highest in the shade, 52° on the 26th; lowest, 25° on the 16th and 24th. Mean of daily maxima, 42.35°; mean of daily minima, 33.35°. Mean temperature of the month, 37.85°; lowest on the grass, 20° on the 16th and 24th; highest in the sun, 79° on the 8th; mean of earth at 3 feet, 40.96°. Total sunshine, 40 hours 55 minutes. There were fifteen sunless days.—W. H. DIVERS, *Grantham*.

— FREE HORTICULTURAL LIBRARY.—We learn that the Corporation of Worthing has recently opened a free library in which the books of horticultural interest which have been got together form a most important and special feature. The commendable action of Worthing in thus recognising the value of horticulture is a most happy venture, and we trust is an example that will soon be followed by other corporations. The majority of our public libraries are very deficient in horticultural literature, in spite of the fact that it is to horticulture that we have to look for assistance in solving that great problem of how to feed the people.

— MIMULUSES.—The beautiful so-called Monkey Flowers, of which there are now such fine strains, self and spotted, are far too seldom found in gardens. Perhaps it will be pleaded in extenuation by gardeners that they cannot grow everything, and that is very true; still farther, such is the demand for flowers that can be used in a cut state, that many beautiful things unsuitable for cutting are neglected. Certainly the spotted *Mimulus* is amongst these little-grown plants, yet its culture is simple, and the flowers produced in the open garden, where the plants may be grown, are really gorgeously coloured and beautiful. *Mimuluses* are very hardy, although not absolutely so, and like cool treatment. Too often at the outset the seed is sown in warmth, and too densely; then the seedlings rapidly become drawn or weak, and rarely indeed do they make presentable plants. My own practice for many years was to sow the seed thinly in shallow pans and on fine sandy soil. This was done early in January, and in an unheated greenhouse. If severe frost came the pans were protected by the aid of newspaper coverings. Still, so hardy relatively are the seedling plants, that frosts did them little or no harm. So soon as large enough the little plants were lifted and pricked out thinly into other pans or boxes, where they would remain a few weeks; then be planted out into a cold frame near the glass, getting ample light and air. Towards the end of April, being well hardened, they were transplanted outdoors about 10 inches apart, where they made dense bushy plants, and bloomed profusely during the early summer, and then outdoors again in the autumn. *Mimuluses* seed freely, the seed being very small. The chief danger in sowing is excessive thickness. It germinates very readily in a low temperature.—A. D.

— DEATH OF MR. J. WEBBER.—We regret to have to announce the death of this well-known Covent Garden salesman, which occurred on the 4th inst. Mr. Webber's establishment in the Central Avenue is one of the oldest in the market, having been carried on originally by his father, and at his death by his mother, in conjunction with Mr. Tayler. The deceased was in his fifty-sixth year.

— ROYAL GARDENERS' ORPHAN FUND.—A meeting of the Executive Committee was held on the 8th inst., Wm. Marshall, Esq., in the chair. Applications were received from thirteen candidates to be placed on the Fund at the next election, and these being found eligible were duly accepted. The Committee, in consideration of this being the sixtieth year of Her Majesty's reign, and the Fund having been established by the gardeners of this country in commemoration of Her Majesty's Jubilee, have resolved to recommend to the subscribers that the whole of the candidates be elected (without ballot) at the next annual meeting, on February 19th. It has been arranged that the annual dinner be held this year at the Hotel Cecil on April 30th, Sir J. Whittaker Ellis, Bart., presiding. The following receipts were announced by the Secretary, the donors being specially thanked—The Altrincham Gardeners' Mutual Improvement Society (proceeds of concert), £30 10s.; H. J. Jones, Lewisham, £10 15s.; Reigate Chrysanthemum Society, £10; Scottish Horticultural Association, £5 5s.; J. H. Vallance (sale of flowers at Bristol Chrysanthemum show), £5 5s.; J. B. Stevenson, Bournemouth (box), £1 9s. 5d.; J. Day, Galloway, Garlieston (box), £1 1s.

— GRAND YORKSHIRE GALA.—On the 8th inst. the annual meeting of the guarantors and life members of the Grand Yorkshire Gala was held at Harker's Hotel, York. In the absence of Ald. Sir Joseph Terry, J.P. (the Chairman of the Council), the Lord Mayor (President of the Gala) took the chair, and there was a good attendance. Upon the result of last year's Gala, he said that those associated with the fête had every reason to congratulate themselves. It had proved one of their most successful ventures. Had the weather been fine on the opening day, the gala might have been a record one. As it was there had been some extraordinary expenses, so that a most favourable balance had been somewhat diminished. They were, however, prepared with a schedule of £750 for the ensuing year, which amount he believed was as large as that offered by any horticultural society in the country. Ald. Border proposed the re-election of Sir Joseph Terry as Chairman of the Council for the ensuing year, and alluded to his long connection with the fête. Mr. George Kirby seconded the proposition, which was unanimously agreed to. The President moved the election of Ald. Border as Vice-Chairman. Mr. Henry Scott seconded, which was assented to *nem. con.* The President announced that satisfactory arrangements had been made with the Bootham Asylum authorities for the holding of the fête in June next, whilst he again consented to act as President, and the City Sheriff (Ald. Dodsworth) had agreed to become a life member. Mr. Joseph Wilkinson was re-elected Treasurer, Mr. C. W. Simmons Secretary, and Messrs. Pearson and Taylor Auditors.

— SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.—The members of this Society held their eighth anniversary dinner at the Imperial Restaurant, Strand, on Saturday evening last, and it was probably the most successful one that has yet been held. Mr. George Nicholson, Kew, occupied the chair, and he was supported by several representatives of English horticulture. The proceedings were almost wholly in French, and in introducing the Chairman to the assembled company Mr. George Schneider, as President of the Society, reminded them of the great interest Mr. Nicholson had always taken in the welfare of the Society and of its members, for he, like them, knew what it was to live in a foreign land, in order to gain experience and complete his horticultural education. Mr. Nicholson responded in well chosen and appropriate terms, complimenting the Society on the good work it was doing, and referring to the substantial progress, as evidenced by their balance-sheet, that the Society had made. He also paid a tribute of respect to their excellent President, Mr. Schneider, for the way in which he had fulfilled that post, and he drank to the continued prosperity of the Society. Mr. Schneider returned thanks on behalf of himself, and was pleased to find the Society meeting with the support of English horticulturists. Other speeches were made by Mr. C. Harman Payne, Mr. Gachelin, and Mr. May. Songs and recitations by the members formed an important feature of the evening's entertainment, and the proceedings were brought to a close by the company singing the French, Belgian, Swiss, and English national anthems.

A RESTING TOUR.

How the papers get filled during holiday time is one of the mysteries—that is if reports be true, for these tell us in their babbling way that scribes and comps *will* “rest” then, whatever the consequences may be. Facts prove the fallacy of such fancies, for the papers were filled as usual, and came out to the moment, rather proving that comps at least rank among the most industrious and self-denying of people. As for the scribes, they have little ways of their own for meeting emergencies, and they give their pens a rest or a frolic when they can.

Since this pen was given free scope to dance along lightsofely, the old year with all its joys and sorrows has gone, but it cannot entirely blot out the memories of the past. Well it is if these are pleasant—a mellowed after-glow of warm greetings and fair scenes, even though these may be steadily vanishing in the misty distance of bygone days. One of these memories was an hour spent with a grand old man who was once famous for Orchids.

Before leaving home for roaming and resting an intimation was given to a knight of the pen of a desire to call, if Fate favoured, on Dr. Paterson of the Bridge of Allan. “Dead long ago!” was the sharp response. “Are you sure?” “Certain.” “When?” “Oh, don’t bother me, I am busy; but years ago.” That is the way these said knights meet each other in parry and fence with their pointed weapons. “Certainly he was an old man fifteen years ago,” was another venturesome remark; “but I had not observed any record of his death.” This brought the young knight up in his stirrups, and in voice stern and snappy came the decisive word once more, “Dead, I tell you. Why can’t you let him alone?” This was closing the door with a bang. The matter ended, and the doctor was regarded as “no more.”

A room at Keir, arranging for a call at Stirling *en route* for Glasgow and Rothesay. “You take train at the Bridge,” commenced the instructor—“Bridge of Allan.” A chord was touched, and memory re-awakened. “Did you know Dr. Paterson?” Such a question, asked within two miles of “the Bridge,” would no doubt seem very absurd, and brought the response, “Know Dr. Paterson! why everybody knows him; he was the making of the place, good quaint old doctor.” “But is he not dead?” “What! the doctor dead! No; and if you go see him you will find him very much alive.” “But what age is he?” “Oh! nobody knows; he has been as he is for years—seen the whole long town spring up, with its “hydro,” hotels, churches. He always said it was the healthiest place in the kingdom, and he seems as if living to prove it, and doing all he can to keep others alive too. A famous man is the doctor.”

A delightful autumn evening. A pleasant walk found us searching for the cosy retreat. Yes, this is the place. There is the glass in the little garden, and here is the name, all the same as before, but the surroundings all different, and the most brilliant flower garden of the season in front of a huge hotel nearly opposite. To the inquiry for Dr. Paterson, as we reached his door, came the professional response from the dainty maid, “No, sir, not in just now. Any message, please? but he will not be long. Perhaps you will step in.” “Yes, thank you, into the garden.” It was not the garden of fifteen years ago, and the houses only contained relics of the past. In comes the doctor, not bowed down with years, but brisk and active; a quaint, rather tall and spare figure, in conventional black and ancient white neckerchief, with the wide-spread wings of the olden time; long white hair hanging over his shoulders in wild abandon—almost a living portrait of his friend in youth and during a long life, the late celebrated Professor Blackie of Edinburgh.

“Eh, man, but I am pleased to see ye, and ye’re wifie—ye picked a bonnie lassie I can see,” was the greeting of the grand old courtier. No gardening noo; son’s gone; always wanted; always busy; folk don’t often die *here*, and want a little attention.” “But I was told that you were dead, doctor.” “What *me* dead! aye they’ve had me dead many a time, and I should have been gone fifty or sixty years ago but for coming here, and here I am as well as ever. Health is a question of common sense, man; but come in and partake of frugal fare and a glass of port to warm ye.”

What a museum is this home of the venerable doctor’s! Years of collecting in the form of relics and curios of all imaginable and unimaginable kinds are treasured here, piled and buried under each other. Ancient swords, daggers, books, chairs, portraits, letters of historic interest, with mementoes of the Queen and a

bit of her bride cake. Neither numbered nor named are half or even one-tenth of the precious relics; but the doctor knows them all, also all about them and their associations. What will become of them?—the result of a long life of searching and storing by a lover of his country and his Queen. Surely another such room, or room so filled, cannot be found in Britain. An hour spent in it takes us back to the turbulent times of long, long ago, and is something to be remembered. But time steals on, and it is late before we know it. “Good-bye. Always call and see me when ye come to Scotland, and bring the bonnie wifie; ye’el always be welcome here. Good-bye.” And so we left our entertainer—quaint and picturesque, a type such as is rarely to be met with in these modern days.

The next day to Glasgow; but a break was made at Stirling to see the ancient castle, perched on the summit of a wondrous upheaval of rock out of a level plain. A little enclosed garden with lawn, trees, and flowers nestles near the summit, and from the battlements beyond we look down the precipitous rock into the almost dizzy depth below; then descend (by another route) for a drive round the base of the old fortress, finding the great escarpment on the western side, a forest of wild Roses, and along the Bannockburn Road, the farthest way to the station. This “farthest way round” was, in accordance with the old adage, for the purpose of “seeing the most,” and enjoying the pleasant suburbs of Stirling.

From Stirling to Glasgow is only about an hour’s run by express, and a pause of an hour or two was made for seeing the “second city in the Empire” and the Botanic Gardens. We saw a little of both, or perhaps it should be said a good deal of the one and very little of the other, for the Gardens were only seen from the outside. It was in this way. A station Jehu was asked to drive us through the city to the Botanic Gardens and back by 4.30. “Oh, aye! ye want to see the toon; it’s a grand toon, ye’el ken.” True, it is a fine city, with broad streets and noble buildings. The worthy man kept time to the minute, for he stopped at the Garden entrance, turned round, and rushed back to the station, arriving there exactly at the specified time. The intention was to have had half an hour or so in the Gardens, and a handshake with Mr. Dewar, but the pleasure was denied us by a precise and conscientious driver. He must have clearer instructions next time—not simply be told to drive to the Gardens, but be informed we wish to go *in* them for awhile, and he must drive through the “toon” accordingly, instead of all over it. It was a case of being “so near, and yet so far”—two or three minutes perhaps from Mr. Dewar, yet for the purpose of a friendly grip, as far as the hands are apart now, or over 400 miles. The incident points a moral—namely, if you want your wishes carried out express them so plainly that they cannot easily be misunderstood, and if you fail in that, and things go wrong, do not blame the coachman.

Off to charming Rothesay. There are three ways of reaching the Isle of Bute from Glasgow. 1, By steamer all the way, about

FIG. 11.
MR. CUTHBERTSON.
(See page 36.)

three hours. 2, By train to Greenock, about forty-five minutes, thence by steamer—an hour. 3, By train to Wemyss Bay, express about fifty minutes—steamer thirty minutes. Fares low, and return tickets available by either route. A convenient train (4.40) started for Wemyss Bay, only stopping once—at Paisley—and brought to mind a “Pansy man” there, bearing a great horticultural name—William Paul. Rothesay was reached before 6.30, or just in time on an early September evening to see the delightful surroundings of the crescent-shaped bay and the attractive town winding round as a terminus—the hills of Argyllshire on the right, with openings to the lochs, the Fir-clad slopes of Bute on the left, the pier and gardens well “peopled”—not with boisterous trippers, but with visitors of the best type, who love to see the splendid boats come and go, as shown in the photographic reproduction obligingly furnished by the “Buteman.” Not much of a garden scene. No, perhaps not; but would that numbers of gardeners could have a week of autumn rest at this fair and salubrious place, to which many garden lovers find their way, not to return disappointed.

We had, alas! but two days on or among the Western Isles—one on sea the other on land, and half the land day rainy, this preventing a visit to Mount Stewart, the princely seat of the

Marquis of Bute, four or five miles from Rothesay. This, as the "Buteman" Guide informs us, is "the acknowledged queen of Scottish watering places." It is the queen of all that we have seen, and served by the most queenly steamers, of which it is said that some forty call daily in the summer to and from the many lochs that intersect the land and wind away for miles between bold hills and glen-like dales that recede till they melt away in the distance. But there is much more than sea and pleasure craft skimming its surface at Rothesay. There are hilly drives through the greenest of fields; there are shady and picturesque woodland walks; there are flowers there of the best and in the greatest profusion.

occasionally, or of whom we have read—and have a restful talk, to racing up and down their "grounds" after being saturated with a season of shows.

We had two such pleasant evenings—one with Mr. Cuthbertson in his charming Swiss chalet-like home in the wood—"Firwood"—overlooking the bay; the other with Mr. John Dobbie—the "original Dobbie"—in his mansionette beyond the Firs, but almost close to the breezy sea. The first was an evening of music and flowers—music vocal and instrumental by Mr. Cuthbertson's talented friends; flower and show lore by Mr. Jones, his competent nursery manager, enlivened by the "pawky," humorous inter-

FIG. 12.—A VIEW OF ROTHESAY.

Though not on a garden-hunting tour, we could not but know, in common with all the world of horticulturists, that Rothesay is the headquarters of "Dobbie's;" also that Mr. Michael Cuthbertson, a noted florist, has a nursery there, from which he cuts the flowers that his competitors do not much like to see at many shows, any more than they do Mr. Alexander Lister's. It should be said, however, that Messrs. Dobbie & Co. are not competitors in their classes, so far as we have seen, and it was the desire of the head of this now great firm (Mr. William Cuthbertson) that after a glance at its fields of flowers we should go on and see "Michael"—whether as a relative as well as a friend of our guide is not known. It was only by a rush between the showers that we could carry out half the programme, and this in a half-hearted, fearsome sort of way, in view of a momentary drenching. We prefer to see the friends at home—friends we may have met

ludes of his happy partner, Mr. A. McIndoe Burnie, the third partner, Mr. Robert Fife, having charge of the branches in Kent and Hampshire, but coming in the morning. A delightful evening truly; but what shall we say of the next at Mr. Dobbie's?

From the firm that this fine old florist and horticulturist founded and established he has long since retired. The business grew and grew till it ate up his commodious house and all its appurtenances in High Street, and the time for rest had come. But the spirit of improving strains of flowers and vegetables, in searching for and fixing the best, that made him famous, is with him still, and the delight of this veteran in his garden at home is in Leeks and Beets, and whatever he grows, to beat if he can Dobbie's in the town. Mr. John Dobbie was not, as many think, a gardener in his early days, but an amateur. He did not seek to make a business, but his

strains and selections, now long ago, became so popular that a business was so to say forced upon him, and in time increased, till as above indicated, it turned him out of his home; but not unhappy, for a more happy, genial, interesting man, and more real lover of the garden and its crops, it would be hard to find. His hospitality was almost overwhelming, and his converse of the past most entertaining. It is said Mr. Dobbie is an octogenarian; if this is really so there can surely be few like him, for he is as straight, sturdy, and active as even healthy men are commonly seen before they reach the "sixties." However, whether there has been any mistake in age or not there is no mistake about Mr. Dobbie being a genuine man. It was a treat to spend an evening with him and his help-meet, who is the equal of himself in making his visitors linger till late in their bountiful haven of rest on the eastern shore of Rothesay Bay.

But are we to have nothing about the nurseries of Dobbie and Co., of Cuthbertson, Burnie, and Fife? Very little. The several catalogues are a faithful reflex of the whole. Of Pansies and Violas there are acres—a singularly complete collection. Of Dahlias still more acres—certainly one of the greatest emporiums in the world of the grand "autumn" flowers, of which a brilliant collection was shown at the early summer show of the Royal Horticultural Society in the London Temple Gardens last "May." Think of it, Dahlias in May! Novelties, surely; and as such graciously accepted by the Queen. The twirling Cactus forms figured freely, as they will in many a drawing-room in the future, and it may be expected that all kinds will figure attractively in the forthcoming monograph, edited by the head of the firm, whose "head" may be seen in fig. 11, page 34—a gentleman of decided literary capacity. Then as to all the rest of the border and florists' flowers; they are all in the grounds. There is no mistake about it; but in September cartloads of gay bunches were in the sheds waiting their turn to be sent to many shows. Under glass, Tomatoes commanded attention—a forest of plants of the Champion, roped with smooth, firm, scarlet fruits just of the right size for market; while for fragrance were the Tea Rose scented and rose-tinted tuberous Begonias, showing that Dobbies are up to date, and it will be their own fault if they lag behind. But we must leave them for a day on the lochs in the noble "Lord of the Isles."

The Clyde steamers are admittedly the finest pleasure boats in the kingdom. They are floating palaces and hotels—temperance and otherwise—conducted in the best possible manner. About three hours after leaving Glasgow they call at Rothesay, and proceed up the different lochs. For a long run, some sixty miles, we take the "Lord of the Isles" for Inveraray, pass through the Kyles of Bute (from the Celtic *caol* or *caolus*—a narrow passage) leave Tighnabruaich on the left, where lives the Pansy man, Mr. A. Irvine, and go on past Ardlamont Point, through Loch Fyne, till in the course of three or four hours we arrive at our destination close to the Castle of the Duke of Argyll, "land," remain on shore for an hour or so, then return. To and fro, a run of more than 100 miles, and at what price do you think, dear reader? You would not think the return ticket dear at 2s., would you? It was no special "cheap trip," but the ordinary fare. True, if you wish to be extravagant and aristocratic you can pay 4s. for the saloon end; but the "fore" is just as good, while many like it better, except, perhaps, at dinner time, where the menu of the *table d'hôte* is choicer and terms naturally somewhat higher.

Acting on the advice of two charming young lady amateur guides, who pointed out and explained features of interest on the way, we took tickets for the "fore," and all went well till dinner time, and not very badly then. As only the best could be offered for much kindness places were booked for the saloon dinner, which was excellent, and the price not extravagant; but during a little chat "abaft the funnel" the purser came to examine tickets. "Ah!" (sharp purser), "wrong end; another shilling, please." "But we have only been to dine." "Yes, sir, another shilling." "Then if we travel 5 yards to spend 5s. extra on the ship we have to pay for the privilege of crossing the line to do so." "If you like to put it so; but you are here, and it is my duty to take an extra shilling on the tickets." A matter of small consequence, but just a question of being "caught" and marking an anomaly; for be it noted we travelled nearly sixty miles for a shilling, and then paid an equal sum for walking across the boundary to pay more; or, to put it another way, at the rate of five miles a penny for the trip, "resting" in a chair if we liked, and nearly 2d. a yard for walking to dinner. Such little surprises are good for the memory. As to the pocket, well, when you go a touring you have to "pay," at least such is the experience of—
THE SCRIBE.

HARDY FLOWER NOTES.

"BRICKS without straw" might well be the heading of these notes now. Flowers there are in bloom it is true; but these are few and have been spoken of before, and the garden is in its dullest time. Recently it was as frosted silver. Tree and bush; withered stem or mound of verdure; level ground or rockwork pile were glittering with tiny crystals. With that silver plating which the most skilled worker in metals could not hope to rival, the network of the hedges was beautiful to see. Thorn, and bud, and branching bough were covered with their silvery coating, and even the haws which still keep crimson at Christmas Eve were frosted over. The veil of mist which hung o'er all was drawn aside, and the cold sunlight of December shone for a time upon this wintry scene, and gave it a greater glory—cold though that glory seemed. Hard was the soil, and the adventurous Snowdrops and Crocuses were arrested in their eager desire to win our admiration.

The Water Lily pool was covered with thick ice, through which we could only faintly discern the crowns, which, when summer comes with genial breath, will yield us their fairy flowers afloat upon the waters, which—though now congealed and chilling even to see—will then give a welcome coolness. Everything was wintry, yet inexpressibly beautiful. That blackbird, with ebony garments and yellow bill, which comes to the window side to breakfast off the berries of the Cotoneaster, looking quickly round to see if danger were near, seemed like Keats' owl, which "for all his feathers was a-cold." He is black but beautiful indeed, and for his beauty is welcome to the berries in return for his company. In summer we are less pleased with his presence (though his music is welcome), by reason of his raids upon the Gooseberries, the Strawberry, and Peas. Then we are apt to greet him with explosions of wrath, forgetting that even then he does some service in return, and only claims his just recompense. The tits and the robins are about also, while the perky sparrow is never absent, seeking crumbs by day, and by night resting on the Roses on the house front.

But as the misty veil was drawn back the clouds aloft were seen driving from the west, and through the night the frost vanished and the silvering fled before the south-west wind and heavy rains. The ice is melting swiftly, and though the skaters and curlers may grieve the Snowdrop and Winter Aconite will rejoice. The latter will be in flower in some gardens, but here it is just coming through the soil with its little yellow flowers protected by their green ruff. "Too common," perhaps, for some folk's gardens, but of welcome brightness in the dark and gloomy days of winter, and doubly welcome for lighting up a dull corner where something lively is needed at any time, but especially at present. One such corner here has, by way of experiment, been planted with Lily of the Valley and Winter Aconites intermingled. Should these succeed, as they are expected to do, a pleasing picture will be formed both when the Aconites dare the storms of January and when the Lilies of the Valley

"Droop on slender threads
With broad hood leaves above their heads,
Like white-robed maids in summer hours,
Beneath umbrellas, shunning showers."

But these are pleasures of anticipation; sights of the days we may never see; and we must turn to the winter-flowering Jasmine on the wall, to these white Christmas Stocks, to the Primroses, the few Crocuses and Snowdrops, or to the greenery around for subjects of thought.

That Jasmine with its golden stars is a winter flower that some despise, but which we cannot well spare, with its green branches and its yellow blooms. On the wall it gives that touch of gold we love to see, and small though its flowers are, they are flowers still, and with beauty of their own. At the foot of the south-west gable of an outhouse in a narrow border are some white Christmas Stocks, the seed of which was procured nearly two years ago to produce plants to flower the following Christmas. This they did, and last spring were turned out into the border, where they have been almost continuously in bloom. They have stood the frost well, and this day of Christmas Eve quite respectable flowers could be cut, though a water cask near had ice nearly 5 inches thick on its surface. These Stocks were recommended for greenhouse work at the festive season, but it is pleasant to have them outdoors too, though their beauty may be a little dimmed by frost and rain.

On the wall behind is a plant of the rare *Lathyrus pubescens* from Uruguay, kindly given to the writer by a connoisseur in flowers. What disaster this or other winters may bring to it time alone will tell, but much to our surprise this South American Perennial Pea remains as yet fresh and green, and unharmed by the ordeal it has undergone. It did not flower last summer, but it was only a young plant then, and not strong enough for blooming. May winter spare it so that 1897 may afford us the treat of

a sight of its flowers. The leaves are distinctly pubescent, and the plant, taking it all in all, quite attractive.

The Primroses seem even more wan and melancholy than when last we wrote of them. Carew tells us why this

"Flower does show
So yellow, green, and sickly too."

The younger portion of my readers may be interested in his reply:

"I must tell you these discover
What doubts and fears are in a lover."

As days lengthen, however, they will look brighter by far, and in sheltered nooks in the garden as in the woods will show their modest beauty at its best.

The Crocuses are wearying for more sun, and *C. hyemalis* Foxi, with an early bloom or two of *C. Imperati*, keep their "cuplets" fast closed. When the sun returns with a little stronger power Fox's Winter-flowering Crocus will display its white cups with their black anthers, which contrast so well with the colouring of the segments of the flower; but although a few of *Imperati*'s Crocuses may bloom at the same time it will be later ere the majority delight us with their beautifully coloured flowers. Many of the Snowdrops are white-tipped or are drooping already to show us their loveliness. They are not as a rule unusually early, and have made little progress for some time. Of these we must speak again.

The remark of the Rev. D. R. Williamson, in his pleasing article in the Journal of the 24th December, regarding *Chionodoxa Luciliae* being in flower, is an interesting one, which leads to the inquiry if the bulbs are established or newly imported ones. Although Kirkmaiden is an early district, the Glory of the Snow is so much before its usual period that one is inclined to think that the roots have not been established, and have thus not been accustomed to our climate and its ways. Perhaps your accomplished correspondent can tell us.

Ere long, however, the Glory of the Snow shall come here to tarry for awhile with the Snowdrops, the Scillas, the Netted Irises, the earliest Saxifragas, and the other gentle flowers which hail the opening year. They come smilingly, though Nature seems to look upon them with lowering brow. Not so; they could not stand her smiling summer moods, and so they come to wish us, as we wish all readers, that "Happy New Year" we all desire. May the blooming of these early flowers bring true happiness and precious delight to all unmarred by aught of sadness or misfortune.—S. ARNOTT.

TREES AND SHRUBS FOR CHALKY SOILS.

I NOTED a correspondent, "G. K.," on page 10 of your last issue, asking for a list of shrubs that grow and do well on chalk. A near neighbour who laid out a large place and planted it with all, or nearly all, the best shrubs, was some years after asked for a list of those that succeeded; enclosed is a list of them. "G. K." may fully rely that these will be likely to give him satisfaction.

CEANOTHUS AMERICANUS.—A correspondent of "Meehan's Monthly" speaks in praise of *Ceanothus americanus*, or New Jersey Tea, as one of the plants which make an excellent low hedge, never grow beyond bounds, and look well at all seasons. It will endure dry weather well. It puts forth leaves and stems in early spring, and is soon covered with its feathery blossoms, and when the leaves have fallen the erect red stems are still handsome. In the north the winter sometimes kills back the young growth, but, in any event, the plant only needs one trimming in the spring.

THE ROSARIAN'S YEAR BOOK, 1897.

WE welcome the R. Y. B. for 1897 in the words of its this year's motto, "Perennial Rose" Book. "May its shadow," or rather its substance, "never be less." Its veteran editor has once more catered excellently for us—a well "varied menu," as he says, certainly not "a réchauffé." It contains two articles by the editor—the one a notice (with life-like photograph) of Mr. C. J. Grahame, the small grower's friend, who ran third, and that a good third, in perhaps the hardest fight of the year—the contest for the Sutton cup at Reading; the other, the N.R.S. history for 1896, a paper of great interest, and showing none of his natural force abated. Then we have poetry by the Rev. D. Williamson, and forcible prose by the Rev. A. Foster-Melliar, who gives a valuable analysis of the newest and best Teas, with a good word for some old ones.

"Madame Hoste in her war paint, prepared and sent out for conquest at some grand function by such efficient and clever ladies' maids as Messrs. Orpen or Jordan, is a beautiful Rose indeed, and a strong candidate for the medal if Elise in her old-fashioned radiance is not to be found. It should be remembered that papering, though it deepens the yellow, generally spoils the red shade."

Mr. A. Piper discourses on H.P.'s and H.T.'s of recent years. Those who wish to keep their Rose lore up to date will do well to study this paper with close attention. We can give but one extract:—

"The redeeming feature of 1892 was the splendid examples of what is perhaps one of our very best H.T.'s, originally shown and 'gold medalled' under the name of Mrs. W. J. Grant, and afterwards renamed Belle Siebriecht. This cross between La France and Lady M. Fitzwilliam was not given to the public until 1895."

Our largest amateur grower as I suppose, or thereabouts, Mr. Pemberton, discourses condescendingly on "less than 500." His advice is most valuable, though perhaps startling to small people, suggesting when starting, the purchase of twenty-fives and twenties, with even fifty of Her Majesty and Mrs. J. Laing—"not the 500," or anything like it—varieties. Every word he writes is noteworthy, and not least this suggestion:—

"I am sure of this, that a box of six that contained three fair examples of such grand Roses as Mrs. J. Laing, A. K. Williams, and Horace Vernet, no matter what the other three Roses were, provided they scored a point, would indeed be hard to beat."

The subject of the Hybrid Tea is returned to by Mr. George Paul, indeed his "foot is on his native heath" here, as his Cheshunt Hybrid began the series, and was forcibly driven into a class of her own. The H.T. is unquestionably the coming Rose, and every fresh acquisition shows yet more this Rose's excellence and possibilities. A very valuable paper is thus summed up.

"What have we gained in the new class of H.T.'s? 1, A nearer approach to hardiness in the light and yellowish coloured Roses. 2, The development in these hardier Roses of the more artistically beautiful flowers, which T.'s, compared with H.P.'s, have. 3, A new race or class, with free autumnal qualities so essential nowadays in an English garden."

Last, but not least, are two articles by the other Honorary Secretary of the N.R.S. He is nothing if not statistical, and his first article on "Medal Roses" is this in high perfection—"Almost any good exhibition Rose would appear to have a chance when in the most perfect phase of its possible beauty of securing a medal at some time or other," but Mr. Mawley's tables clearly show that only certain choice kinds have this distinction frequently conferred upon them. The result of eight years is given:—A. K. Williams won the medal 20 times; La France, 18; Mrs. J. Laing, 17; Her Majesty, 14; &c., &c.; Comtesse de Nadailac, 26; Souvenir d'E. Vardon, 19; The Bride, 15; Maréchal Niel, 8; &c., &c.

The usual "Weather Article" concludes the series. A bumper year has yet to be recorded. Last year broke the record as one of the earliest. It was the making in one way of the Reading Show. "At this exhibition 3975 blooms were staged, making this the largest show ever held by the Society in the south of England." It was held in the famous Abbey grounds, and several excellent photographs of the show and of the judges may be obtained of Mr. Victor White, Reading. N.B.—This is not an advertisement.

Mr. Mawley concludes, "It will be gathered from the foregoing history that our rosarians just missed enjoying an unusually grand Rose season, and that through no deadly winter or cruel spring frosts, but entirely owing to the prolonged drought and heat. . . . All went well until about the middle of May. . . . From this time adverse weather conditions prevailed, consequently the first flowering was soon over, and the blooms, when they came, although mostly well formed, were unusually small and thin."

We conclude with a stanza of Mr. Williamson's sweet "Memories."

"Stars of the earth, that fill the earnest mind
With thoughts of that deep rest which dwells above;
In you, O peaceful flowers, our spirits find
The likeness of His life Whose name is Love."

THE YOUNG GARDENERS' DOMAIN.

FROM THE FOUNTAIN PEN.

I WISH to convey my thanks to "E. K." for his kindness and thoughtfulness in offering the beautiful fountain pen, which I feel proud to have won and received. A fellow gardener once said, when talking of a class he was attending, that he could not rouse his enthusiasm in the lectures, as there was no enticement in the shape of prizes. The "Domain" writers cannot tender this excuse, for we have now some allurements. I received a writing book this Christmas, and now I have a fountain pen. May I possess along with these the needed tact, accuracy, and wisdom to become a good writer. If, "E. K.," I cannot write you a flowing effusion of thanks, know that I feel my gratitude. My thanks also tendered to the Editor.—J. H. DICK.

VINE PRUNING.

IT is not without some trepidation and misgiving that I enter upon the subject I have chosen for this article, as I am aware that it refers to very important work in garden routine, and I think one which, as a rule, young gardeners are not credited with knowing much about. However, as our kind Editor has given us permission to try, and encouraged us in so doing, I will without further preface endeavour to state my views on Vine pruning.

In the first place let me say that a sharp "Saynor" is a *sine qua non* (I hope the Editor will pardon the Latin), because a clean cut heals much quicker than a rough jagged one, and has a tidier and more workmanlike appearance.

No hard and fast rule can be laid down for pruning a Vine, as the individual condition and requirements of each one must be considered. For instance, early forced Vines require rather different treatment from late Vines, which start naturally in the spring. The former do not make such good growth as the latter; the consequence is that plump well-formed buds are not so plentiful.

The best bud nearest to the base of the shoot must be selected, and the shoot pruned back to it. If the best buds are cut away for the sake of having a short neat-looking spur, good fruit-bearing growths cannot be expected. If one spur die the one below should be left rather longer in order to take its place. The same remark applies in the case of a weakly spur, which may be cut out the following year.

When there is room between the Vines it is a good plan to train a shoot from the base, eventually to take the place of the old worn-out rod. This method of pruning is known as the long spur system. Its object is to continually encourage young wood in place of the old. By these means the life of the Vine is prolonged, and its fruit-bearing capacity is increased. Some varieties, as Barbarossa, Duke of Buccleuch, Golden Hamburgh, and others are of a delicate nature, and succeed well on the above system of pruning. The spurs may very often die back, so that young growth is necessary to the life of the Vine.

It is not difficult to find good buds to prune to on Vines allowed to start naturally, as these produce much better wood than early forced ones. If when the Grapes are cut the shoots were partially shortened it would be found to plump up the back buds considerably. In some establishments, more especially in market nurseries, the Grapes are left hanging on the Vines, for want of a suitable fruit room in which to store them. If the Vines have started into growth before the fruit is removed, as sometimes happens, they are then simply disbudded. Afterwards, when the Grapes are cut, the disbudded portion is pruned closely back.—H. H.

[One of the neatest, most carefully and accurately written first articles we have yet received, while what may be termed a great subject is well compressed in the limited space. Can "H. H." next describe the treatment of Vines from starting to flowering (not beyond), describing temperatures and processes, giving reasons for the different items in routine? He may if he wish occupy a little more space, and take all necessary time, as in the present instance, of doing his literary exercise well. Our young friends, as well as old ones, should know that the true "Barbarossa" Grape is pale red or grizzly, and that so far as we know all the Vines grown under that name in this country are Gros Guillaume.]

EUPHARIS AMAZONICA.

AMONG the many useful white flowers so eagerly sought after by ladies I think there are few to excel the beautiful Amazon Lily, and considering the plants produce abundance of bloom (if properly cultivated) in the depth of winter they are the more valuable. Whether the flowers are used as buttonholes or in bouquets or wreaths they look exceptionally handsome. Another good quality they possess is, they last a long time in a fresh state after being cut. When grown to embellish the stove or other warm house their lovely white, wax-like blooms, combined with beautiful dark green foliage, make them unsurpassable.

The Eucharis, as far as I have seen, is not one of the most easy of culture, as the plants require a great amount of careful attention, especially as regards watering. I once served under a very successful grower of Eucharises, but eventually the plants seemed to lack their usual vigour, and some died. The first signs were the leaves turning yellow and sickly, and the leafstalks presenting several rust-coloured spots. On examining these with a pocket lens several tiny insects were found; the bulbs, too, were found to be affected, and on some of them being cut in two we found that this pest had eaten the flowers right away. What was to be done to get rid of this pest? The

bulbs were immersed in a mixture of urine and soot for four hours, some being left a whole day, when they were taken out and repotted in a compost of three parts good fibrous loam, one part well decayed leaf mould, and a sprinkling of coarse sand, all well baked to kill any insects or eggs that might be therein. The pots were effectively drained, four to six bulbs (according to size) being placed in 16-size pots, and the soil made firm. They were then placed in their old quarters, where there was about 70° bottom heat and 65° general. They then started, and continued growing vigorously as if nothing had happened. Perhaps some of my young brother gardeners have seen similar occurrences.—ASPIRANT.

[Useful, but the writing much too close for proper revision.]

EARLY FORCING—PEACHES AND NECTARINES.

ON account of the close relationship of the two fruits named, the Nectarine being but a smooth-skinned Peach, the same mode of treatment is applicable to both.

The houses should always undergo a thorough cleansing before the trees are started into growth, the trees then removed from the trellis, pruned, and retrained. It is also advisable to syringe them well with some good insecticide to make sure of destroying all insects.

We next direct our attention to the borders, point them over lightly on the surface with a fork; we next sprinkle them with lime and a quantity of wood ashes, then a top-dressing of good fibrous loam, about 2 inches in thickness, and if the trees are in a weak state of growth add a quantity of bonemeal, and make the borders as firm as possible by trampling them over.

After the borders have been well watered, the trees may be started into growth in a temperature of about 40° to 45°. The syringe must not be used too freely until after the flowering period, so as not to encourage growth in advance of the flowers. If the fruit buds are overcrowded, it is best to thin out all weak ones before they are opened, so as to leave room for the stronger to open freely.

The atmosphere should be rather drier than usual during the flowering season, and in dull weather a little extra fire heat should be given, with a free circulation of air through the houses. To insure a good set of fruit, it is best to assist the distribution of the pollen by drawing the tip of a rabbit's tail over the flowers lightly when they are fully expanded and the pollen ripe. This process must be repeated each day when the atmosphere inside is as dry as possible, then tap each branch lightly with the hand. The paths and borders inside may then be damped with a can, and do not syringe the trees until the petals begin to drop, showing that fructification has taken place, when a gentle dewing of the trees with tepid water from the syringe will do much good by assisting the embryo fruit to swell freely, when the temperature may be raised gradually to 55° or 60° by night and a little higher during the daytime.

Disbudding may next be proceeded with. This operation is best done at intervals of about a week or ten days, as then there will be but little danger of checking the growth when a little is removed each time. In the first place rub off with the finger or thumb all "breast shoots," leaving only the well-placed side shoots. The next time we leave two sprays at the base of each piece of bearing wood laid in, and another at the extremity, but if these are more than the average distance an intermediate one may be left. At the final disbudding only one spray is left at the base of each shoot, and it should if possible be on the upper side, as, being the best situated, the training may be carried out properly, and to prevent unsightly bends at the lower ends of the young shoots, give them a tie, at an early stage, to the one branch from which they emanate.—J. F. DONOGHUE.

(To be continued.)

R.H.S. EXAMINATION.—HORTICULTURAL PRACTICE.

(Continued from page 17.)

Question 1.—"Describe the preparation of the ground for the Onion crop; the method of sowing the seed, and subsequent treatment; also the most suitable soil."

The ground on which Onions are to be grown should be trenched in the autumn, leaving the surface as rough as possible. Unless the subsoil be of a suitable nature, it should not be brought to the surface or mixed with the surface soil, but should be broken up with a fork in the bottom of the trench, at the same time mixing one barrow of farmyard manure and a bucket of quicklime with every eight square yards of ground. If the subsoil be good it may be mixed with the surface soil, together with one barrow of farmyard manure, and 7 lbs. of wood ashes to every six square yards of ground. If wood ashes are not obtainable use 2 lbs. of kainit, and 2 lbs. of basic slag phosphate instead. Early in March rake the surface of the bed level, and tread the land very firmly, choosing a dry day for this purpose. After treading rake the surface level, and sow the seed in shallow drills 1 foot apart, leaving out every fifth row to form a path. The seed should be sown thinly, so that when the seedlings grow they would stand about three-quarters of an inch apart. Cover the seed with soil, and make the surface of the bed level and firm.

The subsequent treatment consists of keeping the bed free from weeds, hoeing the soil to prevent it cracking, and also to retard the evaporation of water, thinning out the Onions until they stand about 6 inches apart, and feeding the plants every fortnight during May and June with $\frac{1}{2}$ lb. of nitrate of soda per rod. Time, twenty-five minutes.

Question 2.—"What are the circumstances which should regulate the frequency of watering, and the amount of water to be given to plants in pots?"

The circumstances regulating the frequency of watering will depend to a considerable extent upon the following circumstances:—1, The weather; 2, The season of the year; 3, The soil; and 4, The kind of plants to which water is to be given. If the weather be windy, sunny, or hot plants will require more water than if it (the weather) be still, cloudy, or cold. Plants also require more water during the spring and summer months than they do during the autumn and winter. Soils that are loose, gravelly, or sandy require watering more frequently than peaty or clayey soils. Some plants grow more vigorously than others, and as a general rule the former require a greater supply of water.

The amount of water to be given to plants in pots varies according to the extent of foliage and roots they (the plants) possess. Plants with few roots and narrow or leathery leaves, do not require so much water as those which have many roots and broad soft foliage. Plants which have been recently repotted do not require so much water as those which are established. Time, sixteen minutes.

Question 3.—"Describe the most suitable soil, and method of culture, for such tap-rooted vegetables as the Carrot and Parsnip."

(a) The most suitable soil for crops like Carrots and Parsnips would be a deep rich loam, as free from stones as possible. (b) The land for these crops should be trenched, and a liberal supply of decayed manure added during the autumn. When trenching break the soil up as small as possible, or the roots will become forked. In March dig the soil over with a fork, making the surface as level as possible. The Carrot seed should be sown towards the latter end of March, in drills 9 inches to 1 foot apart. Hoe the surface frequently, and thin out the plants until they stand 9 inches apart in the row. The soil for the Parsnip seed should be prepared in February, and the seed sown then, on land prepared in the same way as for Carrots. Sow in shallow drills from 1 foot to 15 inches apart, and thin out the plants until they stand 1 foot apart in the row. Time, twelve minutes.

Question 5.—"Give the names of the best varieties of Strawberries. What is the most suitable soil for their culture? Describe the culture in detail for forcing and open ground."

(a) President, Newton's Seedling, Royal Sovereign, Sir Joseph Paxton, and La Grosse Sucrée. (b) Deep rich loam, overlying gravel or chalk, forms the most suitable soil for Strawberry growing.

(c) Forcing plants are obtained by pegging runners into 3-inch pots filled with rich soil, and as soon as rooted shifted into their fruiting pots (32's). The larger pots must have good drainage, and the soil cannot well be rammed too hard. The soil should consist of a mixture of three parts fibrous loam, one part decayed manure, and one-sixth part of bone-meal. The runners should be layered as early as possible.

When the plants are potted stand them on ashes, give water when needed, and place them in a cold frame as soon as severe frost occur, removing the lights on every favourable occasion. The plants should be removed into the houses for forcing as required. They will require watering carefully, and syringing until the flower buds begin to expand. As soon as the fruit is set weak liquid manure should be given frequently, and when the fruit begins to ripen a drier atmosphere and more air is needed.

The culture for out of doors consists in selecting runners as early in August as possible, and planting them in prepared ground 18 inches from plant to plant, and 3 feet from row to row. When planting spread the roots out in a natural way, and do not get the crown of the plant below the surface of the ground. Remove runners as fast as they appear, and hoe the land to keep it free from weeds. Long manure or straw should be placed in the rows about the time the plant begins to flower, to keep the fruit clean. If the weather be dry give water and weak liquid manure if possible. Time, twenty-five minutes.

Nine questions, running from 1 to 9, were set last year on "Elementary Principles," and nine questions, running from 1 to 9, on "Horticultural Practice." Unfortunately I omitted to write "Elementary Principles" at the heading last week.

Before I finished I intended giving young gardeners a few words of advice on the exam, but my answers will already take up a considerable space in the "Domain." With the Editor's permission a little friendly lecture will be given another week by—A STUDENT.

[Permission is readily given for advice that may be useful to other young gardeners.]

VACCINIUM ERYTHRINUM.

ALMOST any plants that flower at this time of year are welcome in the greenhouse, and that of which a small bunch is shown in the engraving (fig. 13), though not remarkable for its richness of colour, is well worthy of a place in collections. It is of strong habit, producing its flowers freely in December and January, and can be readily grown under the ordinary treatment afforded to greenhouse plants. The flowers are of a peculiar dark purplish red colour, and are borne in racemes at the extremities of the bunches. It has long been an occupant of British gardens, but appears to be very little known.

COUNTY COUNCIL TEACHING.

If your readers are to believe all they see stated upon the above subject they must think that either some teachers are incompetent men, or your correspondents are not endowed with a superfluity of caution. I happen to know that the first sentence of the paragraph on page 422 of your last volume is untrue. The writer of it sent the statement to you without knowing a single fact of the case. The last sentence of the paragraph I know nothing of, and Mr. Hughes repudiates all knowledge of it.

Your correspondent "South Wales," in your last issue (page 10) naturally infers that the paragraph he saw was a fair version of facts, and he proceeds to give another instance of what he considers wrong teaching. His statement may be correct; on the other hand, it may be as unfounded as the sentence to which I have referred. When a person is so certain that a public teacher is giving faulty instruction at the expense of the public, surely he feels sufficient confidence in the righteousness of his cause to enable him to sign his name to his protest, and not require the use of a *nom de plume*!

It is foolish to suppose that men who for years have held prominent

FIG. 13.—VACCINIUM ERYTHRINUM.

positions in the front rank of practitioners, should degenerate into mediocrity the moment they devote a large portion of their time to imparting their knowledge to others. The very nature of their new and varied work produces the reverse effect. They are compelled to study harder and think deeper, and take broader—though not less sound—views than ever before, if they are to fit themselves, and keep themselves fit, for their work.

Men who have to stand cross-examination—by all sorts and conditions of men—upon the subjects treated, and to stand that successfully night after night and year after year, are not horticultural weaklings. Possibly there may be here and there men who are not best fitted for the work in view, and these may have been engaged on the principle of—"if we cannot have whom we would like, we must have whom we can get." But such teachers are mainly temporary. The majority of "so-called Technical Instructors" are quite up to their work as such, and doubtless can hold their own in practice with the best cultivators in the country, but they do not lay any claim to infallibility.—J. UDALE.

[The paragraph to which our correspondent first refers appeared on October 29th, 1896; his correction reached us on January 9th, 1897, so it does not appear in his view to have been very urgent. The advice referred to in the same paragraph, and which Mr. Udale "knows nothing about," was inserted on the direct authority of a gentleman who followed the advice that was given to grow Tomatoes in trenches prepared as for Celery, with the result of having gross stems and leafage, but no fruit. We fully agree that the majority of horticultural instructors are sound, practical men, and if we had not regarded Mr. Udale as being in the "front rank" we should not have testified to that effect long ago, as we did with pleasure; but he knows very well that all are not equally endowed with knowledge and the gift of teaching.]

HARDY FRUIT GARDEN.

Pruning Outdoor Vines.—When Vines are crowded with surplus rods or spurs these should be well thinned out. Strong young canes extending from any parts of the Vines, and which have had the chance of becoming fairly well ripened, may be retained for filling vacant spaces. Shorten them to not more than 4 feet. Similar growths may be encouraged during the next growing season, selecting them from near the base. These may eventually take the place of any further exhausted parts.

Vines confined to the spur system only may have the lateral shoots shortened to two buds, training in the best and most fruitful of the growths which start in spring. Some Vines are only allowed a limited number of rods furnished with spurs, the rest of the space being occupied with younger wood.

The long rod or extension system may also be exclusively employed, in which case there will be no spurs older than a year or two. The periodical renewal of growths, avoiding overcrowding, is the best system as a rule for outdoor Vines.

Cleansing.—In very hot situations in summer the foliage is frequently attacked by red spider or thrips. In order to destroy the pests the rods must be washed over with soapy water followed by a dressing of some effective insecticide. One of the best is Gishurst compound. Dissolve 4 to 8 ozs. in a gallon of water, and use warm. It will act effectually if applied as a lathery solution, or it may be thickened to the consistency of thin paint by adding clay, loam, or soot. In either case apply the dressing with a painter's brush, reaching every available angle and crevice. Another serviceable wash consists of 4 ozs. soft-soap dissolved in one gallon of water, adding a handful of sulphur, also a little clay to thicken the mixture. This is also applied with a brush.

Thinning Old Orchard Trees.—Good results invariably follow an intelligent reduction of the crowded branches of standard orchard trees. In the first place, however, the trees should stand at least clear of each other. It is not quite satisfactory to thin the branches only when the trees have been originally planted closer together than they ought. Remove branches and spray from the centres of every tree. Dispense with interlacing branches, more especially on the outsides. This will encourage the trees to assume form and shape, as well as productiveness.

Pruning Gooseberries and Currants.—Continue pruning bush fruit as opportunity offers. Thin out Gooseberry bushes well, leaving a liberal amount of young wood disposed regularly and thinly. Remove altogether shoots or branches which touch the ground. Naturally drooping varieties should have the lower branches pruned to buds pointing upwards. In selecting shoots to retain choose those growing upwards rather than downwards. Weak wood cut out entirely. The best for fruiting is of moderate strength, well ripened, and not too long. Dust freely with dry lime on a damp day, as a protection against ball-fishes, starlings, and sparrows.

The side shoots of Red and White Currants require cutting back to an inch of their base, where the fruiting spurs are arranged in clusters close to the main branch. In pruning bushes not fully grown the terminal shoots may be left 6 or 8 inches long. Vacant spaces in bushes may be filled whenever necessary by encouraging a strong young annual shoot to extend, shortening it at the winter pruning to 8 or 9 inches, so that the following season side shoots will be developed freely. These, reduced in length in summer and shortened to an inch in winter, will form fruiting spurs at the base.

Black Currants may simply have the oldest portions of wood removed annually and the best of the youngest encouraged, chiefly selecting that nearest the base of the bushes. The trees bear freely on young wood. Dispose it 4 inches apart, preferring that growing erect, and not crossing.

Heading Apples and Pears for Grafting.—Any old trees healthy in character but inferior fruit producers may be grafted in spring with well proved varieties. As the sap is not now active, this is the best time to head down the large branches near to the position where the grafts are to be inserted.

Scions for Grafting.—In the course of pruning the most suitable shoots for affording scions should be selected, tied in small bundles, named, and laid in in moist soil. It is important that a cool, sheltered situation be chosen. The buds must remain dormant. The scions prepared from these shoots will then be in a proper condition for inserting as grafts when the sap rises in the stocks.

Lime-washing Fruit Trees.—Though the application of lime-wash may be considered rather disfiguring to trees in conspicuous positions, it has the effect of cleansing the bark of minute vegetable growths which frequently accumulate on the stems and larger branches of fruit trees. Old specimens in orchards and exposed positions in gardens are chiefly affected. Sulphur added is beneficial, and the wash may be toned down with soot if the white colour is objected to. The propor-

tions of the above substances to form a useful cleanser may be four parts hot lime, three parts sulphur, and two parts soot. Mix to a proper consistency for applying easily with a brush when the bark is damp or wet.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest House.*—The recent dull, wet weather, combined with the mildness, has not been favourable to the setting of the fruit, as the tendency is more in favour of wood growth than blossom development. The chief thing to aim at is the fertilisation of the flowers, which, having developed in a comparatively genial and well-ventilated atmosphere, will have opened well and be duly furnished with pollen. Raise the temperature to 50°, if it have been lower through the night, as soon as possible after daybreak, and maintain it at that figure during the day by artificial means, putting on a little air so as to induce a circulation without causing a draught. Maintain a genial atmosphere by damping the paths and borders in the morning and early in the afternoon of fine days, but in dull, wet weather an occasional damping will suffice.

By ventilating early with a suitable temperature the trees are kept in steady progress, the blossom become perfectly developed, and fertilisation then is readily effected. The pollen may be distributed by means of a camel's hair brush, feather, rabbit's tail mounted on a small stick, plume of Pampas Grass, or shaking the trellis. The night temperature must now be 50° to 55° in mild weather, 55° by day from fire heat, advancing to 65° from sun heat. Increase the ventilation freely above 55°, but not so as to lower the temperature, and close at 65°, a few degrees advance from sun heat being beneficial. Remember that a well-aërated atmosphere is essential for the vitality of the pollen, and cross-fertilisation more potent than self-impregnation in many cases; besides, when pollen is deficient in any variety some should be supplied from another affording the golden dust plentifully.

Disbudding must not be done hurriedly, but any strong shoots of the previous year having a tendency to push growth in advance of the others may be commenced with, first removing the growths on the under side of the shoots, and then removing the side growths to the number required—namely, one from or near the base as possible to supplant that now fruiting, and another, or more, above or on a level with the fruit, and which should be pinched at a few inches of growth, or if the shoot be an extension leave growths at about every 15 or 18 inches to form the bearing shoots of next season, continuing those with the leader intact. Disbudding, however, should be commenced before the shoots are an inch long, and be continued at short intervals until no more shoots are left than will be necessary for furnishing the wood of the ensuing season's bearing. Afford due, but not excessive, supplies of water to the inside borders, and protect the roots outside with dry material. After the fruits are set an occasional syringing will assist the trees to cast off the remains of the blossoms, yet avoid heavy syringings, which have a tendency to weaken the growths.

Second Early House.—The trees to afford ripe fruit early in June must now be started, this house corresponding to the first in many establishments, which with the very early varieties give ripe fruit about the middle of May, the house having been closed at the new year. Employ fire heat only to maintain a day temperature of 50°, raising it early to insure the development of the blossom with light and due airing, increasing the ventilation at 55°, avoiding cold currents, and allowing an advance of 5° to 10° from sun heat and corresponding ventilation. A night temperature of 40° to 45° is sufficient until the blossom is well advanced for expansion, when it should be gradually raised to 50°. Syringe the trees in the morning and early afternoon on fine days until they show the anthers, when damping the borders and paths will be sufficient, admitting a little air constantly, with a genial warmth in the pipes. When the pollen becomes ripe artificial fertilisation may be resorted to. If water is wanted give a thorough supply, affording liquid manure to weakly trees, but warmed to the temperature of the house. Where the blossom buds are superabundant remove those on the under side or at the back of the trellis by drawing the hand reverse way of the growths.

Succession Houses.—These should be kept as cool as possible by free ventilation. The house to be started early in February, and the trees not previously having been forced, should now be closed, but if regularly started at that time they will not require any inducement to start at the proper time. The borders must be brought into a properly moist condition, merely excluding frost, and ventilating fully above 50°. Push forward the pruning and dressing of the trees in late succession houses, thoroughly cleansing them, securing the trees to the trellis, ventilating and keeping them as cool as possible. If necessary supply water at the roots, or liquid manure to weakly trees.

Vines.—*Earliest Houses.*—The weather having been mild and wet great care is necessary in ventilating on a recurrence of sharp and cold weather, for draughts injure the foliage, crippling the growths, and causing them to become stunted; but some air is necessary to prevent the leaves becoming thin and poor in texture, as they do in a confined atmosphere, and in that condition are liable to be scorched, and fall a prey to red spider. Disbud when the best shows for fruit can be distinguished; tie down the shoots before they touch the glass, taking care not to bring them down too sharply, or to tie too tightly. Stop two or three joints beyond the bunch, not, however, acting upon any rule of thumb principle, but be guided by the space at command, extending the stopping where there is room, and restricting it to one joint where limited, securing as far as possible an ample and full supply of foliage

fully exposed to light. Do not burden the Vines with superfluous bunches, one on a shoot is sufficient, for overcropping and overcrowding are great evils. As the bunches come into flower maintain a day and night temperature of 70° to 75°, falling 5°, however, during the night, and keep the atmosphere rather drier. Where fermenting materials are used on inside borders the heat must not be allowed to decline, but let the heap be turned and replenished as necessary. Outside borders must have attention, which will be slight, provided they have been covered with leaves and dry fern or litter; but where fermenting materials are employed they must be renewed, keeping up a good heap of Oak leaves and stable litter in the reserve ground to admit of a supply being obtained readily as required.

Houses to Ripen the Fruit in June.—Start the Vines at once. Supply the inside border thoroughly with water slightly in advance of the mean temperature of the house. To economise fuel employ fermenting materials within the house, throwing them into a ridge on the floor, and turn them frequently to liberate the ammonia and maintain a genial warmth and moisture constantly, adding fresh material as necessary. Where fermenting materials are not available, the surfaces, other than the Vines, may be sprinkled with liquid manure daily, neat stable or cow-house drainings being diluted with five times the bulk of water, and using about 3 gallons per square rod. The temperature of the house be 50° to 55° by artificial means, and 65° from sun heat. If the roots are outside they will need protecting with a good thickness of dry leaves, litter, or fern. This will secure to them a more uniform temperature, and is a necessity for preventing the soil becoming frozen. It is often better than fermenting materials that are allowed to become cold through not properly attending to them for maintaining the heat. Where the border has been exposed up to now it will be little warmer than the surrounding ground, and a good bed of fermenting material can be used with advantage, placing it on the border about 18 inches thick. This will to some extent warm the soil and encourage the growth of the roots, but it must be removed by the time the sun gains power to warm the ground, leaving enough for a mulch.

Houses from which the Grapes have been Cut.—Prune the Vines without loss of time, and when the cuts are dry dress them with best French polish, confining the dressing exclusively to the wounds. Early pruning not only avoids danger of bleeding, but insures complete rest, albeit the pruning buds profit in plumping and preparing for a good start. Cut to a sound round bud as near the base as possible. Some Vines, however, do not prove very satisfactory when closely pruned. The operator must act accordingly, and choose the second to fourth bud, or the best bud on firm well-ripened wood wherever situated. This will cause the spurs to become long, but that can be obviated by training a shoot from the base to displace it after bearing, and the Vine will be all the better for the extra foliage, showing it in the finish of the crop.

Remove all loose bark, avoid peeling and scraping into the quick or live bark, washing the rods with soft soap and water, and after thoroughly cleansing the house dress the Vines with an insecticide. If there have been any fungous pests use a solution of green vitriol (sulphate of iron), 1 lb. to a gallon and a half of tepid water (15 per cent. solution), applying with a brush to the rods. Clear away all loose soil or mulching, supply fresh lumpy loam in its place, and sprinkle about ½ lb. of the following mixture per square yard when the Vines are in need of substantial support. Dissolved bones, dry and crumbling, three parts or lbs.; muriate of potash, two parts; sulphate of magnesia, one part; air-slaked lime and soot in equal parts, four parts, mixed. If only moderate support be needed use half quantity, and supply the other about the time the Vines are fairly in leaf. Keep the house as cool as possible to secure complete rest.

Late Grapes.—Maintain a mean temperature of 50° for Muscats 5° less for other varieties that have finished late, with a dry atmosphere where such are hanging. Examine every bunch at least twice a week, and remove any decayed berries. Ventilate the house on fine days, and keep it closed when the weather is damp; but a gentle warmth in the pipes is necessary to prevent the deposition of moisture on the berries. It is hardly possible to keep Grapes in good condition beneath leaky roofs, and it is a capital plan to cut the Grapes, the ends of the stems being inserted in bottles of rain water secured in an inclined position, so as to admit of the berries hanging clear of the bottles. Some put a piece or two of charcoal in each bottle to keep the water sweet. Any dry room will be a suitable place where an equable temperature of 40° to 45° is maintained. Cutting the Grapes admits of the Vines being pruned, the house cleansed, and the rest thus given is very advantageous to the Vines, the house being kept cool and dry.

THE FLOWER GARDEN.

Tuberous Begonias.—Underneath stages, or any place where drip or much moisture reaches the pots, boxes, or pans in which the tubers are wintered are not the proper positions for storing these. Drip is particularly injurious, and may lead to the loss of numerous tubers, and, in any case, moisture is apt to promote an early weakly growth, whereas a later and much stouter growth is most desirable. It is advisable, therefore, to turn out tubers from boxes and such like, and after clearing much of the old soil from them, pack them more closely together in sand. They can then be stored in cool sheds, taking good care, however, to well protect them from severe frosts. March will be quite soon enough to start the smallest tubers in gentle heat with a view to growing the plants to a good size prior to bedding out, while strong old tubers may well be retarded till late in April. Propagating by means of cuttings is best practised during the summer, but old tubers with

several shoots may, after the latter are about 2 inches long, be cut into several pieces and started in gentle heat. The majority will survive and strong plants be had for the flower beds.

Raising Seedling Begonias.—Tuberous Begonias are effective either in masses of one colour or in mixture, nothing but a frost putting an end to their floriferousness. The erect flowering strains are the most showy, those with drooping flowers, though also pretty, being most effective in baskets and vases. The preference should be given to quite new seed, and this germinates most surely if sown before the bright sunshine and cold winds of February and March are felt. Added to this, early raised seedlings can be grown to a size large enough to bed out the same season, though it is not to be expected they will rival the two-year-old tubers. Sow early and sow thinly, and thereby avoid losing numerous seedlings by damping. Prepare two or three pans by draining them freely, and filling up firmly and evenly, with finely sifted compost largely composed either of very good leaf soil or peat. Avoid all use of sand in the compost, and more particularly on the surface. Gently moisten the soil, and then sow the seeds on the surface, but do not distribute any fine soil or sand over it. Set the pans on a mild hot-bed, cover closely with squares of glass, and shade heavily. There ought to be no necessity to moisten the soil; allowing it to become dry and then watering, however gently, being almost certain to dislodge either the seeds or the seedlings. In less than a fortnight germination should have taken place, when light must be admitted and the glass gradually tilted. Water very gently indeed and prick out the seedlings into pans of fine light soil before they become crowded.

Dwarf Lobelias.—These again can best be raised from seed, the strains as supplied by the leading seedsmen being as near perfect as they can be. The seeds being very small ought to be sown much as advised in the case of tuberous Begonias, and if not unduly exposed to a dry heat or strong sunshine will germinate quickly and surely. Sow thinly, crowded seedlings being peculiarly liable to damp off. Raise abundance of seedlings though, as it is not often too many are available. Cuttings of these Lobelias root readily in close frames or boxes placed in a fairly brisk heat, but not if they have been kept in a dry heat and induced to become hard. A newly started vinery, the plants not being placed very near to the hot-water pipes, is suitable for stock plants, and if there are enough of these the plan of propagating by division answers best. If kept in gentle heat the old plants will grow strongly, and directly the young shoots commence to emit roots near to where they start from is the time to divide them into as many pieces as possible. Being dibbled rather thickly into boxes of fine light soil and kept in gentle heat all will grow and be ready for temporarily bedding-out in frames in April.

Ageratums.—Though scarcely so true to name as Lobelias, very serviceable plants can yet be raised from seed, the strains including a good dwarf white. The seeds ought to be sown soon and somewhat thinly, covering very lightly with fine soil. It will germinate quickly if the pans or pots are partially plunged in a gentle hotbed and kept closely covered with squares of glass as well as heavily shaded. The seedlings being duly pricked out in boxes of fine soil, topped once, and then either given more room in other boxes, or better still, be temporarily bedded out in frames or pits, fine bushy plants will be ready for the flower beds when required. Cuttings of young flowerless shoots root readily in a moderately brisk heat, these, in their turn, affording cuttings so that a good stock of a favourite variety will be available in June. Introduce old plants into gentle heat to cause them to produce young shoots freely.

Various.—If a number of strong old plants of bronze, gold, and silver variegated Zonal Pelargoniums were lifted and potted before being badly injured by frost, these ought now to be introduced into a newly started vinery or other moderately warm house, where they will soon commence active growth and give a lot of good cuttings. Spring-struck cuttings of these are quite as serviceable as any autumn struck, but they must not be taken off the old plants before active growth of the latter has commenced, or otherwise the greater part will fail to root. Much the same remarks apply to the ordinary Zonals and the Ivy-leaved sections. Stock plants of Verbenas ought now to be given a shift into larger pots and placed in gentle heat, a strong heat being most objectionable, and a capital lot of clean sappy young cuttings will then result. Stock plants of Heliotropes, Lantanas, and Abutilons to be similarly treated, and if early cuttings of Fuchsias are required prune a few old plants and start them in gentle heat at once. There would be time to prepare a number of small pyramids for bedding out next summer. No cuttings being required, keep the old plants cool, and only moist enough at the roots to prevent shrivelling.

THE BEE-KEEPER

SEASONABLE NOTES.

WORK FOR THE NEW YEAR.

It may appear somewhat premature to suggest the carrying out of work in the apiary at this dull season. Still there are many things in connection with bee management that may now be profitably carried out. Some work if left until the days lengthen, bringing an increase in our daily duties, will probably be postponed; and thus the first step towards a successful honey harvest will have been lost.

It is an advantage at this season to take an inventory of all goods in hand, and to make a note of probable requirements for the coming year. If hives are required they may be made at home, and will then be in readiness when required during the busy season. These as far as possible should all be made of the same size, care being taken in correct measurements. This will save a great amount of worry and trouble when time is valuable. If made with loose floor boards so much the better, as it is then an easy matter to replace a damp board with a dry one.

Should no dampness enter the hive, the floor board ought to be well cleaned at least twice a year owing to the *débris* which will accumulate from the uncapping of the cells. Either spring or autumn is the best time to carry out this operation. All that is required is to place a clean board on the stand, and lift the hive bodily off the old one, which after being thoroughly cleaned may be used again. When worked on this plan the bees are not disturbed, the whole operation not taking more than a minute to perform. Compare this system with that which involves the cleaning of the boards attached to the hives, and the advantage of the former will be at once appreciated.

Hives should be painted with three coats of white lead outside; the inside is better not painted. If this is done a few weeks before using them, and they are stored in a dry airy place, the smell arising from the paint will soon pass away. Goods that it may not be convenient or possible to manufacture at home should be ordered of any dealer in bee appliances, who will supply them at a cheaper rate when ordered during the winter months. All will then be in readiness when required for use.

THE WEATHER.

The temperature being low bees are at rest and remain quiet in their hives. If the hives are rainproof no harm will happen to them, and if a supply of stores is within their reach they will come out strong and healthy in the spring.

To the ordinary observer the excessive rainfall may be somewhat oppressive, but to the bee-keeper it means no lack of moisture to the roots of the trees and plants, which will each in its season provide the sweet nectar and pollen without which bee-keeping would end in failure.

Already the early spring-flowering bulbs are well above the ground and growing freely. Many of the hardy plants and trees are forward; odd flowers may be seen on many, and should the weather continue open they will be fully in bloom earlier than usual, and bee-keepers may with confidence look forward to a more prosperous season in the year on which we have just entered.—
AN ENGLISH BEE-KEEPER.

EXPORTATION OF PLANTS TO ITALY.—We learn from a contemporary that Mr. Neville-Rolfe, the English Consul at Naples, states that the omission to include Great Britain in the Phylloxera Convention because of the British Isles being free from phylloxera, has caused a serious loss to that branch of British trade which occupies itself with the exportation of plants and grafts. To import plants into Italy from England requires the permission of the Italian Ministry, which must be obtained through Her Majesty's Ambassador at Rome. It is obvious, however, that the transit must be as rapid as possible, and any delay at the frontier must be guarded against. The permit must, therefore, be so timed as to arrive at the frontier as nearly as possible when the plants do, for if it arrives before it is pigeon-holed and forgotten; if after, the plants are kept waiting till it comes. In short, the present state of affairs gives much trouble, and is practically prohibitory of import. If it were possible for England to be included in the convention before next spring it is confidently asserted by Mr. Neville-Rolfe that an important market would be thrown open to English nurserymen. There is, he states, a large market in Italy for new sorts of Roses, bulbs, and grafts generally, there being many amateurs who spare neither labour nor money over their flower gardens, and many others, both professionals and amateurs, who would, if they could, introduce many plants, and especially many grafts, because the latter are portable. As to grafts, it is the custom to use in Italy much stronger scions than are usually adopted in England, and those who export them should recollect this.

TO CORRESPONDENTS

* * All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff after remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Pronunciation of French Names (J. H. S.).—If you send a list of names the matter shall be considered.

Gladiolus Nanceianus and G. Childs (A. L. Rosus).—These are presumably allied to the Lemoinei section, and succeed admirably either planted out or in pots, the size of the pots varying according to the size of the corms, about the distance of the diameter being allowed between each, and half that from the sides of the pot. Good turfy loam three parts, fibrous peat one part, and half a part each leaf soil or well-decayed manure and silver sand form a suitable compost, draining the pots well. Plunge in a cold frame till started into growth, and as they require more room move to a cool greenhouse, giving all the light possible, with air on all favourable occasions.

Implement for Placing Weed-killer in the Centre of Weeds on Lawns (J. H., Subscriber).—There are several implements such as you require, but we can only refer to those of firms which have advertised in our columns. 1, The "Acme" Automatic Weeder, manufactured or sold by the Acme Chemical Company, Limited, St. Stephen's Street, Tonbridge, Kent, consists of a steel cutting plate at the end of a tubular shaft or handle. The handle being filled with the "Acme" Weed-killer solution, when the cutting plate severs the weed at the root, by an ingenious mechanical action a small quantity of the poison is allowed to flow from the tubular handle on to the root of the weed. The weed is therefore cut and poisoned by one operation, so that it will never grow again. No danger to the useful herbage results, as the poison is put in the ground in very small quantities, and does not prejudice any, or very little, but the weed. 2, The Wikeham Patent Weed Eradicator, made or sold by the Boundary Chemical Company, Limited, 211, Great Howard Street, Liverpool, comprises a tubular staff (which may be used as a walking-stick), 36 inches long, fitted with a spike and self-acting valve. The upper part being filled with weed-killer, it is so arranged that by merely stabbing the point into the plant enough liquid is released into the tissues to destroy it. When not in use the point is protected by a cover, which may be screwed on or off as desired. The tube holds about three-quarters of a pint of liquid, and is sufficient to kill over 100 weeds at a cost of one farthing. The price of each implement is 8s. 6d., post free. We have used them with great success on lawns overrun by plantains and similar large weeds, getting rid of the latter, and securing a much better and easier-kept sward.

Ammoniacal Liquor for Disinfecting Subsoil in Cucumber and Tomato Houses (Cross).—Ammoniacal liquor from gasworks is, as you say, "strong and poisonous." It, nevertheless, is one of the most powerful fertilisers and very destructive of insect life, hence one of the best dressings for grass land, such as orchards and mossy meadows or pastures that harbour cockchafer, gardenchafer, rosechafer, and other grubs. In winter time it may be used in the proportion of one part gas liquor to two parts water; but during growing time one part ammoniacal liquor to five parts water is a proper solution. It browns the grass somewhat, but is followed by sweet herbage in plenty, which cows prefer to any other, leaving the other parts of a field for that to which the gas liquor solution has been applied. In reply to your questions, "1, Whether it is likely to kill the microbes?" if by microbes you mean the bacteria that act by converting ammoniacal substances into nitrates, or aid plants in assimilating or appropriating free nitrogen, we shall say no, for though the growth following the application of the ammoniacal liquor is due to the ammonia supplied, there is no cessation of their activity; but if you refer to eelworms you will find, if you like to try the experiment, that a one-third solution destroys them in a few minutes, sometimes seconds. The difficulty is to get the solution to them, as they are nobody knows where during the winter, therefore the substances intended for their destruction are uncertain in action simply on that account. "2, Whether it would be injurious to the roots of the Cucumbers supposing it was used a week or two beforehand only?" The answer is, it would not injure the Cucumber roots, but greatly benefit

them, as some ammonia would be evolved and pass upwards, besides the subsoil would be enriched for a considerable time. But the most danger would be in respect of the ammonia passing into the air and being confined in the house. This will kill everything in it if the vapour has free course upwards, but if covered with soil there would be an end of it; besides, the conversion would proceed rapidly in the soil and the smell soon pass off, then there would not be any danger. We should not use the gas liquor stronger than one part to three parts water. If you find anything alive in the soil of an animal nature after treatment please forward a specimen; but remember, proof must be given that the soil in which it was found had been thoroughly moistened with the solution. Usually eelworms come from places that have not been reached by disinfectants, and work to their heart's content on plants growing in soil from which the deterring effects have passed off, as is evidenced by the first crop not suffering, but the later ones being infested.

Tupa Feuilleti (A. J. B.).—A very distinct plant is the peculiar Tupa Feuilleti, and when growing vigorously, as it does in a few favoured districts, it is also very handsome. It requires, however, a rather warm

FIG. 14.—TUPA FEUILLETI.

and sheltered position, and even then needs careful protection in the winter, and some, to make it perfectly safe, place it in a greenhouse at that time of year. Under cultivation this plant attains a height of 4 or 5 feet, in exceptional cases even exceeding that, but it is often seen not more than 3 feet high. Its flowers, which are bright red, with the apex of the corolla strongly recurved, are produced on the upper portion of the stem from the axils of the leaves, and form a dense spike. It is a late-flowering plant, being frequently at its best in September or even in October. The woodcut shows the upper portion of a stem greatly reduced.

Mushrooms Discoloured (A. W. F.).—The Mushrooms appear affected by some noxious vapour, such as that of sulphurous acid gas in presence of a superabundance of moisture, which has destroyed the outer tissues in proportion to their tenderness, the buttons being blackened through and the larger Mushrooms affected on one side or some parts only. There is no trace of disease, the damage being wholly external and produced by something of a noxious nature, such as the fumes from live coal or cinders, which we have suffered from in cases where the Mushroom house has adjoined the stovehole and the furnace fires been raked out, causing the sulphurous fumes to pass through the imperceptible chinks in the wall separating the two places. The appearance of the Mushrooms exactly coincides with the injury caused by town fogs to tender vegetation, which have prevailed of late and done more harm than frequently occurs during severe frosty weather. The blackening sometimes occurs from an excess of carbonic acid (dioxide) gas, such as in very close and damp places, the Mushrooms being practically poisoned by their own emanations, for, though plants, they are of the class that live like animals, and as such require a

plentiful supply of oxygen. Thus the Mushrooms may only be suffering temporarily from the excessively wet and foggy weather, the house being kept very close and moist, this being so considerable as to remain on the Mushrooms indefinitely, and so interfere with the needful transpiration. In that case a little air would afford the desired relief, taking care not to dry the air too much or admit noxious fumes. The foregoing remarks are made in the hope of leading to a satisfactory solution of the injury or its cause, which is only ascertainable by a due diagnosis of the case and the circumstances, for there is no disease of a parasitic nature.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening.* *Dessert Pears cannot be named in a hard green state.* (J. R.).—1, Wellington, splendidly coloured; 2, a seedling from Blenheim Pippin; 3 and 4, unknown; 5, Glou Morceau. (B. C.).—1, Court Pendu Plat; 2, Bramley's Seedling; 3, probably a local seedling, useless; 4, Warner's King; 5, possibly Dr. Harvey; 6, Royal Russet. (E. D.).—All your specimens reached us in the form of pulp. They ought to have been sent three or four weeks ago.

THE AGRICULTURAL RATING ACT.

THERE is no doubt in the mind of any unprejudiced person that the industry of agriculture has fallen on evil times, and that the profits thereof are, even under the most favourable conditions, small as compared with those of many mercantile and manufacturing industries; but though agriculturists may be poor, they have pride enough to renounce any claim to what may be, and in fact has been, called an Agricultural Relief Bill. Farmers do not come for alms, but for justice. In the case of machinery, repairs have to be paid for by the user; when the machine is worn out it is sold for its value as old metal.

If this practice is applied to the human machines employed by farmer and manufacturer, then relief to the poor should come from the pockets of those who have employed them. If this principle were carried out, mills and ironworks, collieries, and similar hives of industry would pay poor rates according to the hands they employ rather than according to the annual value of the ground they occupy. As this might be objected to as a tax on labour, there are two alternatives which give to the land certain measures of justice; one is to charge all poor, highway, and other rates on an income tax basis—that is, in proportion to ability to pay. This would be the most satisfactory solution to the anomalies of rating, but the times are not ripe for its application.

The Government has adopted in its place a plan by which a portion (one half) of the rates on agricultural land is returned to the occupiers thereof, or rather is not collected, the remaining half of the local expenditure being provided for by grants from the imperial exchequer. This means when put in practice that it is paid out of income tax, for otherwise the rate of income tax would in all probability be reduced; thus the money at any rate falls on shoulders able to pay; whether in strict justice they are in all cases those who should pay we are not now prepared to discuss.

The Act as regards most of its clauses is a very simple one, but one portion of it has raised many points of difference between rating authorities—we mean the clauses defining what is and what is not agricultural land. We say defining, but to be correct we should say *not* “defining,” for this very important duty is left to the assessment committees to determine, subject to the approval of the surveyor of taxes for the district. The decisions of these authorities are subject to the appeal of any aggrieved ratepayer to the justices in quarter sessions, just as in any ordinary assessments.

The surveyors of taxes are themselves by no means unanimous in their ideas as to what should be included in the Agricultural Land Schedule, for whereas many would include horticultural, glass structures used by market gardeners, others object to do so and we think with considerable reason, for the buildings of the farm are as necessary a part of it as the structures of the market garden. The calf shed, which is the rearing house of the farm, is very closely analogous to the greenhouse in which are reared the Celery plants of the market gardener, and should be put in the same category, so that farm buildings being excluded nursery structures should be also.

Another point of difficulty has been the definition, for the purposes of the Act, of the word Park. The authorities appear to have adopted a proper view in considering grass land to be a park when it is used, with a house, for purposes of recreation rather than farmed in the ordinary sense of the term. On the other hand, land let to a tenant farmer, though it be situated around a mansion and be called a park, would not be rated as such, but as ordinary farm land. There are three requisites to constitute a park in law:—1, A Royal license; 2, Inclosure by a wall or fence; 3, Its occupa-

tion by beasts of chase, such as deer, and these strictly legal definitions would probably be taken as the legal meaning if it ever came to a court of law for decision.

Another point of disagreement has been the inclusion or exclusion of game. Where game—i.e., shooting rights—has been let with the land it has been rated with it as part of the land; but where it has been let separately and rated separately, whilst numerous authorities have decided that it shall not benefit by the Act, a few have been of a contrary opinion. We rather incline to look upon game as something quite apart from farming, and should prefer to see it rated as a means of recreation rather than as part of a farm, even if the tenant have the sporting rights in his own hands. He will benefit considerably by the Act, and can afford to pay full rates on sporting rights if others do the same. Thus, if no shooting at all be included in the schedule no one can grumble.

Many persons have an idea that the ratepayers will benefit under this Act during the current half year, but this is not so. True, a payment is to be made by Government to the local authorities before the 31st March next; but this money is intended for reduction of agricultural rates in the ensuing half year, and has been taken no account of in the estimates of the local authorities for the present half year.

WORK ON THE HOME FARM.

We have had more heavy rain, and the land is as wet as at any time since harvest; there are certainly less floods, but the soil is soaking with the moisture that may be wrung from it with very little pressure.

Manure carting having been completed for the present, many farmers are now short of suitable work. Plenty of employment can be found for the hands at fencing, thrashing, or amongst Potatoes, Carrots, and other roots; but, except the delivery of produce, there is little to do for the horses, and this state of things must prevail until we have a spell of fine weather.

Sheep on Turnips still have a bad lair, and we are sorry to say the roots are disappearing very rapidly. Sheep generally are doing well now, and their bill of health is much improved. We never saw so many cattle wintering out as in the present season, this being an arable district, and yard keeping under ordinary circumstances abundant. It is therefore evident that farmers anticipate a scarcity of keep, and are husbanding their resources. The pastures, being very soft, are much cut up by the hoofs of the cattle, and will have to be well rolled before spring.

Farmers intending to use basic slag for roots would do well to apply it early, so as to give it time to attain solubility before the plants require it. One of the objections to basic slag has been the difficulty of sowing it without a special drill. It may not be generally known that if water be sprinkled on basic slag from a rose at the rate of about a gallon to 1 cwt. and the slag be turned over immediately and well mixed, that it may then be sown by a man without any ill effects; in fact, he might almost sow it in his Sunday clothes. It should, however, be sown the same day as it is damped.

We see a neighbour planting Cabbages; his plants are small but healthy, and we are inclined to follow his example at once, if we can procure good plants. We generally grow our own, but ours have grown so badly, owing to the wet, cold autumn, that they are quite unfit to plant at present, being hardly large enough to handle with any ease. Wheat has made marvellous progress the last fortnight, and may be winter-proud even yet.

No. 865.—VOL. XXXIV., THIRD SERIES.

Barter's NEW HAND-PICKED PEAS.

As introducers of the Famous STRATAGEM, TELEPHONE, DAISY, and TELEGRAPH PEAS, we invite a trial of the following New Varieties, all of which represent the most advanced types in the different sections.

CARTERS SPRINGTIDE.

A first early Marrow Pea Height 2½ feet. Mr. W. A. COOK says: "It is very early; we gathered June 15th."

In Sealed Packets, 2s. 6d. per Pint, 4s. per Quart, post free.

CARTERS EARLY MORN.

Another fine Marrowfat, with very long pods. It was amongst the Earliest of the large podded section on our Farms last year. Height, 2½ feet. Stock very limited.

In Sealed Packets, 2s. 6d. per Half-pint, post free.

CARTERS ST. OSYTH GEM.

A cross between Chelsea Gem and Stratagem, combining the best points of both these excellent kinds. Very early. Height, 1½ feet.

In Sealed Packets, 3s. 6d. per Half-pint, post free.

CARTERS SEEDLING.

A New Maincrop Marrow, the result of crossing and interbreeding from the three popular varieties, Stratagem, Queen, and Autocrat. Its pods are amongst the largest we have ever seen, and we have counted as many as thirteen Peas in a pod. Height, 3 feet.

In Sealed Packets, 3s. 6d. per Half-pint, post free.

CARTERS DAISY.

Although this remarkable Pea has been out a few years, it is worthy a position in the most up-to-date company; and those who have not yet grown it should give it a trial. Dr. MASTERS, F.R.S., Editor of the *Gardeners' Chronicle*, who inspected our crop, reported fully upon its merits in a lengthy article. A customer recently sent in a pod containing twelve fully-developed Peas; and there is no doubt it holds the field as the longest-podded dwarf Marrow yet raised. Height, about 1½ feet.

In Sealed Packets, 2s. per Pint, 3s. 6d. per Quart, post free.

CARTERS MODEL TELEPHONE.

In Sealed Packets, 2s. per Pint, 3s. 6d. per Quart, post free.

CARTERS DANBY STRATAGEM.

In Sealed Packets, 2s. 6d. per Pint, 3s. 6d. per Quart, post free.

CARTERS MODEL TELEGRAPH.

In Sealed Packets, 2s. per Pint, 3s. 6d. per Quart, post free.

These are highly selected types of the originals, as introduced by us several years ago. Splendid for exhibition.

CARTERS MICHAELMAS.

As its names implies, this fine Marrow Pea is of the greatest service as a "Last-of-All" crop. It was well-grown last season in the Pea trials conducted by the Royal Horticultural Society, and the only late Pea considered worthy of their Award. Height, 2½ feet.

In Sealed Packets, 3s. per Pint, 5s. per Quart, post free.

Illustrated CATALOGUE, Gratis and Post Free.

THE QUEEN'S SEEDSMEN,

237, 238, & 97, HIGH HOLBORN,
LONDON, W.C.

Journal of Horticulture.

THURSDAY, JANUARY 21, 1897.

COMMEMORATING THE QUEEN'S REIGN.

FROM the Report of the Royal Horticultural Society for the year 1896-97 we find that the Society has decided to celebrate the occasion of Her Majesty's unexampled reign—not by a special flower show in London, but in a broader, more tangible, and more permanent way.

For ourselves, having in view the Temple Show occurring before the completion of the historical event, and the Queen's desire that there should be no premature celebration, we could not see the practicability of another show being arranged under the auspices of the Society in London of such magnitude as would befit the occasion, and which would command success.

So great and manifold will be the celebratory events in London this season that it would be a matter of extreme difficulty to provide a flower show in the metropolis on such a scale as to concentrate public attention sufficiently to accomplish the desired object. It might be done, of course, as if British horticulturists were to unite forces, and display to the fullest extent their resources, an exhibition of extraordinary magnitude would be produced, and this might—though the matter is problematical—"take the town by storm;" then, and then alone, would it answer the purpose of its production. Failure would be humiliation, and the project would be so entirely speculative that, having regard to weather contingencies among other counteracting influences, the endeavour could only be regarded as a venture, and the result essentially a matter of chance.

The Council of the Royal Horticultural Society has, and in our opinion wisely, decided not to play a game of chance over the great event of the year, and one which in all human probability will be memorable for centuries to come. Stand is taken on firmer ground, and instead of risking the investment of a large sum of money to be won in the way of prizes, spent and forgotten, something is provided that will possess much more than mere money value—an enduring and appropriate memento of an event which has no parallel in the annals of any nation—and will therefore be cherished by all on

whom it may be bestowed, and to whom it may descend—the "Royal Horticultural Society's Victoria medal."

This form of celebration has, we are informed by the report, been decided upon after considering "various proposals" which were found impracticable, and we cannot do otherwise than think the decision a happy one. Moreover, the proposal covers a wider area than any exhibition would, inasmuch as the recipients of the medal will not be confined to exhibitors of produce only. Some of these, it may be expected, will be recipients, for they have done much for the advancement of the art of which they are able exponents, and they will have another chance at Shrewsbury; but it is conceivable there are others who have done something too outside the competitive arena, yet diligent workers all the same in the wide domain of horticulture.

As the correspondence relating to the subject under notice cannot be otherwise than interesting to many readers we publish the following letters with which we have been favoured:—

Royal Horticultural Society, 117, Victoria Street, S.W.
December 18th, 1896.

SIR,—I am desired by the Council of the Royal Horticultural Society to ask you to lay before Her Gracious Majesty the Queen, Patron of the Society, a proposal which they beg leave to bring before their Fellows for the establishment of a medal or medallion in celebration of the attainment by Her Majesty, in 1897, of the sixty years of her happy, prosperous, and beneficent reign.

With Her Majesty's gracious permission and approval, the Council wish to name their medal "The Royal Horticultural Society's Victoria Medal;" and their proposal is that it should be awarded by the Society, "Honoris Causa," to a certain number of persons distinguished for their services to horticulture, or eminent in the science and art of gardening.

The Council express a confident belief that no such distinction exists at present, and that the institution of such a "Medal of Horticulture" would be received with marked favour by Her Majesty's garden-loving subjects. They therefore venture humbly to hope that their proposal may meet with Her Majesty's gracious consent and approval.—I have the honour to be your obedient servant,

(Signed) TREVOR LAWRENCE, *President*.

To the Right Hon. Sir Fleetwood Edwards, K.C.B.

Osborne, December 23rd, 1896.

DEAR SIR,—In reply to your letter of the 18th inst., which I have laid before the Queen, I am commanded to express H.M.'s regret that she can only refrain in this instance, as in all similar cases, from giving any personal opinion with reference to any specific proposal for the commemoration of the sixtieth anniversary of the reign.

At the same time the Queen has no possible objection to raise to the establishment of the medal referred to, or to the name that it is proposed should be given to it—and they would appear to be points that rest with the Council of the Royal Horticultural Society.—I am, dear Sir, yours faithfully,

(Signed) FLEETWOOD J. EDWARDS.

Sir Trevor Lawrence, Bart.

Clearer sanction on the part of Her Majesty could not be expected, indeed was not possible under the circumstances, and we have only to say now that we do not envy the Council of the Royal Horticultural Society the task of awarding this "Victoria Medal of Horticulture." We now pass to another most worthy proposition, and if it does not "catch on" we shall be both deceived and disappointed.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

The report of the Committee of this noble Institution, of which Her Majesty has been the Patroness for forty-five years, appears on another page. In that report it will be noticed that it has been "determined," or, to be accurate, determined to "endeavour;" but we think it is enough to "determine" that a "Victorian Era Fund" shall be established for the proposition to become an accomplished fact, especially as the object is to produce a fund sufficiently large to enable the Committee to give temporary assistance to applicants who are waiting to be placed on the pension list, and it is already "resolved" to send on June 21st next the sum of £5 to each unsuccessful candidate at the present election.

As we cannot make a stronger, and at the same time a more reasonable, appeal on behalf of this Fund than that of the esteemed Treasurer of the Institution, we have pleasure in publishing the following letter, as it will thereby be able to reach the eyes (and

hearts) of some readers, both gardeners and amateurs, to whom, it may be impossible to send a copy direct.

Royal Exotic Nursery, 544, King's Road, Chelsea, S.W.
January 14th, 1897.

SIR,—The extraordinary event—unique in our country's history—of Her Majesty completing, in June next, the sixtieth year of her beneficent reign, demands from us all, I venture to suggest, some special effort testifying to our deep thankfulness for the wonderful progress made in every way by our nation during the past sixty years, and for the many blessings we now so freely enjoy.

Animated by this feeling the Executive of the Gardeners' Royal Benevolent Institution (of which our beloved Queen has been the Patroness for forty-five years) have determined to endeavour to celebrate so remarkable an occurrence by establishing a special fund, to be called "The Victorian Era Fund," the income from which shall be devoted to affording temporary assistance to those applicants who are waiting to be placed on the pension list, and who have been subscribers to the Institution, every friend of which it is felt may be confidently relied upon to do their utmost to help raise a sufficient sum, the interest of which shall be devoted to the benefit of those who, when in a position to do so by becoming subscribers, did what they could to assist others.

The Committee consider that a sum of at least £5000 will be required to enable them to adequately carry out what they propose, and this in addition to the amount required to meet the usual yearly outgoings of the Institution, which exceed £3000 (the sum paid at the present time in pensions alone being £2840), and I, as Chairman of the Committee, appeal to every gardener and lover of gardens in the country to aid us in raising this sum—

First, By giving what he can himself and urging his brother gardeners to do the same.

Second, By earnestly appealing to all lovers of gardens to contribute something to this object.

And I feel certain that, if only every gardener will do what he can, the proposal of the Committee will be fully realised.

Any further information or details of the scheme will be most readily given, either by myself or by the Secretary (Mr. George J. Ingram, 50, Parliament Street, S.W., London), who will also be pleased to forward to any applicant collecting cards or boxes.

Earnestly begging you to give the matter your warmest support, I am, dear Sir, yours faithfully,

HARRY J. VEITCH, *Chairman of Committee and Treasurer*.

A notification accompanies the above appeal, which we also publish with great satisfaction—namely, that at the fifty-eighth anniversary festival dinner of the Institution, to be held at the Whitehall Rooms, Hôtel Métropole, on Wednesday, May 26th, 1897, and over which the Right Hon. Lord Rothschild will preside, the following

DONATIONS, &C., ALREADY PROMISED—

	£	s.	d.
His Grace the Duke of Westminster, President	100	0	0
The Baron Schöller, Vice-President	200	0	0
C. Czarnikow	50	0	0
N. N. Sherwood, Trustee (In memory of Emma Sherwood)	200	0	0
Harry J. Veitch, Treasurer	250	0	0
W. Sherwood (In memory of Emma Sherwood)	100	0	0
E. Sherwood	100	0	0
May Sherwood	100	0	0
George Monro	100	0	0
James Veitch & Sons	250	0	0
Thames Bank Iron Company	21	0	0
A. Watkins	10	0	0
James Hudson	5	0	0
J. W. Seden (Life Subscription)	10	10	0
J. Seden	2	2	0

It will be seen that gardeners have good and generous friends; and in no way can appreciation of the aid thus rendered be so acceptable to the donors as in the army of worthy workers themselves, doing what they can on behalf of an Institution that has done so much for so many to whom its help has proved a blessing in the past, and now, as it will in the time to come. We have yet another communication to append.

To my mind the most encouraging sign of all is to see the rising generation of young gardeners (page 17) supporting the Gardeners' Royal Benevolent Institution. These are the very men wanted to take a practical and enthusiastic interest therein. It is highly commendable and quite possible for every young gardener to save sufficient to make himself a life member before he qualifies for a head place. Doubtless if head gardeners would take up their case and act as treasurers, also choosing the right opportunity of representing the facts to their employers, assistance would be forthcoming in many instances through such a very commendable channel, thereby solving in the most practical way the problem of old age pensions, which agitates the minds of philanthropists and others at the present day.

Where such encouragement is denied when represented properly, there remains the Post Office Savings Bank, open to receive weekly contributions. In gardens where there is one of the official watering can boxes fixed I presume there would be no objection to the appropriation of the contents towards the same assistance.

There is a time in the probationer's life when he feels constrained to make some kind of provision for the proverbial rainy day; but as he knows little or nothing of this Institution he is easily attracted to the local lodges. I have not one word to say against them; on the contrary, some are known to be most worthy and well managed, but the prudent man will compare the results. In the "Royal," for one payment of 10 guineas he is eligible at sixty if needy, or sooner if incapacitated, to receive by right the sum of £20 per annum for life without further trouble.

In working up our Worcester branch it astonished the Committee to find the number of gardeners ignorant of the existence of the Institution. Personally, I should like to see the leading gardeners of each county, or federation of counties, form themselves into working committees with the intention of forming branches locally, to map out districts for each committeeman to canvas, and bring home to every gardener in the United Kingdom the claims and existence of such an Institution.

None could then plead ignorance, and I am almost autocratic enough to suggest a black register. If this county federation were done thoroughly I predict a result, both direct and indirect, that would justify the appeal now being made by our Treasurer, Mr. Harry J. Veitch, to establish a "Victorian Era Fund," and even exceed his most sanguine expectations.—WILLIAM CRUMP, *Madresfield Court*.

Allow me to congratulate those contributors to "The Young Gardeners' Domain," who, on my advice, are now, or about to be, Royal Benevolent Gardeners. There are few, in the bothy at least, but what to be so must entail some little self-sacrifice; not in itself sufficient to provide an excuse for standing aloof, but amply sufficient for us elders to honour their spirited action. May I, too, be permitted to express the wish that the governing authorities of that body could see their way to encourage young gardeners by admitting them as members at a reduced subscription of, say half a guinea per annum, until they attain the position of "head." Bravo! young gardeners. You have "done well, and not too soon," and afforded much gratification to—AN OLD BOY.

We may add that there is reason to believe that no form of commemorating the Queen's reign would be more in consonance with Her Majesty's feelings than such a Fund as that proposed by the G.R.B.I.; because the Prince of Wales, who has received many inquiries on the subject, has stated that, whilst giving no advice, he suspected the Queen would be best pleased with celebrations "which may tend to brighten the lives and ameliorate the condition of Her Majesty's poorer subjects." This is exactly the object of the Institution and its "Victorian Era Fund," and it is hoped it will be supported by the workers casting in their mites, as well as by the wealthy in the gardening community.

We should like to say also, in connection with commemorative proposals and decisions, how gladdening it is to find that a kindred institution which graces the horticultural world, the Royal Gardeners' Orphan Fund, which was established in honour of Her Majesty's Jubilee in 1887, has been enabled to admit all candidates to the benefits of the Fund during the present eventful year. The claims of this admirable charity must never be overlooked. In view of calls for the assistance of aged gardeners, widows, and orphans, also of the Indian Famine Fund, we begin to think that Mr. Wood's laudable endeavour to provide a Hall of Horticulture must stand over.

CHEMISTRY IN THE GARDEN.

THE rapid strides which scientists have made during the past fifty years in extending our knowledge of natural science is one of the most marked features of the present age. Science permeates every trade, and many are the facts which could be brought forward to show how valuable it is when combined with good practice.

What is science? The late Professor Huxley defined it as "organised common sense," or what, in other words, we should call "true knowledge;" and what can be more profitable to cultivators than true knowledge of the work in which they are engaged? There are two sides to all garden work—namely, the scientific and the practical. To know why we prune our fruit trees or pot and water our plants is the scientific side; to do the pruning, potting, or watering is the practical. Science and practice, therefore, go hand in hand, and cannot be separated.

Gardening, like agriculture, is an art which has been pursued from time immemorial. If practice alone could make an art

perfect, gardening and agriculture ought to stand out pre-eminently above all others. Do they? I think not.

Anyone coming in contact with continental gardeners soon notices how wide is their knowledge of natural science, and will then begin to understand why we, in some departments, are losing ground. To some extent we are not so fortunate as our continental neighbours, for while they have many institutions devoted to extending the scientific as well as the practical knowledge of their gardeners, we have but few. The books written on garden science are not many, and when we read the few there are, we soon find out how much we are depending upon other countries for our scientific information.

Chemistry is one of the natural sciences, and is the one most useful to gardeners and horticulturists; for by its aid we are able to prove—(1) What substances plants take from the atmosphere and soil to increase their growth; (2) of what soils consist; and (3) what ingredients manures contain that make them valuable to apply to the soil for the use of growing plants.

It seems at first difficult to grasp the fact, that so far as we know every substance in the world is made up of one or more simple bodies—called elements—of which about seventy are known to the chemist. Some of the elements are found in Nature in a free or uncombined state (*e.g.*, sulphur, iron, or gold), while others are united or combined to form compounds (*e.g.*, water, ammonia, or salt). I shall have constantly to refer to these two words—namely, *elements* and *compounds*, therefore let us clearly understand the meaning of them.

An element is a substance which cannot by any known means be made to yield anything other than itself; a compound, however, differs from an element, because it can be made to yield those elements which build it up. To make this clearer I might say that an element resembles a letter of the alphabet, while a compound would be similar to a word. If we take the letter "A," for instance, we know we cannot make it yield any other letter, but if we take a word we can make that word yield the letters of which it is formed.

Chemists have been able to tell us of what elements plants consist by carefully analysing them. The following elements have been found in all the plants that have been analysed:—Hydrogen, oxygen, nitrogen, carbon, sulphur, chlorine, phosphorus, potassium, calcium, magnesium, iron, and generally sodium and silicon. Vegetable physiologists took the subject up, and by growing plants in pure water or quartz sand, to which they applied compounds containing the above named elements, they found they were able to grow plants quite as successfully as they could in fertile soil. By leaving out any of the elements in the compounds they applied they were able to see what effect the deficiency had on the plant. These experiments soon proved that plants do not obtain their carbon from the soil, and also that, as a rule, they (plants) could be grown successfully when chlorine, sodium, and silicon were not applied. If any of the other elements named above were omitted the plants either refused to grow, or would only do so to a limited extent.

We will now proceed to the study of the different elements found to be essential for the growth of plants, for it is only by doing so that we can obtain that solid foundation upon which to build our knowledge of garden chemistry.

HYDROGEN (symbol H).—This element is a colourless invisible gas which is found only sparingly in Nature in a free state. Although hydrogen enters into the composition of all plants and the organic compounds found in them, they (plants) never absorb it as a gas, but always in combination with other elements which we shall subsequently consider. It will be sufficient at present to say that plants obtain their chief supply of hydrogen from water.

OXYGEN (symbol O).—This element is a colourless invisible gas found in Nature in considerable quantities, both in a free state and in combination with other elements. Indeed, it is the most abundant of all the elements, forming as it does one-fifth by volume of the gases which constitute the atmosphere, eight-ninths by weight of all the water which exists, and in combination with other elements it forms a large part of the solid mass of the earth.

Oxygen enters into the composition of all plants, and also into the compounds found in them. Plants would die, and seeds would not germinate if they were deprived of this gas. The reason of this is that during growth certain chemical changes are taking place during which oxygen is absorbed and carbon dioxide exhaled; energy is also required, and this is produced by the oxidation of certain compounds within the plants or seeds. This interchange of gases is called the respiration of plants. The principal source from which plants obtain hydrogen and oxygen is water. This being so, we see that plants have an unlimited supply of these two elements.

Water, as before stated, is a compound—i.e., it consists of two elements. The chemist uses a kind of shorthand to express the different elements and compounds. Water is expressed as H_2O . We have seen that H = hydrogen and O = oxygen, and as we have water expressed as H_2O , it signifies to us that this substance (water) is composed of two parts by volume of hydrogen chemically united with one part by volume of oxygen. But I have previously stated that "oxygen constituted eight-ninths by weight of water," there is evidently some difference then between the volume of these two substances and their respective weights.

Hydrogen is the lightest substance known, and is used in chemistry as the unit of weight. If we take equal volumes of hydrogen and oxygen gases and weigh them, we should find that the latter would weigh nearly sixteen times heavier than the former. As water consists of two parts by volume of hydrogen and one part by volume of oxygen, it must necessarily follow that water contains two parts by weight of hydrogen and sixteen parts by weight of oxygen. The weights of the elements always remain constant, so whatever quantity of water is taken the proportion of hydrogen to oxygen will be as two to sixteen or, what is the same thing, one to eight. There are many more interesting facts about water which we shall have to consider, but it will be better to leave them until we have finished with the elements.—W.D.

(To be continued.)

PRECEPT AND PRACTICE.

(Continued from page 24.)

MORE tuning of pipes? Patience, I prithee, young friend. Allow me to explain that our harmony must commence low down on the scale, and I would not thereby have you feel aggrieved at any apparent slight upon your intelligence. Any thoughts, precepts, or practice must now, at the start, catch the ear of the youngest of young brothers of the craft, for "as the twig is bent the tree's inclined." There is, too, a great deal of inclination in the "twigs," which a little observation will reveal. To illustrate this by a case in point. Last summer in a certain garden I was much amused to see a barrow piled high with weeds and rubbish, veritably zigzagging towards me, down one of the walks, the motive power being invisible until the near approach revealed young knickerbockers struggling manfully with the crowning glory of his hard hour's work. This boy, possessed of rare pluck, whose age does not exceed a dozen summers, in his unflagging zeal borne through the burden and heat of the long days, is typical of a sound embryo gardener; and this one is typical in all points of the British boy in his love of fighting, of sour Apples and similar luxuries. So much did the former predominate that a bad shot at another boy's head, which missed its mark to the detriment of some glass, has relegated him, much to his chagrin, to a winter's schooling, but his one desire is to be back in the garden, and he won't be happy till he gets it. With even the toil and drudgery part of garden work his heart, which is figuratively as big as his body, is in it. Lessons he hates with all the fervent hatred of a healthy young animal, and will continue to do so until their importance dawns upon his expanding mind, when, prompted by sound teaching and encouraged by good example, there is good reason for supposing that young knickerbockers now struggling under a load of weeds may eventually be fitted to bear the higher honours of a gardener's vocation.

Ambition, too, does not disdain knickerbockers, for I know that young B. looks on the bothy as a kind of earthly paradise; and as for the glass department, why he peers through the panes with longing eyes when the lads are syringing, for it must be—it is—some kind of angel's work. Now, I am quite sure that some of our clever contributors to "The Young Gardener's Domain" will be a little disgusted at the apparent puerility of this beginning; yet it is not so apparent to me, who could have gone farther back, in order to bring forward earlier aspirations marking the preliminary footsteps of a successful gardener. The boy who cheerfully turns the real drudgery into pleasure is not one to be burdened with many grievances later in life.

Probably a little careful selection at this early stage would result in weeding out some, at least, who eventually prove to be detrimental. There cannot be any severer test of a boy's fitness for gardening than his tractability to perform his allotted task unpurged. A labourer once handed over his little son to my charge, with the proviso that I might pull the boy's ears as often as I liked, and as long as I liked. "Pull 'em well, and he'll work well." Fortunately the boy did exceedingly well without, for I would be no party to such a bargain. I saw quite sufficient of that in one garden, where the ear-pulling was of almost daily occurrence, and the howls of the victims are borne on the breeze

of memory, to conclude that when it is necessary to resort to stimulants of that kind those boys are not born for gardeners, and that their object in life is for some other field, to which the sooner they are relegated the better for all concerned.

One intelligent boy for whom I went to some trouble in order to give him a start in the bothy, for which the parents expressed considerably more anxiety than the boy himself did regarding it, and rightly so, of course, as the introduction to a life of respectability, grievously disappointed me, for one fine day he marched away, discarding the blue apron to don the red jacket. Now if there are any boys filled with military or naval notions, or, indeed, any notions foreign to gardening, they have no right of entry into it, and any moral force of teaching or example, or physical force such as ear-pulling to subdue their chafing spirits, is simply a mistake. It is an intuitive love from which springs that "yearning ambition" my esteemed helper spoke of, that intuitive love of a garden and gardening which is able to satisfy the restless spirit of a boy and reconcile him to labour.

Of half a dozen boys who seek admission into a garden, or for whom admission is sought by their friends, possibly not more than one is worthy of being retained in it, but the one who is should have all the encouragement we can give him by affording him, as far as possible, variety in his work, and by letting him see that neither it nor he are beneath our notice. It is very crushing to these little men to be regarded as mere machines. There is, doubtless, a great responsibility attached to the hatching out of embryo gardeners, and those who feel that it is so will not lightly undertake the task.

Many kindly memories crop up of my treatment as a boy, and some that are not so, it is needless to say. The latter, chiefly of treatment from subordinates, to whose tender mercies the juveniles are too often submitted, shouting "boy" here and "boy" there; sending him for surreptitious cans of beer to refresh their thirsty cravings, and other disagreeable details too numerous to mention. How different was it at one place where our master, in his multifarious duties, always found time for a passing glance at the boy and his work, setting little crooked matters straight; not only showing how certain things were to be done, but explaining why they should or should not be thus done. How nice, too (apologies to Mrs. Scribe), to be addressed by one's name (most boys have one), and with what zest under these conditions the task was performed, and what a splendid thing it was to be a boy in that garden! This was, of course, the pre-bothyite period. To proceed farther under this head would probably lead to the inference that "An Old Boy" was rapidly drifting from first into second childhood. Sufficient has been advanced, I trust, to point a moral generally, particularly that conclusion I have long since arrived at—viz., that a little observation of "that boy" will, respecting his future as a gardener, easily solve the question now, "To be, or not to be."—AN OLD BOY.

(To be continued.)

BEGONIA GLOIRE DE LORRAINE.

PERHAPS on no class of plants has the art of the hybridist been brought to bear with greater force than on the Begonia, the result being that we have now variety sufficient to meet the requirements of the most fastidious. Amongst those kinds which are popular on account of their winter-blooming propensities, the one named at the head of this note may be well placed as one of the best. Being, comparatively speaking, new, this variety has not yet found its way into a large number of private gardens, but as it becomes more widely known and distributed there is no reason to think that it will not be grown and appreciated in most establishments.

Floriferousness is one of the chief qualifications of Gloire de Lorraine (fig. 15), and as it produces its charming rosy pink blossoms profusely right through the dullest time of the year, this adds greater weight to its value. The habit of the plant is pendulous and graceful, and when grown in shallow pans suspended from the roof of a greenhouse it is seen to the best advantage. As a plant for room decoration it may be strongly recommended, as the delicate tint of the flowers is particularly attractive under artificial light. The foliage is elegant without being unduly robust, but it is in the graceful habit and the abundant production of bloom that the usefulness of the variety mainly lies.

To keep up a constant supply of flowers through the winter months is a cause of anxiety to many gardeners; but by growing a quantity of this useful Begonia the anxiety may to some extent be lessened, as it is easily propagated and grown, well adapted for decorative purposes, and requires no more elaborate accommodation than that afforded in the ordinary greenhouse.—GROWER.

RAISING EARLY TOMATO PLANTS.

WHERE convenience exists for raising plants from seed, and insuring their progress in a satisfactory condition, the present is a suitable time to sow. The chief essentials in producing the plants are heat, moisture, and light. The two first are necessary for germination. When that has taken place light becomes also of paramount importance, in order to modify growth accelerated by the heat and moisture. Light is a main factor, too, in producing sturdy plants which will ultimately be fruitful. A judicious amount of air at all stages is beneficial. It must be afforded, how-

compactly, and level to within half an inch of the rim. Smooth the surface with the flat bottom of a small flower pot. Sow the seeds about an inch apart. It is quite unnecessary to sow closer, because, as a rule, every seed will germinate. Sowing thickly causes the seedlings to become weakened. The cotyledons or seed leaves, and the earliest of those following, require abundance of light. If the green surfaces thus developed cannot receive the light directly they strive to present themselves to as much as possible by growing towards it. This accounts for the weakening effect of being crowded. Therefore in raising plants, especially for early crops, avoid the seedlings touching each other from the first.

FIG. 15.—BEGONIA GLOIRE DE LORRAINE.

ever, in the early stages, so as not to prove harmful to the then tender tissues of the plants.

At this early period of the year a constant temperature of 60° to 65° is demanded by Tomatoes for promoting a free and steady growth. The seed will germinate best in a bottom heat slightly higher.

Varieties of some approved early types ought to be selected for early crops. Sutton's Earliest of All, the American variety, Early Ruby, and the useful, prolific Ifield Gem, are good well tried Tomatoes which invariably succeed with me. For sowing the seed prepare some light sandy material, consisting of loam, leaf soil and sand in equal parts. Mix well together, moistening if dry, so that the compost is in a friable condition. Warm the whole material to render it of a suitable temperature to sow the seed in. If, however, the soil is suspected of being but slightly infested with insects, grubs or worms, it will be desirable to heat it more highly in order to destroy them. The process of doing this may dry the soil too much, but by sprinkling over with water and mixing well, its former moist condition will be secured.

Drain a few clean 5-inch pots. Fill with the soil, shaking down

The sturdier they are kept the sooner they can be transplanted to other pots for strengthening.

In according the seedlings a light position a temperature must be provided for insuring sufficient warmth of the soil. This is a matter of importance during the early part of the season to bring the plants along. The sun has not much power to naturally raise the temperature inside glass structures, except for very brief periods, totally inadequate for the progress of the plants. Artificial heat must be relied upon. If a warm, dry shelf, moderately close to the glass, in a suitable temperature, affords the correct conditions, no better place can be found. It is better that the plants, however, should be some distance from the glass, if the position is light, rather than run the risk of their suffering from deficient heat.

After transplanting the seedlings improve considerably. For the first shift from the seed pots, the plants seem to do best when placed round the edges not less than 2 inches apart. Sink them low down in the pots, so that the seed leaves touch the soil when enough is filled in. The compost may be similar to what is used

for sowing. Being moist, as it should be when used, no water will be needed until root action has commenced. Sturdy, short-jointed growth follows, the plants shortly attaining sufficient roots for transferring to single pots. These may be 3 or 4-inch pots. Use less leaf soil in the compost, which should now be pressed more firmly round the roots.

At this stage a light position becomes still more important. The plants must have as much light as possible, with their tops near the glass so far as this can be done without withdrawing the roots from the influence of the necessary heat. In the month of March there is not much difficulty in securing a proper temperature on warm, light shelves in a heated structure. The advice chiefly pertains to an earlier date, when more care and attention is needed to secure the well-being of the plants.—E. D. S.

HORTICULTURAL HISTORY NOTES.

MEMORIES OF OLD CHISWICK.

PROBABLY the name of Chiswick is now to most gardeners principally associated with recollections of the gardens of the Royal Horticultural Society there situate, though, in fact, they are at Turnham Green but in the Chiswick parish. To enter fully upon their history and present state would occupy too much space; it would be also beside my purpose, and prove perhaps somewhat dry reading. Concerning their origin and early history, however, a little may be said, since the place is intimately connected with horticulturists who linked the Georgian and the Victorian period, and formerly were workers or learners there. It was a great change the removal from the small experimental garden on the border of Kensington to the extensive ground which the Society has had under its charge for nearly seventy-four years. A commencement was made in 1822, but two years elapsed before the ground was properly laid out, when of the available space about 17 acres were devoted to fruit and vegetables, and 14 acres to flowers, ornamental trees, or shrubs. From the beginning the fruit department was one of the chief features of the gardens.

Loudon, surveying the place subsequently as a friendly critic, objected to the formation of the arboretum in one large clump; he would have preferred if this had been carried all round the circumference of the gardens, its monotony broken by occasional flower beds. Also, he disapproved of the scattering of the houses and conservatories over the grounds, considering it better to have these as a group or a chain in the central area. Then, in the original plan of the gardens, the communications between the different portions were not made convenient to workers and visitors. Some of Loudon's hints were taken advantage of during after alterations. The illustrious President of the Society (T. A. Knight, Esq.), well remembered by his numerous writings on horticulture and kindred topics, took an active part in the arrangement and administration of the Chiswick garden, being ably supported by Mr. Joseph Sabine, then the Hon. Secretary. Another individual, for many years associated with the fruit department, and who entered upon his duties in 1827, stands high on the record; this was Mr. Thompson, a man possessed of a knowledge of fruits and of a skill in their cultivation which few have equalled. Trial grounds were set apart for Apples, Pears, Plums, Cherries, and one for general fruits; especial attention was also given to varieties of the Strawberry.

At first, a good deal of forcing was carried out here, with Pines, Peaches, Figs, and other things, but subsequently this was considered neither profitable nor instructive, and it became at last a minor item in the annual work. Proving and testing Vines has been carried out regularly from the beginning, not merely to the benefit of gardeners, but to that of the public also. When Mushrooms, again, were little cultivated generally, various useful experiments in growing them were made at Chiswick. Valuable information concerning manures has been published in past years, from the results of trials here, by which both agriculture and horticulture have been gainers; one of the Society's supporters, who took much interest in these, was Professor Solley.

From almost every part of the world seeds and slips arrived at the Society's gardens, these being obtained by an admirable system of exchange, and by correspondence with establishments or individuals. After experimental cultivation new and valuable species were distributed to members, and then gradually spread over our islands. Collectors were employed whose researches have left an abiding memorial in the plants they procured. We may recall the names of Hartweg, who explored Mexico and adjacent countries; of Fortune, who visited China; and of Douglas, who introduced more than 200 species, chiefly hardy. Amongst these are *Ribes sanguineum*, *Berberis aquifolium*, *Mimulus moschatius*, a number of Conifers, and many good annuals, such as *Nemophila insignis*. One thing that attracted the notice of visitors thirty or forty years ago was the display of climbing plants, the growth of which was

managed here so as to closely imitate Nature in a manner which had been previously unknown about gardens. At the commencement of Her Majesty's reign the principal conservatory was built from the designs of Alfred Ainger, Esq., the internal arrangement being then somewhat novel. It has since furnished hints to the erectors of similar houses.

Let us, however, pass on to Chiswick itself, which was notable for its gardens and orchards a good while before the Society added to its renown. Originally, they say, just a fishing village. This seems laughable now, yet there was a time when the fishery of the Upper Thames was important. There is a popular idea that the name of it was once Cheesewick, because a fair for cheese was held on the Mall. Really it is Saxon, and refers to the sandy undersoil upon which the village rests. The gravel and sand render drainage, except for surface water, unnecessary. About this is a good loam, not too stiff for vegetable crops, nor too light for most fruit trees. Primitive Chiswick had no roads, but when these were opened up the eligible nature of the place led to its being selected for market gardens and orchards, many of which have now been transformed. The way in which houses were built about new Chiswick upon Cabbage fields and Asparagus beds, with no proper foundations, and in defiance of all hygienic rules, I myself have witnessed. The air of the neighbourhood cannot but be pure since it is changed four times daily by the tidal rise and fall, yet the position of Chiswick gives it much heat in summer, while the winter and spring frosts are apt to be severe.

Chiswick began to appear prominent amongst London suburbs when Lord Burlington, well known in connection with a Piccadilly mansion, acquired a large extent of land there, built a residence, and laid out gardens. Kent, the pioneer of landscape gardeners, according to some, was employed by his lordship, and the Italian style was followed with some variations. We cannot walk about the grounds now and not be arrested at nearly every step by trees which tell of planting carried out early in the Georgian era. There was once an avenue of six Cedars of Lebanon, but one has perished; the five remaining must be about 80 feet high, and spread out handsomely. Near them, at a more recent date, have been planted some Deodars, which are already of good size. Other Cedars flourish in another part, near what used to be called the Poet's Corner, in proximity to which are fine Evergreen Oaks. Adjacent are masses of Rhododendrons, many of age, and some have extended themselves largely by layering. Numerous are the venerable Hollies and Yews; of the latter tree there is a splendid double hedge which screens Napoleon's Walk. Not far from this are two Portugal Laurels, the unusual proportions of which attract notice, but in fact it is an assemblage of the species through layering, and the Bay ground near has always had a repute for its varieties of that group. There are some handsome Magnolias and deciduous Cypresses; also amongst the older trees we notice specimens of the Hornbeam, Birch, Wych Elm, Plane, Oak, and Lime.

The Lime avenue, indeed, has been a permanent link between the Society's gardens and Chiswick House, since it conducts visitors to both, and throughout the history of the gardens the Dukes of Devonshire have cheerfully allowed the public at specified times to admire the beauties of the private demesne adjacent. It was in the grounds of the Horticultural Society that Paxton formed his acquaintance with his ducal patron, which was thereafter to prove so full of results. It was about the middle of the present century that this Duke planned and carried out an entire re-arrangement of the flower gardens at Chiswick, also erecting a new range of hothouses. He made large addition to that part of the shrubberies that was devoted to the Pine tribe. A reduction was carried out in the number of beds containing mixed herbaceous plants, and the system adopted of filling most of the beds with one species each. The Pansy and its allies were favourites here formerly, and a considerable show of them used to be made in the early months. To the Camellia and Fuchsia special prominence has been given, indoors and out; Pelargoniums also have been much studied at Chiswick.

At Corney, above Chiswick, is a garden belonging to the Devonshire estate, which has some notable specimens of *Pinus pinea*, the seeds of which were brought from Mount Etna by one of the Dukes. There are several remarkable Thorns and large Portugal Laurels, specimens of *Liquidambar styraciflua*, and Tulip Trees which could hardly be matched anywhere. Higher up still, at the Grove, on the lawn there were (and I hope yet remain) some Spanish Chestnuts of unusual height and age; several of these varied in girth from 24 to 27 feet.

The Bagleys, princes amongst suburban market gardeners, had at one time much ground about Chiswick, so, too, had Jessop and Mills. Extensive, again, were once the orchards belonging to Dancer, who raised splendid crops of Apples and Plums. The locality was not suited for most Pears, and Strawberries were never grown so largely about Chiswick as at Fulham.—J. R. S. C.

HYBRIDISATION OF ROSES.

[The N.R.S. Prize Essay, by WALTER EASLEA. R. Clark, Limited: Edinburgh, 1896.]

THE "Rosarian's Year Book for 1897" tells us:—"In 1896 Mr. A. H. Grey offered a prize of £5 for the best essay on the Hybridisation of Roses," and that "the prize was awarded to Mr. Walter Easlea for a very carefully considered brochure. He is the son of one who was associated with the late Mr. Laxton in the various experiments on hybridisation he carried out both at Stamford and Bedford, and he is moreover engaged at Messrs. W. Paul & Son's, at Waltham Cross, so that he has had much theoretical and practical training for the task which he undertook."

It is certainly exceedingly well executed. Our readers cannot do better than invest in it, nor will they regret, even though "bang goes saxpence." It is worth the money and more. A large portion of course belongs specially to the hybridiser, but there is much also that is interesting to the average rosarian. "*Pocula nascitur, non fit*;" and so, we incline to think, is it with the originators of new Roses. We too have aspired, and essayed; but the pollen, and the stamen, and the pistil never seemed to be of one mind at the critical moment. A calm old age has induced encouragement rather of other operators.

Mr. Easlea gives his subject three heads and an application. Under conceivable circumstances two are sufficient; but we would not willingly lose one of these three—1, The Art of Cross-fertilisation. 2, Some Past Results. 3, Improvements Desirable. Then the seed and its treatment. This last we shall skip, as is usual with most morals. The three former contain also much of general interest. As to "the Art," he brings forward some highly respectable names, asserting that "Nature intended flowers to be cross-fertilised for their own good, and that sometimes the vigour is thus increased fiftyfold." Immortal Will has a word to say on this, as well as on almost every other subject.

"This is an Art
Which does mend Nature—change it rather; but
The Art itself is Nature."—(*W. Night's Tale*.)

Says Mr. Easlea, "We need to infuse new blood into our Roses at the present day, as our horse-breeders and farmers are doing with their horses, cattle, and poultry. The late Mr. Bennett once told me that he believed he could induce any variety of Rose to seed." This is, however, by no means a usual experience in our climate.

Mr. Easlea suggests an airy light glass structure, to be erected in the form of a lean-to, facing due south, and then instructs the happy owner exactly how to proceed. As there is not many a Lord Penzance, and very many weaker brethren, it may be well now to hasten on to his second ("Past Results") discussion. This chapter is exceedingly interesting, and with old rosarians will revive many touching reminiscences. Dear Général Jacq! what an extensive progeny indeed he sees around him! And, what is puzzling to express, he seems sometimes to have been mother as well as father. "Seed parent" in the case of Charles Lefebvre and Mons. Boncenne; "pollen parent" to R. M. Henriette, Albert la Blotais, Max Singer, and others.

Jules Margottin is mentioned next. "A wonderfully wide range of colour has characterised the offspring of this variety—Castellane V. Bouyer, Annie Laxton, and many others." Victor Verdier has been also an excellent seed producer; Etienne Levet, Marie Finger, S. M. Rodocanachi, and other high-class Roses all claiming his parentage. In some cases several generations can be traced. That huge La Reine, the ruin of our "boxes" in our "sallet" days, produced Anna de Diesbach, a much mitigated representation of herself; and this, again, Ulrich Brunner, which has been pronounced on high authority our very best all-round Rose, taking colour, character, and foliage into consideration. The good old Glory has a progeny which would require an article to themselves, R. M. Henriette being the result of her marriage with Général Jacqueminot; those excellent Roses Belle Lyonnaise and Madame Bérard are also her offspring.

Amongst Tea Roses Madame Falcot has been a useful seeder, being the parent of Perle des Jardins, Hon. Edith Gifford as a grandchild, and that almost best all-round Tea, M. V. Houette. From Devonensis has come the new and highly esteemed K. A. Victoria. The little-known Madame de Tartas gives the excellent Madame Lambard, and the still more famous Cheshunt Hybrid, this latter being the result of a cross between Tartas and C. de Rohan. Maman Cochet, the best new Tea, descends, we are told, from that Rose treasure Catherine Mermet. To this list must be added Isabella Gray, the parent of the great Maréchal Niel; "very much," says Dean Hole, "as if a dingy old sparrow had hatched out a canary!"

But results must be left for endeavours. The third heading, "Improvements Desirable," makes the mouth water, but the experienced grower also to remark inwardly something or other about "hope deferred." These improvements are suggested with a light heart, their realisation would be hailed with a thankful one. "In the first place our

collection of show Roses is sadly in need of a good vivid poppy scarlet." The possible parents of such are suggested. "Large, well shaped, very dark, almost black, Roses are wanted." "A pure white Marie Baumann would be a welcome addition to our seventy-twos."

"Among Tea Roses and H.T.'s, take, for instance, such splendid varieties as Maman Cochet and K. A. Victoria. We require more Roses of this type, and, if they can be obtained in pure yellow, bronze, and Ma Capucine colour, what a glorious feast is in store for us!" "A white Maréchal Niel is announced, but what a lovely acquisition would be a Maréchal of the colour of W. A. Richardson. Mr. Bennett informed me on one occasion that he had induced Maréchal Niel to seed, therefore there is hope for us."

We had marked further passages, but perhaps are now verging rather too nearly on Utopia.

"Utopia is a pleasant place,
But how shall we get there?
Straight down the crooked lane,
And right round the square."—HOOD.

We conclude with a very happy latter-day suggestion, though most of us have still to make full acquaintance with the couple suggested to be affianced. "Would not a cross between Crimson Rambler and A. S. Grey produce some novelties in the way of climbers?" Do, Mr. Easlea, delight us with the realisation, as well as suggestion, of some of these only too seductive fairy visions.

COLOURED-STEMMED RUBUS.

ALTHOUGH most of the species which form the genus Rubus are decidedly more ornamental during the summer and autumn than in winter, there are several which are most conspicuous during the latter season, the species referred to being those with coloured stems. Some of these are R. biflorus, from the temperate Himalayas; R. leucodermis and R. occidentalis, natives of N.W. America; R. lasiostylis, from China; and R. neglectus and R. racemosus. The colour of these plants is due to a glaucous bloom which covers the stems, in some cases so thickly as to give the plants the appearance of being covered with a coat of white paint:

By far the most conspicuous of those mentioned is R. biflorus. This forms a strong-growing bush, somewhat resembling in habit the common Blackberry. R. neglectus is also very good; the coating of bloom is thinner than in the preceding, and does not altogether hide the reddish-brown bark beneath. The habit of R. occidentalis is similar to that of the two foregoing, and the stems have a rather thick coating of bloom. R. leucodermis is more rambling, and much weaker than either of the former. R. lasiostylis and R. racemosus are stiffer in habit than the former, resembling more the growth of the Raspberry.

Like most other coloured-stemmed plants, the best colouring is obtained from young quickly grown shoots, consequently they should be planted in good soil, so as to insure strong growths each year, some of the old growths being cut away annually.—W. D.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 12TH.

SCIENTIFIC COMMITTEE.—Present: Mr. Michael (in the chair); Mr. Lynch, Rev. W. Wilks, Dr. Russell, Dr. Bonavia, Mr. Douglas, and Rev. G. Henslow (Hon. Sec.).

Tomatoes Diseased.—It was reported from Kew that the specimens exhibited at the last meeting were too much decayed to be able to ascertain what fungus, if any, had caused the disease.

Senecio multiflorus, Hybrids.—Mr. Lynch exhibited a number of specimens which he had raised by crossing S. multiflorus with various forms of the garden or cultivated Cineraria. The colours much resembled those of the latter plant, the foliage being intermediate, and the height about 3 feet. All but one had S. multiflorus as the female parent, the results showing therefore great prepotency on the part of the male (Cineraria). S. multiflorus was first introduced from the Canaries in 1855 ("Bot. Mag.," tab. 4994, *Doronicum Bourgei*). It was subsequently lost from Kew and reintroduced to Cambridge by Mr. Gardener in 1895. Some of the flowers showed a peculiar circular white spot on the red tip of the petals.—(*Gardeners' Chronicle*, Jan. 16, 1897.)

Cineraria cruenta.—Mr. Douglas said that he is raising seedlings of this plant, in order to see if it varies towards the cultivated forms without being crossed. Mr. Lynch observed that C. Tussilaginis was a species which apparently most nearly resembled the cultivated Cineraria.

White Narcissus, Artificially Coloured.—Dr. Russell exhibited some cut flowers of white Polyanthus Narcissus, which he had placed in solutions of acid red magenta (Judson) dye, and in acid green. The colours had traversed the fibro-vascular cords, and then spread over the intermediate tissues, forming a border round the ends of the petals. He proposes investigating the matter to try and discover the general nature of those colours which will act in this way. It took from twelve to fifteen hours to infuse the perianths. Mr. Henslow remarked that John Laurence in his book on gardening (1726), says that people in his day used to colour flowers by letting the roots lie in a solution of the lees of claret.

WEATHER IN LONDON.—Those who accept the presence of snow on the trees, the houses, and the roads as being synonymous with winter would be satisfied on Saturday and Sunday last. On the first-named day there was a fairly heavy fall, the snow remaining over Sunday, on which night a rapid thaw set in. Both nights brought sharp frosts, but Monday evening saw a reduction, and on Tuesday night it was wet and mild. Rain fell slightly at the time of going to press on Wednesday.

WEATHER IN THE NORTH.—The weather for the past week has been pleasantly seasonable, the days and evenings being calm and bright, and frost of varying intensity prevailed throughout; 4° were registered on the morning of the 16th, 11° and 14° on the following days. On Tuesday morning there was a slight appearance of a change, 10° of frost being recorded.—B. D., *S. Perthshire*.

CARDIFF GARDENERS' ASSOCIATION.—The opening of the Session 1897 took place on Tuesday, January 5th, when a lecture was delivered by Mr. W. W. Pettigrew, gardener to the Cardiff Corporation, on "Process of Fertilisation," illustrated by limelight. Other evenings will be devoted to "The Culture of the Carnation," by Mr. Pike, January 12th; "Vine Culture," by Mr. Tucker, January 26th; "The Fuchsia," by Mr. J. Julian, February 9th; "Carnivorous and Insectivorous Plants," by F. G. Treseder, February 23rd. The Hon. Secretary is Mr. W. J. Hockey.

SEED DISTRIBUTION.—The whole subject of the methods by which seeds are distributed is attracting considerable attention just now. It seems almost impossible to construct any general law by which to explain the reason for things in nature. It does seem, for instance, safe to say that wings are given to seeds to enable them to fly far away from the parent tree, and thus extend the area of territory occupied by the species. But in many of the large-seeded Pines—the Linden and others—the hollow seeds only are the ones blown away. The solid, perfect seeds remain around the parent tree. The objectors to everything argue that wings are given to fan out the light, useless material. But, says an American contemporary, this surely cannot always be.

HAMPTON COURT GARDENS.—We learn that Mr. Archibald Graham, who has been some twenty years superintendent of these famous public gardens, and who by virtue of advanced age would soon have been retired, has resigned the post, and will shortly quit Hampton Court. He is to be succeeded by Mr. Gardiner, for some time superintendent of Greenwich Park. This gentleman will find in his new sphere wide scope for the exercise of his talents in flower gardening, for that is here the dominant attraction, so far as the grounds are concerned. There is especially room for the introduction of hardy border flowers to a much greater extent than now is found. The staff left by Mr. Graham is a good one and well up to the work, so that any new superintendent will at the outset find his responsibilities materially lightened. Hampton Court yearly grows in popularity, as indeed it is a beautiful place, and now that the great Home Park is open to the public there is no more attractive place of resort that is fully public in the kingdom. It is stated that locally a testimonial to Mr. Graham is being prepared.

WINCHESTER GARDENERS' ASSOCIATION.—On Tuesday the 12th inst., at a meeting of the above Association, Mr. Curtis, gardener to W. F. G. Spranger, Esq., Springhills, Southampton, read a paper on "Tomato Culture under Glass." The remarks were illustrated with plants from seeds sown thickly, from seeds sown thinly, and rods a year old, from which fruit was cut at the end of December. The paper was both practical and instructive. Questions were invited, and the number asked proved that the subject was one in which many members were interested. Certificates of merit were awarded to Mr. Munt, gardener to Mrs. Warner, Salcot, for three plants of *Primula Prince Arthur*, and three plants of *Solanum capsicastrum*, which were very dwarf and well berried; Mr. Crook, gardener to A. R. Dyer, Esq., Palm Hall, for three *Primulas*, *alba plena*, and a plant of *Cyclamen White Butterfly*; Mr. Adams, gardener to Colonel Dickins, Blackbridge House, for three plants of *Primula sinensis fimbriata*. Several other exhibits were very highly commended.

GARDENING APPOINTMENT.—Mr. Henry Haines, head gardener for the past nine years at Shottesbrooke Park, Maidenhead, has been appointed in the same capacity to W. N. Diggle, Esq., Efford, Lymington.

THE SILVER WEDDING OF MR. AND MRS. T. WHILLANS, Blenheim Palace Gardens.—This was celebrated in a very pleasant manner on January 6th, when the Duke of Marlborough kindly sanctioned the use of the capacious corridors of the south block of greenhouses, which were prettily decorated, for the purpose of entertaining the many friends, including the principal domestics at the palace, who assembled in goodwill and amity to the hosts to honour the event. A most enjoyable evening was spent, and for those who were present will form a very pleasant remembrance. Mr. and Mrs. Whillans were the recipients of numerous tokens of friendship and kindly congratulation, amongst others a handsome silver cake basket, given by the garden employes, which will no doubt be regarded as a most sincere expression of kindly sentiments.

THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—At a meeting held January 12th, Mr. Chas. Lawton in the chair, a paper was read by Mr. Peake, Superintendent of the Public Parks and Gardens of Hull, on "Trees in Towns." The essay was confined mostly to the planting and management of trees in streets, and the varieties best adapted for the low-lying town of Hull, the appearance of which has been considerably improved during the last quarter of a century by the large number of trees which have been planted, and now much admired, and a source of great pleasure to the inhabitants. Great credit is due to Mr. Peake, under whose superintendence the work proceeded, for bringing about such successful results. Votes of thanks to the essayist and Chairman concluded the meeting.—F. L. T.

READING HORTICULTURAL SOCIETY.—The annual general meeting of the Reading and District Gardeners' Mutual Improvement Association was held in the Club Room on Monday, January 11th. Mr. T. Neve, the Chairman of the Association, presided over a large gathering of members. After the report and balance-sheet, which were of a very satisfactory character, had been read and adopted, the following members were elected to fill the various offices during the ensuing year. President, Mr. C. B. Stevens; Chairman, Mr. T. Neve; Vice-Chairman, Mr. E. Dearlove; Librarian, Mr. James Martin; Assistant Librarian, Mr. E. Dore; Treasurer, Mr. W. Phipps; Secretary, Mr. J. Pound, jun.; Committee, Messrs. F. Bright, C. Burton, R. Butcher, R. Chamberlain, H. G. Cox, B. Dockerill, H. Farey, W. Goddard, R. Hearn, G. Hinton, J. Pound, G. Smith, W. Smith, T. Turton, H. Wilson, and J. Woolford. A very hearty vote of thanks was passed to the retiring President, Mr. Arthur W. Sutton, for the great interest he had shown in the Association during his term of office. A beautiful collection of *Primula obconica* was shown by Mr. Townsend, gardener to Sir William Farrer, Sandhurst Lodge, and was greatly admired.

HORTICULTURAL CLUB.—The monthly dinner and conversation took place at the Hotel Windsor on Tuesday, 12th inst. The chair was taken by Mr. Harry J. Veitch (Vice-Chairman of the Club). The subject for discussion was "The Proposals for Horticultural Memorials of the Queen's Reign," which was opened by the Secretary, Rev. H. H. D'Ombraim, who passed in review the various proposals which had been advanced in the gardening papers, and expressed his opinion that not one of them was practicable, and that as far as a horticultural institute, of whatever character it might be, was concerned, there was no situation in London that could be considered eligible. What was required was not so much a hall where large shows could be held as a home where such fortnightly meetings as those of R.H.S. could be held, together with some suitable offices for Committee meetings and horticultural gatherings, which must be held in a central position alike suitable for the provinces and the suburban exhibitors. A discussion took place, and the general opinion was that with the air full of schemes for the popular celebration of the sixtieth year of the Queen's beneficent reign, the year 1897 was not a good time to launch a scheme for the national benefit of horticulture, more especially after Her Majesty has herself indicated that what would be most acceptable to her would be the strengthening of the nursing institutions, hospitals, and other works of mercy for the relief of the suffering and poverty stricken masses of the people, and horticulturists would have a good opportunity presented to them of following this particular line in strengthening the new "Victorian Era Fund" about to be raised by the Gardeners' Royal Benevolent Institution, particulars of which will shortly be announced.

— **DEATH OF MRS. JONES.**—Numbers of friends of Mr. T. Jones, who was for many years Her Majesty's chief gardener at Frogmore, will mourn with him on the death of his much-loved wife. Mrs. Jones, we are informed, died at Pattingham, near Wolverhampton, after a long and painful illness. She will be well remembered by many old friends of Mr. Jones for her quiet, happy way in making them at home during occasional visits, and by the unostentatious yet genuine manner in which she dispensed hospitality. Mrs. Jones was in all respects a most excellent gardener's wife, and we are not surprised to learn that Mr. Jones feels his bereavement most keenly.

— **JADOO FIBRE.**—The introduction of Jadoo fibre by Col. Halford Thompson a few years ago was not regarded by many persons with much favour. Events have proved the merit of the material, and the company that was promoted some time back now finds itself hampered by lack of funds, the business having increased to such a surprising extent. Such being the case, it has now been decided to increase the capital to £50,000 sterling, which will allow the Directors the needed scope for extension. Col. Thompson is the Chairman of the Board, of which P. C. M. Veitch, Esq., is a member. For other particulars, see our advertisement columns.

— **POTATOES FOR EXHIBITION.**—This is what I read in one of our great weekly newspapers the other day, under the name of a reputed leading horticulturist. I could but fancy that our old friend has been playing Rip Van Winkle:—"Best six varieties for exhibition—Snowflake, Schoolmaster, Garibaldi, Red Emperor, International, Kidney, and Ashtop Fluke. Best two white rounds—Porter's Excelsior and Schoolmaster. Best two coloured rounds—Red Emperor and Beauty of Kent, or Grampian." Just so, twenty years ago; but now of all the varieties mentioned hardly more than two are found in commerce. Not one of the fine Potatoes of to-day gets mention. Clearly it is a case of twenty years' somnolence.—**SOLANUM.**

— **SINGLE DAHLIAS.**—It is curious to watch the changes of fashion in regard to popularity in flowers. A few years ago there was a great rush for single Dahlias, and they were really beautiful; of late years, however, they are rarely seen. The misfortune with the old Dahlias frequently is they bloom rather late in our climate, and are no sooner in full force than the frost is ready to dispute possession with us. In the Old World the Dahlia is yet popular. In France they have succeeded in getting varieties of Dahlias with new double disc flowers. Usually, where the Dahlia is improved, the disc florets become strap-shaped.—(*"Meehan's Monthly."*)

— **BERLIN GRAND EXHIBITION.**—The oldest horticultural Society in Germany—the Verein zur Beförderung des Gartenbaues in den preussischen Staaten—will celebrate its seventy-fifth anniversary by a grand general exhibition, in which foreigners can partake. The programme and its first supplement include many high prizes, in total 50,000 marks (£2500), and many prizes of honour, amongst which is a very high prize of the Emperor. It would be of the greatest interest, also from the commercial point of view, if English growers would exhibit there, especially Orchids, but also Chinese Primulas and Cyclamen, to see if the English are better than the German. The term for inscriptions expires at the 1st March. Address to the Secretary General, Berlin N., Invalidenstrasse 42.

— **PRUNUS NANA.**—Some plants of this pretty little Prunus are at present in flower in the conservatory at Kew. Although very attractive, whether grown outside (when it flowers in early spring) or forced for greenhouse decoration in winter, this delightful plant is very rarely met with, doubtless on account of its not being better known. It belongs to the dwarf section of the genus, and at Kew when mature forms twiggy bushes 3½ feet in height by the same in diameter. The flowers resemble in colour and shape those of the common Almond, but are only about half the size. They are, however, very freely produced on all parts of the previous year's growth. To succeed well with this plant it is advisable to propagate a few each year, as young plants make better growths and flower more profusely than older ones. It is a native of South Russia, and used to be known as *Amygdalus nana*.—W.

— **LIVERPOOL HORTICULTURAL ASSOCIATION.**—On Saturday evening the annual dinner to members and friends was held, the attendance being quite up to the average. The tables presented a charming appearance with their pleasing decorations, which had been done by members of the Committee. Dinner over, the chair was occupied by W. F. Rogers, Esq., the Hon. Treasurer, who was supported by Messrs. R. W. Ker, J. Kellitt, C.C., J. White (Chairman of the Association), T. Foster (Vice-Chairman), and Mr. W. Dickson (Secretary). The usual loyal toasts were proposed, and heartily responded to by those

present with musical honours. Messrs. R. P. Ker & Sons gave handsomely by providing punch and cigars for all present; and Messrs. T. Davies & Co. presented each person with a box of cigarettes. Votes of thanks to the Chairman, and a splendid musical programme was much enjoyed.—R. P. R.

HINTS ON FORCING.

THE next few weeks are anxious times for those who have to keep up a constant supply of cut flowers and flowering plants. Balls and parties are continually taking place, and these make a largely increased demand for flowers. The bulk of Chrysanthemums are over, so we have to depend almost entirely upon forced flowers for our supply. Camellias may, of course, be had in quantity where they have been gradually induced to flower early by giving them extra heat during the growing season. These, however, are not so favourably regarded for decorative work as formerly, being somewhat too stiff to be used in quantity. Among plants that can be flowered in cool houses in January, Epacris must take high rank, as they supply flowers in beautiful shades of colour, and of the right style to give the necessary touch of lightness to both plant and cut flower arrangements. These are qualities found wanting in many January flowers, and therefore constitute a strong plea for the more extended culture of the Epacris.

Seeing, then, how much we depend upon forced flowers, it is important to avoid, as far as possible, errors in their management, as a mistake usually means a blank in our chain of supply. I propose, therefore, to offer a few remarks about forcing, which I trust will be of service to some. Tulips are, I think, amongst the most easily managed and useful winter and spring flowers we have. They last a long time when cut, and if used with the bulbs attached, and surrounded with damp moss, they are suitable for arranging in an infinite variety of ways, and last quite as long as if left undisturbed in the pots or boxes in which they are grown. For early work I consider there is nothing better than the scarlet *Duc Van Thol*. It can be obtained very cheaply, and the colour is a bright and attractive one, so much needed to brighten up the dreariness of the dull season. Each year I become the more convinced of the importance of potting the bulbs early, so as to secure plenty of active roots before the bulbs are placed in heat. If this is done they will bear very hard forcing with impunity, and throw the flowers well above the foliage.

When Tulips are prepared in this way I am inclined to believe that frequently they do not receive such copious supplies of water as they need after they have been placed in heat about a week. I make a practice of turning a few out of the pots to examine the roots, and I invariably find these are closely packed round the sides of the pot. When such is the case the whole batch is watered several times so as to thoroughly moisten every particle of soil and root. In many instances I have noticed that this copious watering has a wonderful effect upon the progress of the plants, as they seem to grow very quickly; and if kept near the glass the flowers show a substance of petal which forced Tulips often lack. Let the conditions under which this copious watering is advocated be clearly grasped, or the results will be disappointing. These are—that the bulbs must first have plenty of roots, and be grown in a strong heat. *Chrysolora* is a capital yellow variety for early forcing, and *L'Immacula* and *La Candeur* are good whites. I find it is an excellent plan to syringe Tulips freely till the flowers begin to show colour, as it keeps green fly in check, and the young leaves appear to revel in the treatment.

Roman Hyacinths are always of great service, and it is a good plan to make their season as long as possible. The latest bulbs I leave plunged in ashes in the open air till the flowers begin to open. The bulbs do not make roots quite so freely as Tulips, and if they are overwatered the young roots quickly decay, and some of the flower bells turn yellow. When, however, the soil in which they are growing becomes fairly dry copious supplies of water should be given. When the flowers are expanding I find a rather dry position suits them.

Retarded Lily of the Valley crowns are of immense service up till the middle or end of the present month; from that time onward ordinary crowns start freely enough. These should be given a bottom heat of from 80° to 85°, be covered with moss or cocoa-nut fibre refuse, and kept constantly moist. When a bed with bottom heat is not at command good results may be obtained by plunging the pots in boxes placed over the hot-water pipes, and from the middle of February they succeed admirably if placed on shelves or beds without bottom heat.

The value of Daffodils for growing in pots is now largely recognised, and they ought to be grown in quantity by all. Many of them do not force well early in the season, but from the present time they may be brought on gradually in a little heat. The old double yellow variety, the Tenby Daffodil, and Butter and Eggs, are suitable for early forcing. The second named I this season had in flower by the second week in December, every bulb flowering. Close observation has convinced me that it is not sharp forcing alone that sends many of the flowers blind, as it is often brought about by a sudden lowering of the temperature around them when the atmosphere is laden with moisture. By removing pots from a damp to a somewhat dry position I have frequently noticed a marked improvement take place quickly. Sir Watkin, rightly called the King of Daffodils, is so good that it is a pity to risk chance of failure by forcing early, but if taken into an intermediate house about the middle of January it succeeds admirably. The main batch should, however, be allowed to advance in an ordinary greenhouse temperature.—PLANTSMAN.

(To be continued.)

LÆLIO-CATTLEYA ROSALIND.

AT almost every meeting held in the Drill Hall one may see new bigeneric Orchids, chiefly Lælio-Cattleyas, and the majority of those shown possess distinctive features and great merit. Of the several staged during the year 1896 those from Messrs. J. Veitch and Sons, Ltd., Chelsea, have been in the front rank, and that depicted in the engraving (fig. 16) is one of their latest introductions. It was shown at the meeting of the Royal Horticultural Society on December 15th last, and received from the Orchid Committee a first-class certificate. The petals, which are white, are somewhat narrow, but the sepals are broad and fimbriated, with a margin of white round the delicate rose of the central portions. The lip is purplish-crimson, with abundant shadings of blue and a golden-veined throat. The parents were Lælia Domini and Cattleya Trianae.

THE ORCHID HOUSE IN JANUARY.

ONCE again the old year has given place to the new, and as each succeeding week will now see the daylight lengthening, increased activity will soon be noted among our Orchids. One of the first signs of awakening vigour is the appearance of the flower buds at the nodes all along the stems of the deciduous Dendrobies. In small collections it is not usual to see these in flower very early, consequently such as *D. Wardianum*, *D. Devonianum*, *D. crassinode*, *D. primulinum*, and *D. Pierardi*, not to mention more, are just now at this stage. A little more warmth will now be beneficial to these, but let it be applied gradually. Plants rushed on too rapidly never carry so many blossoms or bring them to such perfection as others brought along more steadily and naturally. The fabric of the flowers is thin, evanescent in character, and wanting in the brilliant colour characteristic of this fine genus.

Many of the nodes, too, will push growth bud instead of flowers, the good old *D. nobile* and *D. crassinode* being old offenders in this way. Well ripened plants that finished their growth early should be the first to be placed in heat, later ones being allowed a little more time. The roots should have one good soaking in a pail or tub, and no more water given until they are again quite dry, when the amount must be gradually increased as the blooms develop. They should be kept quiet if possible for a little while after flowering, unless the season is much advanced, as the quicker the growth is made the better. The longest bulbed kinds, as *D. Devonianum* and *D. Pierardi*, seldom start too early, as they require a long season of growth.

The upright growing distichous-leaved set, comprising *Aërides*, *Saccolabiums*, and the like, are usually active at the roots before any signs of new growth appear, and in this they differ from the majority of Orchids. It is easy to see which plants require most water by observation of the roots, but it is better with all in this section to be a little on the dry side with root moisture now. *Saccolabium giganteum* is carrying its beautiful spikes of bloom, and naturally takes more than such as *Vanda coerulea* and others that are at their quietest time. *Phalaenopses* and the smaller growing *Angraecums* must be kept just moist, while the larger members of the latter genus take a good supply of water, their roots being almost as active now as in the growing season.

Cattleya Percivaliana is a beautiful kind now coming on rapidly, some of the earlier flowers being fully expanded, while the swelling sheaths of *C. Trianae*, *C. chocoënsis* and others tell of a rich floral treat in store. With these, as with the Dendrobies, steady progress is best, while the summer blooming *C. Mossiae*, *C. aurea*, *C. Dowiana*, and even *C. Mendeli*, are best kept as quiet as possible, not by drying the roots, but by grouping them at the coolest and driest part of the house. *C. Eldorado* is an erratic species, and looking through the houses to-day I find that many plants of this species are emitting roots freely. If these had been out of condition at the roots I should have repotted them, but they are mostly growing on Tree Fern stems, and quite healthy, so they will not be disturbed.

Repotting, in fact, is almost at a standstill; but very soon there will be plenty to do among the Mexican *Lælias*, autumn and winter flowering *Cypripediums*, *Calanthes*, *Pleiones*, and *Thunias*. It is high time, then, to look over the stock of composts, and get these prepared beforehand. Peat may be knocked up and sifted, the sphagnum moss picked over, and a good stock of clean pots, crocks, and charcoal got ready. Making labels and stakes too will

be useful work during wet or frosty weather, and where the Orchid baskets are made at home these should be prepared in various sizes. These little things make a great difference to the press of work later on, when repotting is in full swing.

The flowering house should be kept fairly warm and rather dry, for it is important that many kinds of Orchids do not get chilled at this season. If there is a scarcity of blossom a few plants of *Poinsettia* may be placed among the Orchids, if these are at command, the bright and telling colour of their bracts helping the somewhat neutral tints of many Orchids. *Iris fimbriata* is another plant that looks well among them, the delicately marked blossoms resembling Orchids considerably. Remove all dead flowers frequently, and change the position of the plants as often as possible, this giving the idea of greater variety. In choosing foliage plants for grouping with Orchids give the preference to fresh Ferns rather than to brightly coloured plants, as *Crotons*, *Coleus*, and the like.

The flower spikes are pushing up in all directions in the cool house, *Odontoglossum crispum*, *O. luteo-purpureum*, *O. Pescatorei*, and all the allied species, hybrids and varieties, showing grandly this season. All these plants must be kept pleasantly moist at the roots, and while not recommending a great advance in temperature the plants are all the better now for comfortable quarters. A little warmth in the pipes allows of free ventilation and frequent damping, and the genial atmosphere thus generated is conducive to the full development of the flower spikes. Where slugs or woodlice are troublesome these must be diligently trapped by the usual methods, and a watch kept on the plants by night, or there is great danger of a whole season's work being ruined by these troublesome pests.—H. R. R.

IN A GLOUCESTERSHIRE APPLE ORCHARD.

CONSEQUENT upon the receipt of an invitation from Charles Bathurst, Esq., J.P., of Lydney Park, conveyed through his agent, Mr. James Lander, to visit Lydney, and there give, in the extensive grass orchard adjoining the park, demonstrations to both tenants and labourers, in standard tree pruning and incidental subjects, I went down to that place on Tuesday the 12th inst. I was met at the station and conveyed to Mr. Lander's residence, where I not only abode, but was favoured with hospitality of the most pleasing kind, such as shows that in that part of the kingdom the stranger within the gates is soon made to realise that he is no longer such, but is an esteemed friend. Nothing could be warmer, heartier, or kindlier than was my reception from everyone.

Early on the morning of the 13th inst. I was taken into the orchard. I found there had been made adequate provision of ladders, steps, saws, knives, and chisels, also several of the estate labourers were at my disposal. We immediately commenced work. I would first say, however, that this one orchard—for there are several others close by—comprises about 8 acres. It has in it Apple trees almost exclusively, only a Pear tree or two being found.

The trees seem to have been of four diverse plantings. There are many veterans, apparently not less than from sixty to eighty years old, having huge stems and large heads of thick, stubby, mossy, cankered wood, such as could not possibly be converted into profitable trees. These I advised be all removed as soon as may be convenient. Then there are many large trees evidently planted about thirty years, all fairly clean in stem and wood, but having heads of close dense growth. Next came many trees, some ten to twelve years planted, all in fairly good condition, and lastly were numerous young standard trees, planted about a year since, and all protected by wooden cradles.

Sending the labourers into the strong young trees, first to clear off the breast wood and remove a few branches, we were enabled to gradually lead up to the tackling of the largest of the second form of tree, and these needed considerable thinning, for the heads were exceedingly dense. A couple of men were sent into the heads jointly, so that I had three or even four trees to direct the pruning of at once. This, however, was easily done with the aid of a long rod. Still further it was evident that the men, although not much accustomed to this form of tree-pruning, especially when taking so drastic a form, soon grasped the matter, and proceeded to perform the work with much intelligence. After two days' tuition I regarded them under Mr. Lander's active oversight, as being capable of thinning the entire orchard satisfactorily.

Beyond removing some branches, which crowded the heads of the old trees, we left these severely alone. They can hardly be too soon thrown and burnt, thus becoming, in the form of potash for manuring, more useful in death than they now are in life. The quantity of branch cut out of several trees seemed to be, as it lay upon the grass, inordinate. The work was not without critics, for Mr. Bathurst had issued such numerous cordial invitations to tenants, farmers, gardeners, and others, to look in during each afternoon, and very many attended. Some of the farmers I overheard rather thought I was having the thinning too severely done. The gardeners, however, to a man, and there were numerous intelligent men amongst them, coincided with my view. I

stated that trees thoroughly thinned looked thin only relatively, because they had previously been so inordinately dense. If the heads now looked thin, they would look thick enough in leaf; also, that relieving the heads of so many branches enabled the roots to support crops of fruit of far superior size and quality, and that the gain eventually would be great.

I gave an exhibition of grease-banding of tree stems to check the winter moth in its effort to climb the trees in the late autumn. The band was made of treble folded brown paper, 9 inches broad, tied round the stem tightly with string about 12 inches from the grass, then daubing it neatly with cart grease. I explained the nature and habits of the winter moth, the time of year it deposits its eggs, its sexuality, and habits, and showed how the grease properly laid on proved to be a

having little or no fibre, and seemed in the lifting to have been carelessly cut with a spade. It was a pity that trees so ruthlessly served should ever be sent out. No wonder, in spite of fair treatment, the trees began to canker, and seemed to be literally stunted and starved.

The bulk of the varieties grown in the orchard and locally are local ones, and many are small and of indifferent quality, even for cider making, apparently the chief use to which Apples are put in the West of England. It need hardly be said that growing for such purposes gets little sympathy from me or from horticulturists generally, who think the Apple has far higher and nobler purposes to serve, as good wholesome food to satisfy the needs of a vast fruit-loving people than to be converted into an intoxicating beverage.

FIG. 16.—LÆLIO-CATTLEYA ROSALIND.

barrier, over which the female insects could not pass, but were caught, and died. This information, which was listened to with deep interest, seemed to be new to many present, and the demonstration was very successful.

Then we had a tree-planting demonstration. A neighbouring farmer, who works his own standards, sent in a few capitally rooted trees about three years grafted, and having plenty of fibre. Holes were opened in the soil, which is of a reddish stone brash, yet apparently excellent for Apples, the bottoms well broken up, some of the soil returned as to bring the bottom up to within 6 or 7 inches of the surface, and the trees were planted. I first went over the roots, cutting out all striking downwards, all jagged or badly placed ones, and paring off the severed ends, then in planting setting them out evenly and thinly. I had some fine clean fresh soil brought to lay about the roots, and afterwards the natural soil was filled in. A few of those young trees planted in the winter of 1895-96 that were evidently doing poorly, were on my advice lifted. These were named, were of good known varieties, and came from a nursery of repute. Yet it was evident the roots had been in lifting shamefully mangled, for they were mere stumps of a few inches long,

It is not possible to deal fully with all that was said and done in this orchard during the two days' demonstration. It was, however, most evident that in inviting tenants and neighbours to look in that Mr. Bathurst wished or hoped, especially seeing how deplorably bad is the general condition of the Apple orchards, that, stimulated by his example at home, they would follow it; and, indeed, there is need they should. If they have no higher claims than now exist it is but too evident that the grand county of Gloucester will never put into the market a single Apple calculated to counteract that tremendous competition the home grower is now experiencing at the hands of the American and Canadian Apple growers.

The situation of the Lydney orchards being a short distance from the Severn, is naturally a humid one. No wonder, therefore, moss and lichens abound on the older trees. I told my auditors that a thorough dasting on a quiet night or morning, when the trees were moist, with fresh-slacked lime, literally smothering the trees, was a most efficacious remedy. I had arranged to give a lecture on "Apple Culture in Orchards," in accordance with the best methods, at the National Schools, on the evening of the 13th inst. In response to the invitation Mr.

Bathurst issued through his agent, Mr. Lander, about fifty persons, all evidently deeply interested in the subject, attended. Mr. Bathurst kindly presided, and after explaining the objects in view, introduced me. My address was a long one, extending over ninety minutes, spoken from notes, but so closely was attention held that none present moved an inch the whole time, except one who had to catch a train, and when I had concluded everyone seemed to have been greatly impressed, and a hearty vote of thanks was accorded.

The lecture covered wide ground, for after referring to the demonstration of the day, I pointed out that the modern idea of Apple culture was in relation to securing a raw fruit supply for the nation, and to that end my remarks would be addressed. I deprecated strongly the practice of planting young trees in the soil of old exhausted Apple orchards as bad practice, but mentioned that Plums would thrive well after Apples, and recommended, to secure a good succession over a long season, to plant Rivers' Early Prolific, Czar, Victoria, Emperor, Monarch, and Archduke, with of Damsons Farleigh Prolific and Bradley's King.

I advised that young Apple trees, whether standard or dwarf, should always be planted in fresh soil in sunny situations, and where practicable on slight ascents rather than in valleys, thus giving the trees more light, air, and warmth, also that the soil be deeply worked by trenching or subsoiling, and if well manured first for a root or Potato crop, then in the late autumn it should be in the best possible condition for planting, and then no raw manure whatever should be used. In relation to the planting of suitable trees I advised the formation of estate nurseries, under competent management, a remark which met with the approval of the Chairman, but who nevertheless naturally wished to see reciprocity in the form of proper after treatment on the part of the tenants. Distances for planting medium and strong growers were given, also instructions as to the planting, staking, and other routine work. I advised, where practicable, if trees be purchased from nurseries, getting maidens as cheaper and less risky. The first and second year's prunings, and later treatment were described, also in case of under cropping on arable soil, the best other bush fruit to plant, culture in general, cleaning, thinning, top-dressing, and feeding with manures, and sewage, especially when the trees are carrying large crops, were all referred to.

The subject of root-pruning and the object in view was mentioned, the special purpose being to convert mere wood-producing buds into fruit buds by checking the too strong flow of sap. The mineral constituents of Apples were described, and it was pointed out that to replace these in the soil the applied manures should consist of about nitrogen 4, potash 6, and phosphate 3, given if artificials at the rate of about 5 to 6 cwt. per acre, or else in small quantities of several ounces to each tree. The various insect pests to which trees are subject were described, and how to check them, especially in relation to the spraying of trees with arsenical mixtures. I advised that Parish or District Councils or landowners might render good service by providing at moderate cost for the use of the locality the needful sprayers, tubs to prepare the mixture, and the materials also, as it was so improbable that any one grower would do anything, especially when his orchard joined on to others that were left unsprayed, and probably smothered with caterpillars. The renovating of sound old trees of worthless sorts by spring grafting was described.

Then the gathering, storing, grading, and marketing the fruit came under notice, especially in relation to checking foreign competition. I urged in the strongest way I could the forsaking of our old bad methods, copying the very best of the foreigners, and in that way getting our fruit into every grocer's store, as the imported fruit does. Naturally, the full exposition of these points took some time. Finally I gave short lists of suitable Apples for general, if not always best for local culture. For eating—Irish Peach, Worcester Pearmain, King of the Pippins, Cox's Orange Pippin, Adams' Pearmain, and Cockle Pippin; of medium growers for standards, as cookers, Manx Codlin, Stirling Castle, Cox's Pomona, Potts' Seedling, Bismarck, and Lane's Prince Albert; then of strong growers for wide distances, Lord Grosvenor, Warner's King, Blenheim Pippin, Waltham Abbey Seedling, Newton Wonder, and Bramley's Seedling. All may not accept these lists, but generally they are of the best.—ALEX. DEAN, F.R.H.S.

[Relative to the experience above described, Mr. Lander writes to us as follows:—"Mr. Bathurst, and all who saw and heard Mr. Dean, have only one opinion, and this is that he is thoroughly master of the subject he dealt with. His lecture was the best I have ever heard, and there are scores of people now regretting they were not present."]

WINTER PRUNING.

(Continued from page 14.)

GRAPE VINES.—On many buildings there are Vines that never produce any fruit. In other cases exactly similar the Vines bear abundant crops. The growths in the first case are let grow anyhow, and are cut back in winter to a couple of eyes, and the result is a splendid crop of leaves. In the other instance the spurs are kept so far apart that each growth has space for the display of its leaves, and pinching is practised at the first joint showing a tendril or bunch, usually the sixth from the base, and the laterals are afterwards kept from overcrowding the main leaves. Such, pruned to two buds as soon as the leaves are down, give

the desired bunches, surplus growths being rubbed off. Nothing is so tractable as the Vine. It wants a south aspect, and a generous soil containing plenty of grit and free drainage. When the rods get old, and the spurs long and weak, training in a young cane and cutting an old rod out makes all right again, only get spurs at the right distance apart (12 to 18 inches).

PEACHES AND NECTARINES.—Though often advised for house walls they are miserable failures, for cottagers and farmers will treat them like Apricot trees, and get sorrowfully small fruit and mere wrecks of trees in a short time after the space is covered. Still, some get along fairly well with such treatment, the trees being given a good thinning in autumn as soon as the fruit is gathered, thus reserving the younger wood, and always having some new ones every year. Under this Morello Cherry-like treatment the trees bear on both spurs and last year's shoots. It has the advantage of being very simple, and it must be said gives fruit when the annual shoot system fails, for the spurs always have the wood riper than the stronger sappy shoots.

The orthodox exclusive, last year's wood-bearing system is almost too much for cottagers and farmers, and it must be said for many professionals, as evidenced in the miserable examples frequently met with on walls. Of course, it is the climate, but it is more the change of methods rather than divergence in weather, for Peaches and Nectarines are quite as well done in some places now as ever they were. The pruning is generally the last done, but why the old wood should not be cut out after the fruit is gathered, as is done under glass, is not so clear. If a good thing for one it ought to be for the other. With fan training the system is easy enough, the thing being to have each year enough sturdy well ripened shoots for supplanting the preceding ones. If a limb goes off, or it is desired to cut out a worn-out branch and supplant it by vigorous bearing wood, the matter is easy, and though the trees so treated may not be equal in appearance to those on the Seymour method they are very serviceable.

On account of the facility in distinguishing the buds, pruning is deferred until they commence swelling in the spring. The weather is also then more favourable to the operator, and if any damage has been done by frost it is clearly seen. But from the advanced state of the buds very little can be done in the way of dressing the trees to prevent the incursion of insects in the coming season. Indeed, little of that sort of thing is now done, whereas formerly it was as common to dress fruit trees in winter as to prune them. Even when the trees were loosened from the wall something was done to keep pests from again appearing to devastate the growths and crops. Walls were dressed as well as the trees, and no doubt did some good. I advise this very desirable practice, for, whatever may be said to the contrary, there are pests that hibernate, red spider being one, and to kill one of these red globules (they coil up so as to resemble an egg) is many hindered existing. Any of the advertised insecticides will do for them, as when trees are dormant the solutions can be applied at a much greater strength than would be safe when the trees are in growth. Aphis eggs are usually deposited on the shoots by the buds, and may be killed by the caustic soda and pearlash wash, but it must be one-fourth weaker than employed on Apple trees, and only employed when the trees are quite dormant. If sprayed on, the wall gets a share, and every pest being wetted there is an end of them. The fungoid pests are hardly gettable, for both blister fungus (*Exoascus deformans*), and fruit rot fungus (*Monilia fructigenum*) have perennial mycelia, and as dormant in the wood as the trees, while mildew is boxed up snugly in the perithecia.

PEARS.—Perhaps the most satisfactory of wall fruits, enormous examples being produced. What has been stated under Apples applies to Pears. It is simply a question of keeping the spurs thin, and having little or no spray, for there is never a satisfactory crop of shoots and fruit at the same time. Extension reached its limit, then comes the struggle; either the spurs must have light without an overgrowth of sappy shoots, or these must be prevented by root-pruning. Sometimes it is better to start boldly afresh, cutting away some or all of the branches and training in others, instead of going on from year to year with barren trees. Even, in certain cases, heading every limb, and regrafting gives excellent results in the case of trees on Pear stocks. Indifferent or bad doing varieties may thus be supplanted by the most approved. Fan-trained trees are readily treated in that way, but horizontal trained ones are less amenable. The thing is to do something, and not go on from year to year with nothing but a crop of shoots. Insects same as Apples.

PLUMS.—Everybody goes in for Plums. There is always a more or less glut of them, and they never bring the price of Apricots. Of course, they will grow on east or west walls, but Apricots want the best southern aspect. That makes things better, as the east can be kept for the Plums, and west for the Pears. Plums are best fan-trained, as the growths can be adjusted to fit in anywhere, and when they become too crowded in the limbs by the spurs these can be thinned. Overgrown or old trees also can be rejuvenated by cutting out old limbs and training in young shoots, which in the year following will form spurs, and in the next bear enormously. If left alone there will be the usual paucity of fruit and a great quantity of useless shoots. Spurring side shoots to an inch of their base, and keeping the spurs fairly thin and close to the wall, is about all Plums require, with shortening leaders to get growths at the right places.

In the matter of insects, what answers for Peaches suits Plums in the way of precautionary measures; but the wood is harder, and will bear more in the way of strength. Aphis and red spider are the worst enemies of Plum trees, the eggs being deposited on the shoots. This as regards aphis, but red spider hibernates—both species of *Tetranychus* and *Bryobia*.—G. ABBEY.

A GARDEN IN THE ISLE OF WIGHT.

[An Address (amplified) by Rev. H. EWBANK to the members of the Horticultural Association at Newport.]

GARDENS differ very much; indeed, there are not two quite alike. You may tell something of the character of a man from seeing his garden, and the way in which its operations are carried on. Now what I object to very strongly is sameness—red Geraniums and yellow Calceolarias weary you—they are no better than a Turkey carpet or a mosaic floor; it is a question of colour with them, and nothing else. Gardening is very different now from what it was twenty or five and twenty years ago, and I think a passage which was written about twenty years ago will explain to you what I mean.

"For some years past," Dr. Wallace says, "the severe style of high art has invaded our gardens, and everything has been sacrificed to the ribbon and pattern border—where diversity of tint, no doubt often very skilfully combined, and regularity of outline have had unlimited sway. Doubtless the effect at first both pleased and surprised, bright and gay combinations delighted the eye; everything was neat and in order. But, alas! as nothing in this world is perfect, so after a time it was found that eternal regularity of colour and outline grew tiresome, and that the scarlet Geraniums, blue Lobelias, and yellow Calceolarias repeated in every garden failed to please," and so the passage goes on at some length, ending in this way.

"After all this system has the following great objections. 1, The eye wearies after a while of the eternal pattern making, and rests with preference on irregular and diffused outlines, as exemplified by Nature's grouping. 2, The majority of plants used for pattern borders are entirely devoid of fragrance, and the sense of smell is not gratified. 3, Under the pattern system for eight months of the year the beds are devoid of beauty, and except such few as are filled in with spring bulbs all is bare and desolate."

This seems to me a very formidable indictment against this kind of gardening, and I for my part take no interest in it; and again, while everybody is free to have his own opinion, and though I fear I am in a hopeless minority, as a rule, I must say I do not care very much for flower shows. There is so much that is very unnatural about them, and they leave out of sight the freshness, the variety, the many-sided look with which all Nature abounds. A few points are fixed upon to the exclusion of everything else, and very often what I should call an utter monstrosity wins the day—e.g., a prize Pansy is a very artificial thing indeed; and I should say an ugly one.

I have before me some of the requisitions taken from a book on florists' flowers which are as follows, "It must be perfectly circular, flat, and have a smooth edge; the petals should be thick and of a rich velvety colour; whatever the colour, the three lower petals should be alike; the two upper should be uniform, and there should be no notched edges, no crumpled petals, &c., &c." I may be quite wrong, and I daresay I am, but I would not grow a flower under such bondage as that, and I dispute its being beautiful altogether; more than that, flowers look so uncomfortable at a show. Wordsworth has said, "Tis my belief that every flower enjoys the air it breathes," but I am certain I have been at exhibitions on a hot summer's day, when the tents were so stuffy that it seemed very probable that we should all be asphyxiated, and the poor flowers looked as if they were crucified.

In nothing of this sort my delight in a garden is found. My aim is the following. I desire first and foremost to have flowers with me all the year round, and never to be without them, excepting in the time of severe frost. From January to December the ceaseless round goes on, and then I think that these flowers become one's friends, and the closest tie is formed. Secondly, we should get to know as much as possible about these plants—e.g., so far as it is compassable to do it; the order and the family to which they severally belong, the affinities and relationships they have, and where each one fits into the great procession of Nature, and the exact place it has. I do not say that I can do this in my garden half so much as I should like to do it, but it is a point to aim at nevertheless, and very especially as connected with a garden (for it is not a studio or laboratory of which I tell) one desires, unless it be about a very common thing indeed, to find out something about the habitats and surroundings of all these flowers, the kind of way in which each one manages to live at home, for this gives the clue more or less to the best method of growing them. Let me only add that we must never servilely copy what we find, for there would be certainly a mistake in doing that. One screw loose, so to say, would throw the whole thing out of gear; but still we must have some general ideas, or no progress can be made at all. It would not do to put a water-loving plant—e.g., a Kämpferi Iris on a rockery, nor an Oncoclycus Iris from the plains of Central Asia, and, therefore, accustomed to drought, in a pond. We must more or less find out what each of our favourites requires, and copy it here in a way, or (which is very often the better plan) give it something which will do instead of that which it has been accustomed to receive.

There is a wonderfully accommodating power in plants, but you must not drive it too far, and should rather follow than force; and I venture to think nothing in the province of a gardener is of more importance than sympathy. If he has it he gets to see into the wishes and the desires of the creatures whom he is tending. Constant use and familiarity give him a sort of second sight, and he can oftentimes treat a plant off-hand to just what it requires. So I should think it is with an experienced doctor, whose power for diagnosis must increase. I was reading an account the other day by Mr. Dolling of his Church work in

Landport, and I came across an assertion with which I am heartily in accord. He says that "flowers sooner than men find out those that love them," and nothing can be truer than that. More even than this, there is often the greatest satisfaction and pleasure in finding out about some very difficult subject—perhaps after repeated failures with it—just what it requires. It comes to you like a shot by some sudden inspiration, sometimes from an accidental cause, and it satisfies you and pleases you in a way which cannot be exaggerated.

I have many plants in my garden which used to give me a great deal of trouble, and now give me no trouble at all. It has all turned on very little points. Some unsuspected cause has been at work, and the wonder is that one never thought before of what is so simple at last. Max Leichtlin showed me the other day at Baden Baden a plant which had bothered him I think for eighteen years, but at last by growing it in close connection with another plant the whole difficulty has been overcome. There is a vastly great difference between these tricks of cultivation with plants and experiments on living animals. No tortures of vivisection are required to find out the secrets which it is desired to lay bare, and if a great mistake has been made—as too often occurs—there are no very dreadful consequences to ensue. If I do lose a plant I hope for better luck next time; the loss is repaired as soon as possible, and I begin again quite complacently. *Mutisia decurrens* is an instance of a plant which used to be very troublesome to me, but has now ceased to be so. Many others might be given.

Let me say that I don't believe all the world over there is a much better little spot for the cultivation of plants than the Isle of Wight, and the north side is better than the south, the reason being that we have better soil, and we are not nearly so much exposed to the ravages of wind as they are in the Undercliff. I should say that about Ryde the advantages for growing plants and shrubs are very great indeed; the soil and the sunshine are in their favour, and the moisture-laden atmosphere, which some of us do not like for ourselves, suits them exactly. It is often wonderful to me to reflect how in my little bit of a flower garden which is about three-quarters of an acre in size, the denizens of so many climes agree to live together, and somehow to a certain extent to lay aside their own peculiarities, and to be willing to do well in my hands. I would name at random the following, which are apparently quite happy under my care. *Rubus arcticus*, from northern regions of course; *Gerbera Jamesoni*, from the Transvaal; *Iris Gatesi*, from Asia Minor; *Campanula Allini*, from the Appennines; *Oxalis braziliensis*, from Brazil; *O. enneaphylla*, from the Falkland Isles; *Sparaxis pulcherrima*, from the Cape; *Rhododendron Aucklandi* and *R. Thompsoni*, from the Himalayas; *Rosa berberidifolia*, from Persia; *Poinciana Gillesi*, from South America; *Ramondia pyrenaica*, from the Pyrenees; *Morisia hypogaea*, from Sardinia; *Cypripedium spectabile*, from North America, &c., &c.

Another thing in a garden such as mine, and on which I lay great store, is to have room for very many mementoes of friendship. We all know what it is to long for the "touch of a vanished hand," and no better reminder can be had than what comes from the cultivation of a flower. It almost seems to speak to you when it comes into blossom, and has many words to say.

I have a Rose, *Souvenir de Malmaison*, which came into my hands about forty-five years ago, and which belonged to my own mother. It is quite as flourishing now as when I first made its acquaintance, and bids fair to live on; and if not of relatives or friends, yet in many cases flowers tell the story of some adventure or journey one has had. I only came across one plant when I was in Palestine that was actually in seed; the month of April is, of course, much too early for that, but I did see one, an *Anemone*, which was not far from Jacob's Well, and I avariciously gathered all the seed I could find, from which I raised several plants, which I had here for many years afterwards. In this sort of way everything is individualised, specialised as far as possible, nothing is taken in the gross. I don't care for great breadths of yellow and red, like the Tulip fields of Haarlem or the seed farms of Erfurt, but I love each member of my multitudinous family, and I try to do the best for it I can.

There is one other thing about which I would say a word, and that is I follow the teaching of Dr. Forbes Watson in preferring single to double flowers, and for this reason, there is very much more of character, and I venture also to think of beauty, about them. I know that this is rank heresy with some people; and the glorious Roses which are exhibited in the summer months seem flatly to contradict what I say, but I hold to it nevertheless about an exhibition Rose. One misses the stamens and pistil which give the real expression to the flower, and there is a sensuousness about the wealth of colour in the one case, I mean in the double flower, which I do not like half so well as the refinement and restrainedness and naturalness of the other, the single one. I consider Dr. Forbes Watson's book on "Flowers and Gardens" to be the most beautiful gardening book I ever came across. I advise anyone who wishes to take the best line about these things to have his mind saturated with the teaching of Dr. Watson, and then he will not go far wrong.

Some double flowers are positively ugly, and many are vulgar in the extreme. A double Snowdrop is very ugly indeed, and nothing, I think, is more vulgar than some double Dahlias of renown. It is true that double flowers hold on better in water and last a longer time than the others, and for this reason, and this only as a rule, I have anything to do with them. And now I see that I must not waste any more time with the preface, and I shall proceed to offer you a few selected illustrations, or typical examples they may be called, of the preceding

remarks. I will try very briefly to describe how the dance of the year goes on. As a rule yellow is the colour which predominates most of all at the beginning of the year—Primroses, Celandines, Cowslips, Narcissi, and other things are in evidence of what I say; and as in the woods so it is in the garden as well. Very soon deeper colours and greater brightness are to be seen, and it progresses, till at midsummer the whole place is aglow with Roses, Gladioli, Irises, and other things, and in autumn Tritomas, and single Dahlias and Asters abound.

(To be continued.)

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

As is customary, Simpson's Hotel was chosen for the holding of the annual general meeting of this excellent Society on Thursday, 14th inst. Mr. Harry J. Veitch, the energetic Treasurer of the Institution, occupied the chair, and as the clock struck 3 commenced business by calling on the Secretary, Mr. G. J. Ingram, to read the minutes of previous meetings, which were quickly confirmed by the members present. Amongst the company were noticed Dr. Maxwell T. Masters, and Messrs. J. Fraser, A. Outram, J. Hudson, H. B. May, J. H. Veitch, G. Wythes, G. Dixon, G. Munro, White (Secretary Worcester Auxiliary), and many others. After this preliminary business was concluded, the Secretary read the report of the Committee and the balance-sheet for the past year, both of which were adopted. It is a matter for congratulation to see how admirably the Society is worked, and to know the amount of good that is being done. Though the institution is adding more pensioners to its list this year than has been done on any previous occasion, we are quite of the opinion that the Committee is fully justified in its action, for the Society was never more popular than it is at the present moment—a popularity that it is hoped will be proved in a practical manner by largely increased subscriptions. With Mr. Veitch's able scheme we deal on page 45.

REPORT OF THE COMMITTEE FOR 1896.

The Committee have the greatest possible satisfaction in submitting their annual report for the year 1896, and in doing so they would express their sincere thankfulness that they are able to again congratulate the subscribers and friends of the Gardeners' Royal Benevolent Institution on its continued prosperity and ever-increasing usefulness to those in adverse circumstances for whose benefit it was established.

It is with much pleasure the Committee have to report that the annual festival dinner held in May last was one of the most successful in the history of the Institution, and they take this opportunity of acknowledging their great indebtedness to the Right Hon. the Earl of Lathom, G.C.B., who so kindly presided on that occasion, and whose earnest appeal on behalf of the funds of the Charity elicited such a generous and substantial response. The Committee desire also to offer their most sincere thanks to those gentlemen who so kindly acted as Stewards, and to all friends who in any way rendered assistance in contributing to the success of the anniversary.

In the past year eighteen pensioners have passed away, four of them leaving widows, three of whom, whose cases having been investigated and found to be deserving and eligible, have been placed on the pension list at £16 per annum in succession to their late husbands, in accordance with Rule III., 13. The names of two pensioners have been removed from the list, their circumstances having altered, whereby they are no longer eligible to receive aid from the funds. The Committee are glad to announce that they have decided to recommend an increase of twenty pensioners to the number at present on the books, ten of whom, having been accepted in conformity with Rule III., 5, they ask the subscribers to place on the funds without election. The remaining ten will be elected by the votes of the subscribers in the usual way, making a total number of 161 pensioners on the fund. It is a great pleasure to the Committee to feel justified in thus increasing their liabilities, and to recommend to be placed on the pension list the largest number of candidates ever admitted at any one election since the establishment of the Institution; whilst at the same time they regret that with liabilities, which it is impossible for them to accurately estimate, they are unable to render assistance to a greater number of those applicants who are appealing for aid.

It is gratifying to the Committee to be able to report the formation of a new branch of the Institution at Exeter, which was inaugurated after a most successful meeting held at that place, presided over by the Mayor of Exeter and addressed by the Treasurer and the Secretary of the Institution, and the Committee would express their hearty thanks to the promoters of the meeting, and especially to the Hon. Treasurer and Secretary, for their assiduity and energy, which went far to insure its success. They would also present their grateful thanks to the Hon. Treasurers and Secretaries of the Worcester, the Bristol and Bath, the Wolverhampton, and the Birmingham Auxiliaries for their services and ungrudging labours in advancing the cause.

In the past year a meeting was held at York, presided over by the Lord Mayor of that city, in furtherance of the objects of the Institution, and from the success which attended it the Committee believe that a greater interest will be taken in the Charity in that part of the country.

There have been also held a floral service at York Minster, a floral and fruit stall in connection with a floral exhibition at Exeter, presided over by county ladies, garden fêtes at Osberton and Reigate, fruit show at Reading, and concerts at Altrincham on behalf of the

funds, to the organisers of which, and to the other friends in various parts of the country who have assisted the Institution in any way, the Committee would tender their very hearty thanks.

In drawing attention to the fact that the present year will witness an event which is unparalleled in the annals of this country—viz., the completion of the sixtieth year of our beloved Queen's beneficent reign—the Committee beg to announce that they have determined to endeavour to commemorate so unique an occurrence by establishing a special fund, to be called "The Victorian Era Fund," the interest of which shall be devoted to the temporary assistance of those applicants who are waiting to be placed on the pension list, and who have been subscribers to the Institution. This proposal has already met with hearty and unqualified approval from His Grace the Duke of Westminster (President), Baron Schröder (Vice-President), C. Czarnikow, Esq. (Vice-President), N. Sherwood, Esq. (Trustee), Harry J. Veitch, Esq. (Treasurer), to whom the Committee are indebted for the proposal, and many other friends of the Institution, who have also promised generous contributions towards this object. The Committee would point out that Her Majesty has been the Patroness of the Charity for forty-five years, and only last year evinced her continued interest in its welfare by contributing £25 to its funds, and they believe that in attempting to celebrate the Diamond Jubilee of Queen Victoria in such a manner and with the purpose in view they will receive the support and practical sympathy of all friends of the Institution, as well as of those who take an interest in gardening and flowers. The Committee have also resolved, in honour of the event, to send on June 21st next the sum of £5 to each unsuccessful candidate at the present election whose name is then on the applicants' list.

It is with feelings of deep regret that the Committee have to record the decease of their valued colleague and friend, Mr. James Webber. From the year 1844 his family had been warm supporters of the Institution, whilst for the past twenty-one years he himself had been a member of the Committee, and had invariably done his utmost to promote the interests and further the objects of the Institution, and his loss will be severely felt and his services greatly missed.

The Committee, in conclusion, have the privilege and the pleasure of announcing that the Rt. Hon. Lord Rothschild has very kindly undertaken to preside at the fifty-eighth anniversary festival dinner on Thursday, May 26th, 1897, at the Whitehall Rooms of the Hotel Métropole, and they confidently appeal to all those who are interested in the welfare of the Charity to do their utmost to make the anniversary a marked success. The Committee earnestly hope that the thankfulness expressed for the success attained in the past will be an incentive to further exertions, so that the good work which has been carried on by the Institution for fifty-eight years may continue to grow and prosper.

Auditors.

After the balance sheet had been read the election of officers for the ensuing year was proceeded with, and it is needless to add the proposal that Mr. H. J. Veitch be re-elected Treasurer was received with acclamation. This was also the case with respect to a similar proposal regarding Mr. G. J. Ingram. Each gentleman briefly responded. The other officers, including the Auditors and the Arbitrators, remain as before.

ELECTION OF PENSIONERS.

Owing to the immense number of votes polled on this occasion—nearly 70,000—the scrutineers had an arduous duty to perform, and it was not until about half-past five that the result of the poll was declared. Mr. G. Munro read the declaration, showing that the new pensioners of the Institution and the number of votes gained were:—Joseph Monk, 3957; Charles Smith, 3762; William Milne, 3651; Edmund Papworth, 3395; David Davis, 3307; George Ashby, 3255; William Lee, 3190; Eliza Webb, 3107; Thomas Simms, 2930; and Rachel Jefferson, 2802. Immediately Mr. Munro had read the results a second time Mr. Ollerhead, gardener to Sir Henry Peek, Bart., Wimbledon House, tendered his thanks to all who had assisted in electing Mr. Milne as a pensioner of the Institution, and Mr. Ollerhead showed his gratitude by giving a donation of £20. Votes of thanks to the Scrutineers and to the Chairman for presiding brought the annual meeting to a close.

LARK PUDDING DINNER.

About seventy members and friends of the Institution gathered at Simpson's, at 6 P.M., for a friendly supper. The chair was taken by H. E. Milner, Esq., who was supported by Messrs. H. J. Veitch, N. N. Sherwood, H. B. May, H. Cutbush, J. Laing, A. Barron, J. Hudson, G. Wythes, A. Outram, Owen Thomas, G. Munro, J. H. Veitch, J. G. Veitch, &c., &c. After supper, or lark pudding dinner, as the function is popularly termed, Mr. Milner gave the usual loyal toasts. In a few well-chosen words the Chairman proposed "Success to the Gardeners' Royal Benevolent Institution." He showed how membership eventually entitled the subscriber to the benefits of the Institution if he needed such, and he advised all gardeners to endeavour to subscribe 1 guinea per year. The Chairman also alluded to the "Victorian Era Fund" as an admirable idea for celebrating the sixtieth year of Her Majesty's reign, and added, that should the needed £5000 be forthcoming—and of this he had little doubt—it should form an additional attraction to gardeners, as, by it, all waiting to be elected as pensioners would be entitled to relief according to the number of years they had been members. The Chairman's speech was applauded, and the toast duly honoured.

Mr. Harry J. Veitch, in responding, expressed the pleasure they felt in having Mr. Milner as Chairman. He eulogised the services rendered to the Institution by the late Mr. J. Webber during his twenty-one years' connection with it as Committeeman. As Treasurer of the Institution he was sorry they could not put on more pensioners, but he was pleased that in no year had they put on so many as in the present, while to all unsuccessful candidates £5 would be given, as in the Jubilee year. He drew the attention of the meeting to the number of unsigned voting papers sent in, and said that at the election just held no less than eighty-two papers, containing 890 votes, had to be cancelled from this cause. Mr. H. J. Veitch then propounded his scheme for celebrating the sixty years' reign; this to be devoted to relieving those who were unsuccessful in becoming elected as pensioners. They needed a sum of £5000 for investment, and the interest from this would be divided annually according to the number of applicants, and in proportion to the length of membership of each individual. Not more than £1 per annum per year of membership would be given, so that no one would receive more than £14 in one year without becoming a pensioner, which he could do as a matter of course after fifteen years' membership. The Victorian Era Fund would help those who had been provident. Mr. Veitch instanced a case of husband and wife who, between them, had received £584 from the Institution, and yet had never paid a penny into its exchequer. The subscription list was then read showing promises of over £1500, and Mr. Veitch remarked that a circular letter would be sent to the principal gardeners and nurserymen throughout the kingdom asking for help in furtherance of the scheme. Mr. Veitch was warmly applauded.

Mr. H. B. May proposed the "Health of the Committee," and this toast was responded to by Mr. S. M. Segar and Mr. J. Hudson, the latter remarking that gardeners as a body did not help the Institution as they should. The task of proposing "The Honorary Secretaries of Auxiliaries and Country Friends" was in the hands of Mr. G. Munro. He considered the establishment of auxiliaries was a great success; there were now five of these, and the income from them amounted to £400. Mr. White of the Worcester Auxiliary had sent £165 in 1896, and already had handed in a cheque for 25 guineas as the result of his 1897 work. Mr. White was well received and suitably responded. Mr. Drewitt spoke on behalf of country friends.

Mr. N. N. Sherwood gave the "Health of the Chairman," and expressed the pleasure they had in being presided over by one of the ablest gardeners of the day. Mr. Sherwood also wished success to the Victorian Era Fund. The toast was received with musical honours, and Mr. Milner having responded the proceedings were brought to a conclusion. During the evening songs and instrumental music were rendered by Mr. H. Turner, Mr. Munro, jun., Mr. J. White, and other friends.

GASTROLOBIMUM VILLOSUM.

THIS is a very pretty shrubby plant, and one that should be more generally grown for the embellishment of greenhouses and conservatories. As will be seen by the illustration (fig. 17), the flowers are on small racemes, which are freely produced during the spring and early summer. The standard, or upper portion of the flower, is large and of a dark orange colour, while the wings and keel are claret coloured. The leaves are dark green, terminating in small hooked spines. The stems and leaf margins are thickly set with hairs, from which character the specific name is derived. The species under notice, as indeed do all the *Gastrolobiums*, require similar treatment to that generally accorded greenhouse hardwooded plants. A compost of

FIG. 17.—GASTROLOBIMUM VILLOSUM.

fibry loam, peat, and sand will suit it admirably, and rather firm potting is essential. Efficient drainage must also be provided, and careful watering is of the greatest importance.

AUSTRALIAN FORESTS.—The forests of Western Australia are exceedingly rich in trees of economic importance, among which the Jarrah, or *Eucalyptus marginata*, is now the most important. In constructive work, where wood is brought into contact with soil and water, this timber is superior to that of any other wood in that forest. A healthy tree of average size is from 90 to 100 feet high and from 2½ to 3½ feet in diameter at the base, and it will grow so as to produce logs 2 feet through at the base in about fifty years. It grows in sections where the rainfall ranges from 35 to 40 inches in the year, and the wood when dried weighs 60 lbs. a cubic foot. It is red in colour, takes a good polish, is easily worked, and is good for piles, bridges, boats, furniture, railway sleepers, and charcoal. It is usually found mixed with or near the Karri, or *Eucalyptus diversicolor*, a giant species, straight and regular in growth, umbrageous in appearance, good specimens being 200 feet high, 4 feet in diameter breast-high, and with a stretch of 120 to 150 feet from the ground to the first branch. It is a rapid grower, and will produce marketable timber in from thirty to forty years. This wood is red in colour, very much resembling that of the Jarrah. Its texture is hard and heavy, and it is tough and not easily dressed. For bridge planking, flooring, and beams it is unequalled by any wood in the colony. Karri timber is exported to London for paving the streets, since its surface is not easily rendered slippery.—("Times.")

HAIRY CHRYSANTHEMUMS.

IN spite of the number of varieties that have been raised and distributed since the advent of Mrs. Alpheus Hardy six years ago, how few of them are appreciated. During a lengthened tour of all the best shows this season I seldom saw more than one variety—Hairy Wonder. This was sent out in 1894, and is far and away the best of the whole section. Not only are the blooms of full size, but the florets incurve regularly, and the hirsute appendage to each is fully developed. The colour (deep fawn) is pleasing. No difficulty is encountered in obtaining really fine exhibition blooms, by allowing the plants to make their natural break in April, afterwards securing the crown bud. This is a variety that does not require much feeding.

It is now two years since I saw a really good bloom of Mrs. A. Hardy. Mrs. W. J. Godfrey, owing to the easier growth, has taken the place of the original variety. This, however, does not appear to meet with much favour; seldom can a good bloom be met with. The florets in this are broader than in any other of the section, which now numbers twenty-two, according to the Jubilee edition of the N.C.S. catalogue. Considering the number a poor representation is the actual result. The novelty of cultivating hairy Chrysanthemums has evidently worn off.—E. MOLYNEUX.

CHRYSANTHEMUM NOTES.

"T. G.'s" heading, "A Few Scrappy Chrysanthemum Notes" (page 30), appears characteristic of his writings, for they furnish as interesting reading as anything that has appeared in the Chrysanthemum columns for some time, both from a humorous and practical point of view. I am sure many beside myself feel indebted to your correspondent for his outspoken remarks and the information given respecting the newer varieties and their suitability for market work or as decorative plants for private use.

"T. G., Devon," evidently is no amateur in catering for the markets, nor restricted in the indulgence of the element of novelty, otherwise he could not have given such competent advice so readily for the benefit of those readers who are anxious for knowledge but without the means of obtaining it; at any rate, so closely on the introduction of the newer varieties. The exhaustive selection which he furnishes, and which is supplemented in the Editor's footnote, renders it unnecessary to act on the suggestion which he gives in relation to Mr. Molyneux and his annual selection so far as affecting the number of varieties given for the purpose of late flowering, but we may wish to shout to him "Go on" in the cultural aspect of the case.

There is no doubt a good deal of truth in the statements of "T. G." as regards the craze for size, but I would ask him not to be too severe on the general grower, who may be fired with ambition for prize winning, because they have their dictates in the Judges who award the prizes and the specialists who place them before the notice of their patrons in their annual catalogues. The man who can produce size with quality and evenness of blooms on his stand obtains a better chance than his fellow competitor who has quality without evenness in his products, and as the aim of the exhibitor is to win he may be pardoned for following up the craze for size.

There is little doubt but that "those exhibition chaps" have often a poor or undervalued regard for the decorative class of Chrysanthemums, but at the same time there are some employers who are quite satisfied if their gardeners can furnish a good display of the large specimen blooms in the autumn or win a good share of the prizes at the exhibitions selected for competition.

I am pleased to know I have been the medium for gaining a reprieve for L. Canning without a lengthy petition, and inducing "T. G." to try the plants a second year. If his experience compare with mine I think he will be satisfied with the results. There was scarcely a comparison between the yearling plants and those grown the second year in my case. Is not Jeanette Sheeham a pale yellow sport from L. Canning? I shall add Elmer D. Smith to my collection, and no doubt others will do so on the recommendation of "T. G.," for it is a colour greatly needed at Christmas.—W. S. Wilts.

THE YOUNG GARDENERS' DOMAIN.

TOOL-HOUSE AND TOOLS.

WHEN we think of January and the garden together we are apt to fly to the conclusion that very little can be done then; but when we come to consider all that may be done in connection with all that wants doing to prepare for the superabundance of spring work, which will become urgent with the first break in the weather, we remember that the first month in the year will not be a bit too soon to prepare for the eleven which are to follow it.

A job which may most usefully occupy the leisure of winter is to set the tool-house in order, putting up new shelves, hooks, and nails wherever they are wanted, and finding a good and appropriate place for every tool and garden appliance. It is a good time, too, for getting all

the tools set in order, while those that require repairing can best be spared. May I tender thanks for the space allocated to the "Young Gardeners' Domain?" No one more sincerely trusts that it may inspire further energy in our ranks than—NEMO.

MICE AND CINERARIAS.

THIS being my first attempt to write to any of the gardening papers I fear I shall not be able to wield my pen so easily and fluently as some of our indefatigable subscribers. Having charge of the glass department on a medium-sized garden in Surrey I think I know a little about some of the thousand and one difficulties that the young men of the gardeners' domain have to contend with. I should like to mention one now—viz., mice and Cinerarias. We have here a nice batch of plants, averaging from 8 inches to 18 inches high, and about the same distance through. Having placed them in frames in a cold Peach house to guard against frost, the mice have attacked them seriously, eating some of the plants right down to the soil. Two well-known remedies, and almost a sure and certain doom for mice, are steel traps with grease, and figure-of-4 traps with cheese. But these have been a complete failure in this case, so we have had to resort to poisoning, which has answered fairly well; but still they come. I should like to hear if any brother in the craft has been pestered with mice this season, and, if so, how he got rid of them.—ANXIOUS G. H.

[It seems if mice have their drawbacks that they also have their uses—in stimulating the victim to "wield the pen."]

POINSETTIAS.

WHEN well grown the Poinsettia is one of the finest and most taking plants we have. Its brilliant scarlet bracts are very telling, either in the drawing room or arranged amongst other plants in the greenhouse.

The plants, having finished flowering and been rested, should be taken to a stove temperature, afforded a good watering, and be kept nicely moist by the syringe. Thus treated they will soon break into growth. About the end of March, the growths being 3 or 4 inches long, should be taken off with a slip of the old wood attached. These should be inserted in 3-inch pots, using a sandy compost. Plunged in a strong bottom heat they will soon root. When well struck they must be stood on a shelf close to the glass. The temperature of the house should be about 70° by night.

As soon as the pots are well filled with roots transfer to 5-inch pots in a compost consisting of loam, leaf mould, sand, and a little decayed manure. Be very careful in watering, both now and all through the season, as they soon lose their bottom leaves if too much is given. If this occur they become the reverse of pleasing, being unsightly objects indeed. Continue to grow in a stove temperature. Shade from sun; the leaves are now very tender, and soon scorch. Early in July they should be ready for their final shift. Use 7-inch pots. The compost advised above will do, with a little more manure added. In about a month lower the temperature to 60°; 65° by night. Continue to harden them by the gradual admission of more air, less shade, and syringing until they can bear the house fully open day and night, and no shade.

During the growing season an occasional application of some proved fertiliser is very beneficial. Grown thus they will be sturdy plants, with large deep green leaves down to the pots. When the bracts appear remove the plants to a temperature of 60° by night until fully expanded, when they may be kept cooler, and the bracts will last in perfection a long time. If it is required the old plants may be grown as advised above, but be later in starting them into growth.—SEMPER.

EARLY FORCING — PEACHES AND NECTARINES.

(Concluded from page 38.)

THE thinning of the Peaches and Nectarines may be proceeded with as soon as the fruits have commenced swelling freely. They should be thinned out at intervals of a few days, and the sooner this operation is completed the better it will be for the remaining fruit, as when allowed to remain too crowded the trees are liable to become exhausted. The average crop of Peaches is about one to every square foot, but if the trees are over-robust a heavier crop may be taken from them in order to keep the trees in a good fruit-bearing state. Always keep a sharp look-out for insects. The aphid or green fly will in a few days, if neglected, spread at an alarming rate, and so cripple the shoots that they are a long time making any headway. If these pests are dealt with promptly when first seen a puff of tobacco dust will generally settle accounts for them, but if they appear in different parts of the house it is the best to fumigate.

Red spider and thrips are very destructive pests to the Peach. They may be got rid of by syringing with the XL All liquid insecticide, but if the trees are well syringed with clear rain water these troublesome pests are kept at bay.

The greatest possible care must at all times be exercised with regard to ventilation. Air should be admitted gradually, commencing in the early morning with the top ventilators. We must be guided entirely by the external atmosphere, which if cold will soon give a check to the growth if admitted too freely. To guard against this the temperature may be allowed to get higher than usual rather than admit the cold air in too great a quantity. Close early, before the sun leaves the house.

During bright weather the paths and borders should be sprinkled with tepid water occasionally during the day. Any young shoots that seem to be growing over-robust may be stopped to direct the sap into

more legitimate courses, and to sustain the full capacity of the principal leaves; this should be proceeded with so long as the trees remain growing, the leaders given one bud each time, but the laterals are stopped at the first leaf, where all growth afterwards is removed.

When the fruit begins ripening a little air is left on at night, gradually increasing it until we have the full amount on night and day; this will prove beneficial to the flavour of the fruit. It must always be remembered that three essentials to flavour in Peaches are sun, light, and air. When the fruit commences to colour we must be careful to get it all exposed to the sun, and should any leaves be shading it they must either be tied back or half of the leaf removed.

The ripening of the wood must be attended to thoroughly, as next year's crop will depend entirely on it. Always water the borders with water the same temperature as the house, and at no time should they be allowed to get dry, or a dropping of the buds will be the result. For early work Alexander and Waterloo will give satisfaction for Peaches, and Lord Napier will be found one of the most serviceable of Nectarines. —J. F. DONOGHUE.

THE BLACK CURRANT.

Now that we have such a chance as "The Young Gardeners' Domain" affords, I think it will be a source of improvement if we avail ourselves of the opportunity. For my first attempt I am going to write a little about Black Currant culture.

This useful bush fruit seems to thrive best on a fairly strong soil, deeply worked and well drained, with a good quantity of potash in it. When the bushes show signs of weakness, a good mulching with farm-yard manure early in spring will help them on. If we wish to grow the Black Currant on a very strong soil, it will be a great advantage to burn a portion, and mix a little sand with it; the burning will afford potash. It is not worth while attempting to grow Black Currants on light sandy soil without a good dressing of clay. Cuttings should be taken as soon as the leaves fall. One form of cutting is to take a young shoot, cut off a portion of the top, leaving it about 1 foot long; rub off all buds except three at the top, then insert the cuttings deeply in worked ground in rows 1 foot apart, and 6 inches asunder in the lines, leaving about 4 inches between the buds and the ground. In spring we shall have three shoots from the buds, and roots where the buds were taken off under ground.

Should the growth not be as robust as we like, a sprinkling of sulphate of ammonia will be helpful to them. In autumn these three shoots should be cut back to an outside bud, leaving about four plump buds on each stem. The following spring we shall have six long shoots from the top buds, and six small shoots from the lower buds; in the autumn the small shoots should be cut back to about half an inch of the stem, and the long shoots to about four buds. Continue cutting after this manner until the tree is the desired size. Pruning and transplanting should be done in autumn, and always cut close to a bud. Sometimes when a snag is left, frost and rain will cause the first bud to die.

A second form of cutting is to take a young shoot 1 foot long when the top is cut off, leave on all the buds, insert in deeply worked ground, leaving about 6 inches above the surface. With this kind we shall get strong shoots from above and below ground as well, but not quite so many roots. The shoots from beneath are called suckers. Pruning, manuring, and all else are the same as the other form. This is more productive, but most gardeners like the tree form best; it is better to keep in order, and the fruit does not get so dirty with rains dashing up the soil. —KNEDLINGTON.

[Penmanship good and composition fair, the chief faults being abbreviations of certain words, and omitting the article "the." The lines were too close by half, but written prior to the publication of our advice last week.]

WINTER TOMATOES.

WHAT vegetable is more appreciated than the Tomato during the winter months? and if properly treated fruits can be easily obtained all the year round. The system of growing them here, and one that seems to suit them for winter fruiting, is to sow the seed at the end of March in small pans filled with a light compost. After the soil has been well soaked we sow thinly, just covering the seeds. The pans are covered with a piece of glass and placed in a temperature of 65°. As soon as the seedlings appear the glass is removed and the pans placed on a shelf close to the roof that the plants may obtain the full light, otherwise they will become drawn and weak.

As soon as large enough they are potted in small 60's and placed back again in the same temperature. They require a little shading till they become well rooted, when they are removed to the frames and kept close for a day or two, then gradually admitting more air till they become hardened. They soon require repotting, and are then shifted into 6-inch pots, using a stronger compost of two parts loam with one part spent Mushroom droppings and a little leaf soil. At this period they require careful watering till they become well established, as owing to the large shift the soil is liable to become sodden, which soon checks the plants.

By the beginning of June they are ready for well washed 10 and 12-inch pots for fruiting. These are carefully crocked, as the drainage is one of the most important features. A good layer of rough fibry turf is placed over the crocks, and good strong soil is used, consisting of three parts loam to one of spent Mushroom bed refuse, with a little leaf soil and a good sprinkling of bonemeal. It is rammed firmly, filling the pots two-thirds full to allow a top-dressing later.

After potting they are placed outside at the foot of a wall facing south, to which they are trained, taking them up on the single stem system, and removing all side shoots. When well rooted they are top-dressed with much the same compost as used for potting, only having a little more artificial manure added, and after being top-dressed the pots are covered with half-rotten manure for the double purpose of protecting from the hot sun and retaining moisture. By keeping the side shoots removed they soon have fine trusses of fruit all up the stems. After the fruits have begun swelling the plants are fed two or three times a week. They are grown in this way till September, and then removed to a lean-to house facing south, where they are tied to wires 1 foot from the glass.

The house is thrown open on all favourable occasions, and kept dry, maintaining a night temperature of 50°. The fruits then commence to ripen, and we have always a good supply through the winter; with November a night temperature of 55° to 60° is kept. The variety is Osberton Scarlet, which seems equally well adapted for winter and summer. —A. C. W., Osberton Gardens.

FRUIT FORCING.

Cherry House.—A house of Cherry trees planted out or in pots is found here and there throughout the country, and the fruits they bear are very desirable additions to the dessert at the end of April and through May when the house be started at the new year. The utmost care must now be taken to have the trees perfectly free from aphides, which seem to emerge from the eggs simultaneously with the buds casting their scales, and they at once fasten on the growths. This they must be prevented doing by fumigating with some approved preparation of tobacco, so as to thoroughly annihilate the pests, for it is essential to a good set that the blossom be perfectly developed; therefore effect the destruction of the pests before the flowers unfold. Syringe the trees occasionally up to the blossom showing the loveliest of all white, but cease then, damping the paths and borders instead, and ventilating freely. Keep the house at 40° by night, 45° to 50° by day by artificial means, ventilating at 50°, and allowing a rise of 10° to 15° from sun heat, with full ventilation, closing the house for the day at 50°. Take care not to allow the border to become dry and remain in that state, but water as necessary, so as to keep the soil moist, yet not supplying it excessively so as to make the border sodden, and attend regularly to the needs of trees in pots.

Cucumbers.—Young plants must be shifted into larger pots as they require more root-room, keeping near the glass, putting a stick to those required for trelliswork. The soil should consist of medium textured fibrous loam, with a fifth of thoroughly reduced manure, and adding a little charcoal to keep the compost open and sweet. If a sprinkling of air-slaked lime and soot in equal parts be admixed with the soil it will be advantageous. Plants for frames can be stopped at the second rough leaf. The bottom heat should be 85°, top heat 70° to 75° by artificial means, falling 5° at night and advancing 10° to 15° from sun heat.

Winter-fruiting plants will need top-dressings occasionally, to keep them fruitful, and any that exhibit signs of exhaustion will be the better of fresh supplies in place of as much of the surface soil as can be removed without injury to the roots, using turfy loam, with a fourth well-decayed manure, a pint of soot, and a quart of wood ashes to each bushel. Such surface dressing provokes the emission of fresh roots, and when these are plentiful the plants can be invigorated by top-dressings of fertilisers washed-in or copious supplies of liquid manure. Keep the growths tied to the trellis, cut out exhausted growths, and train-in young shoots so as to maintain a succession of bearing wood, and consequently of fruit. Give each growth space for development, all the foliage full exposure to light, and above all avoid overcropping.

Figs.—*Earliest Forced Trees in Pots.*—The trees of such varieties as Early Violet, St. John's, Pingo de Mel, and Brown Turkey, started in November or at the beginning of December to afford ripe fruit at the close of April and in May, are forming fresh roots abundantly, therefore the bottom heat should be kept steady at 70° to 75°, bringing the fermenting material up to the rims of the pots, and instead of letting them extend over the rims into the fermenting material, place pieces of turf about 2 inches thick round the rims of the pots, and extending over or down the sides, which will keep the roots near and induce a sturdy growth, and the roots can be fed in the turf. To encourage active feeders from the collar fill the hollows formed by the turves with sweet lumpy manure or rough pieces of turf, and sprinkle these occasionally with a little approved fertiliser.

Keep a good but not excessive moisture in the atmosphere by syringing twice a day and damping as required in dry weather, taking advantage of every gleam of sunshine for raising the temperature to 80° or 85°; but admit a little air at 70°, increasing it with the temperature, closing at 75°, and so as to raise the heat to 80°, 85°, or even 90°. Let there be no lack of water at the roots, and with the drainage good

there is little danger of giving too much, many crops being lost by keeping the roots too dry or supplying water too late and irregularly. In dull weather the temperature should be kept at 65° by day and 60° at night, but 5° more in mild weather in both cases. Superfluous growths should be rubbed off, and the shoots stopped at about the fifth or sixth leaf; but trees making sturdy growth will not need stopping, and the finest Figs are borne on extensions. Yet stopping is necessary, especially growth likely to interfere with an equal distribution of the sap and the admission of light and air to all parts of the tree in equal share.

Early Forced Planted-out Trees.—The trees started early in the month and planted in inside borders of limited extent will, the borders having been repeatedly watered so as to bring the soil into a thoroughly moist state, be starting into growth, and may have the night temperature raised to 55°, and 60° to 65° by day from fire heat, with an advance from sun heat to 70° or 75°, but with moderate ventilation. Syringe the trees in the morning and early afternoon of fine days, the latter always sufficiently early to allow the trees to become fairly dry before night, and in dull weather omit the afternoon syringing. Weakly trees may have a good soaking of liquid manure at a temperature about the mean of the house, but it must not be too strong. This will induce the formation of roots, and active feeders being pushed from the collar and surface roots they should be encouraged by light mulching of lumpy material to spread outwards, and then the trees can be nourished to any extent by top-dressing of fertilisers or applications of liquid manure.

Melons.—Seeds sown early in the month have progressed so that the plants are in second leaf, and root action now proceeds rapidly; therefore attend to earthing, and when the small pots are occupied with roots shift the plants into 5-inch pots, always watering in advance of shifting, so that the roots are all preserved in turning out the plants, and not allowing them to become root-bound. Plunge in bottom heat near the glass, a temperature of about 80° sufficing at the roots; 65° at night, and 70° to 75° in the daytime artificially of top heat, with 10° to 15° rise from sun heat being suitable. Place a small stick to each plant for its support until it is large enough to transfer to a hillock in the Melon house, rubbing off the laterals as they appear up to the height of the lowest wire of the trellis. Plants intended for planting out in pits and frames, and trained over the surfacing of the beds, can be planted out as soon as they require more root room, or be shifted into larger pots, stopping them at the second rough leaf.

Soil for Melons.—Heavy loam is preferable to light, and that cut and stacked with about five per cent. of quicklime will have the herbage and its contained pests destroyed. The top 3 inches of a pasture grazed by sheep is most suitable, and this chopped up moderately small will grow grand fruit. An admixture of old mortar rubbish, say a sixth, supplies lime and grit, and the plants grow sturdier for a supply, which is often deficient in turfy loam, and quart of soot and two quarts of wood ashes to two bushels of loam makes the poorest soils suitable for Melons, whilst rendering it hateful to wireworms and slugs. Unless very poor soil or ordinary garden soil is used manure is not necessary; but it is a mistake to suppose that Melons cannot be grown in ordinary loam, for add to it the soot and wood ashes, and, if deficient in humus a fourth of thoroughly decomposed manure free from worms, when it will grow almost any kind of fruit. Have the materials under cover a few days to dry, chop up the turf, and turn twice to thoroughly mix the ingredients.

Planting Cucumbers and Melons in Pits and Frames.—Have the beds made up about a week in advance of the plants becoming fit to plant out, employing sweetened materials, putting together compactly. Place a barrowful of soil in the centre of each light, flatten the top, which should be about 9 inches from the glass, and not more than 1 foot, the soil being about 10 inches deep. When warmed through place a plant in the centre of each hillock, press the soil firmly around each plant, keeping it about half an inch below the seed leaves, having the plant and soil in which it is planted moist, so as to prevent the need of water at planting. A circle of quicklime or dry soot drawn around each plant a little way from the stem will absorb superfluous moisture, and be a barrier against slugs.

Placing-out Cucumbers or Melons in Houses.—The house must be thoroughly cleansed, the woodwork with soft soap and hot water, glass with clean water only, both inside and outside, and wash the brickwork with hot lime. If there have been any eelworm scald the bed-walls with boiling water, and the bottom must be well soaked with it. Place the soil in a ridge, flattened at the top, and about 10 inches deep; and when warmed through turn a plant out in the centre of each light, or about 3 feet apart. Secure the stick to the bottom wire, and rub off the laterals up to the trellis. Maintain a night temperature of 65° to 70°, 70° to 75° by day, advancing to 85° or 90° from sun heat, keeping the bottom heat steady at 80° to 85°, or start at 90° if fermenting materials are used; but if from hot-water pipes 80° is sufficient, for fermenting materials lose heat, therefore it must be higher at the beginning.

THE KITCHEN GARDEN.

Manuring the Ground.—Advantage should be taken of the first moderately severe frost to wheel as much manure on the ground as it is intended to apply for the different crops. Comparatively fresh strawy stable manure is most suitable for the heavier soils, but those lighter and less retentive of moisture and fertility would respond to a dressing of mixed farmyard manure. Old mortar rubbish, sand, fine ashes, leaf soil, and burnt clay or fine soft ballast applied freely to heavy soils, forking them into the surface rather than burying deeply, serve to

keep them in a more finely divided and more fertile condition than formerly.

Digging and Trenching.—Where much digging has to be done an early start is desirable, but do not touch clayey ground while it is very wet on the surface. If it can be laid up in rough spits during this month, frosts and drying winds, followed by rains in February or March, may have the effect of pulverising it sufficiently to admit of its being got into a fine condition for seed sowing, also for Potato planting. If dug later, then the drying winds and sunshine in March and rain in April will have the same effect. Medium and light soils are less difficult to manage, though some of these ought not to be dug many days before cropping, owing to their liability to become badly saturated with moisture, which, if the ground had not been dug, would have passed away freely and naturally. Double digging and trenching ought to be done early in order to allow time for settlement. Never bring much virgin subsoil, and in particular any of clayey nature, to the surface at one time. A light surfacing may put new life into the top spit, but a whole spit of it, unless previously well prepared, might have the effect of making the ground sterile and unworkable.

Crops Requiring Manure.—Some soils give out much more quickly than others; but when a garden is closely cropped, and fresh rather than over-decayed manure is principally employed, it is not often too much is used. What the land does get sick of is an excess of humus, out of which the nitrogen, phosphates, and other elements have been washed or lost by evaporation. Those periodical dressings of old hotbed manure ought to be supplemented with or varied by an occasional dressing of newly slaked lime, applied at the rate of about half a bushel to the square rod every fourth or fifth year. Nearly every crop grown in a garden would require something more than humus, and those seasons when lime is not used artificial manures should be applied; those of a slow-acting nature, including superphosphate and kainit (potash), at cropping time, with a later dressing of the more quickly soluble nitrate of soda for the lighter soils, and sulphate of ammonia for the heavier ones. The ground ought to be most freely manured for Peas, Beans, Onions, Leeks, the Brassica tribe, Lettuce, and Tomatoes, Potatoes also paying well for liberal treatment. Supposing manure has been freely employed for previous crops, then little or none of it ought to be necessary for Beet, Carrots, Salsafy, Scorzonera, and Parsnips this season. Not only does strong manure make the roots of these grow too coarse, but it is also liable to fork them badly.

Seed Potatoes.—Far too many of these are stored in heaps during the late autumn and winter months, where they sprout prematurely and are greatly weakened accordingly. Ashleaf varieties in particular ought never to be pitted, nor is it wise to store them in bags, barrels, baskets, and deep boxes, as in these instances also premature sprouting has already become too pronounced. Lose no time in setting all early kidney seed Potatoes on their stalk ends in shallow boxes, packing them closely together. Store them in a cool, light position, covering closely only with paper mats or canvas whenever a severe frost is anticipated. In this way short stout sprouts will form, and the first step towards ultimate success assured. All other seed Potatoes ought also to be attended to, arranging them thinly in cool, dry, light quarters with a view to saving the first sprouts.

Early Peas.—Dwarf Peas may be successfully grown in pots, but are more profitable in pits and frames, whether these are glazed or only roughly protected. The 10-inch pot is a suitable size, and it must be three parts full with rich loamy soil. Sow the seeds thinly, press them in, and cover with 1 inch or rather more of fine soil. Not much water is wanted at first, but abundance of this and liquid manure will be required when the pots are well filled with roots. For frames and pits raise the plants moderately thickly in boxes of fine soil and place in heat. When 3 inches high all may be shaken out and replanted in beds of rich soil over a mild hotbed. Arrange the rows 15 inches apart, and plant moderately thickly, dropping the roots to their full depth in narrow trenches. Lightly stake and avoid undue coddling. Chelsea Gem is a good variety for pot and frame culture. If seed is sown in January on cold, wet soils much of it will perish; but if the weather keep mild and moderately dry, the early round-seeded varieties may be sown on lighter soils with a good prospect of an early crop resulting. With a little extra trouble, quite as early crops can be had by sowing the seed in boxes as advised for frames, or in 3½-inch pots, placing these under glass in little or no heat to germinate, and planting out when large enough.

PLANT HOUSES.

Palms.—During severe weather, when an excess of fire heat has to be used to maintain the desired temperature, thrips are liable to prove troublesome to these plants. A sharp look out must be kept for such pests, for if allowed to become established they soon injure the foliage, which may look unsightly for years. Once the insects make their appearance, sponge the fronds carefully with a solution of tobacco water in which a little soft soap has been dissolved, say 1 oz. to 4 gallons. After all have been sponged, fumigate the house once or twice in succession until every trace has been destroyed. Where these plants can be liberally syringed once or twice daily, according to the weather, they can, as a rule, be kept free from thrips but where the syringe cannot be freely used constant care and attention are needed. Do not overwater Palms at the roots, and, on the other hand, be careful not to allow them to become dust dry, or the foliage will soon present a sickly appearance. Maintain a night temperature of 60° where Kentias and other warm kinds are grown.

Adiantums.—Plants from which fronds have been gathered, and only small stuff remains, may be cut over and started again into growth.

If placed in a temperature of 55° to 60° they will soon commence pushing up new fronds, when they should be repotted without delay. If the plants need larger pots remove the drainage and any roots that may be crowded about the crocks; the remainder of the ball can be placed in the new pot without disturbance. If the plants are in pots large enough they may be divided by cutting them straight through the middle; the drainage should be removed and the plants potted without disturbing them further. The soil, which should consist of equal portions of good loam and leaf mould, with the addition of sand, must be pressed firmly into the pots. If the plants have been infested with small slugs thoroughly dust the crowns with soot. This will drive them out, and they can be picked off a short time afterwards. Continue this practice until the plants are perfectly free from these pests. A small white caterpillar-like grub occasionally infests these plants and feeds upon the crowns and young fronds just as they form to such an extent that seldom a perfect frond is allowed to develop. These can only be destroyed by thoroughly shaking away from the plants every particle of soil, when they roll out and can be destroyed. The best means of stamping them out is to burn any infested plants. After potting stand the plants on a moisture-holding base and syringe freely amongst the pots. Very little water will be needed until the plants commence to grow.

Gloxinias.—Any plants that are starting into growth where they have been stored away to rest will only draw up weakly if allowed to remain in a semi-dark place. The old soil may be shaken from the roots and the tubers soaked for a short time in tepid water and then left to drain thoroughly. After this they can either be potted singly or put in boxes amongst leaf mould and sand until they have well started into growth, when they can be placed singly in the pots in which they are intended to flower. Once the plants are started in pots we find they do well on a shelf fairly close to the glass, where the temperature ranges from 55° to 60°.

Eulalia japonica.—Plants that died down after use in the conservatory and have since been kept in a cool house may be removed to the forcing house or any structure where gentle warmth is maintained. They will soon commence to push new growths, when the plants may, if increased stock is needed, be divided into two, three, or more pieces according to their size. These plants are most useful in 5, 6, and 7-inch pots, and grow freely in any rich soil—good loam, sand, and one-seventh of manure will suit them very well. If gentle bottom heat can be given them after division they will soon become established, when cooler treatment will suit them well.

Begonia weltoniensis.—This is useful for conservatory decoration, as well as two or three other kinds of a similar nature. The earliest plants may be shortened back and placed in a temperature of 50° until they show signs of growth, when the old soil should be shaken from their roots and the plants repotted in a fresh compost. The plants can be placed in the same size pots or smaller. If the latter, they will soon need repotting. They will be found to succeed well in three parts of loam to one of leaf mould, with a liberal quantity of sand according to the texture of the loam, and one-seventh of old Mushroom bed refuse. Water with care until the plants are growing freely. They will start well in a vinery if no better position can be found for them.

Caladium argyrites.—A number of tubers should be started into growth; 2-inch pots are large enough in which to start them, or better still, place them in pans amongst light sandy soil, and after growth has commenced put them in pots. The pans or pots containing the tubers should be plunged amongst cocoa-nut fibre refuse in the propagating frame. Too much water at first often proves detrimental to them.

THE BEE-KEEPER.

SEASONABLE NOTES.

STARTING BEE-KEEPING.

THIS is a subject that requires some consideration, as judging from the numerous communications lately received, I am assured there are many readers of the *Journal of Horticulture* who are for the first time anticipating the pleasures of bee-keeping. To these I would say, Do not be daunted by a few failures, as there is no royal road to success; follow the advice given week by week in these pages, and if in doubt on any point, ask for information from the same source, and success should follow. Although there has been a succession of indifferent seasons for honey production, the present prospects are good. The winter up to the present has been mild, and the bees generally speaking are in good condition, but a mild winter is often followed by a cold spring, which is more trying to the bees than severe frosts at midwinter. At that season breeding is going on apace, and the worker bees have to be continually on the wing foraging for a supply of pollen and water so necessary for the feeding of the young bees. Many are thus lost owing to the cold winds and heavy showers prevailing.

The heavy rainfall experienced throughout the country lately is all in favour of a bountiful honey harvest. The weather is a great factor in honey production, a fact which should be kept in mind by all bee-keepers.

WHEN TO COMMENCE BEE-KEEPING.

To those who have had little experience in bee management I would recommend autumn or spring as suitable for making a start. If a colony of bees is obtained in the autumn there is the risk of their wintering safely, whereas if a start is not made until the spring there will be less danger of losing them, and as there is but little difference in the price the advantage is all in favour of the buyer.

A commencement might be made by purchasing a good stock of bees in a straw skep. They should be headed by a young queen bred during the previous season, and ought to weigh, including bees, stores, and skep, about 20 lbs. If of this weight in the early spring no feeding will be necessary, and if the weather is mild an early swarm may reasonably be expected. These should be placed in a frame hive on full sheets of comb foundation, and if given a little thin syrup for a few days will soon fill the hive with fully drawn-out combs, and be in prime condition to take full advantage of the honey flow when it comes.

The stock in the original straw skep will in all probability swarm again in about ten days from the time the first swarm left the hive. This is called a cast, and will be headed by a young unfertile queen. If the colony were a strong one, a second cast would probably come off within a few days. As this will also be headed by a young queen it should be placed in a separate hive next to the one containing the second swarm. The third swarm will be useless for storing a surplus of honey owing to there being so few bees, but the advantage to be derived from working them on this system will be readily seen at the end of the season, when the old queen which accompanied the first swarm may be destroyed, and the young queen from the third swarm introduced in its place. The bees must be united to the second swarm, and as the two stocks previously stood near each other no bees will be lost.

The bees remaining in the straw skep may be driven at the end of the honey harvest, and be placed in a frame hive and fed up for winter. If at all weak in bees they may be strengthened by taking a frame or two of brood and adhering bees from the other stocks. If worked on the above lines there will be three strong colonies for wintering, each headed by a young fertile queen, and if the season has been favourable a good surplus will have been stored by the first swarm.

An early swarm invariably works well, and for this reason, if only one stock is required, it is advisable to commence by obtaining a swarm, by purchase or otherwise; the earlier it is, the better chance of success. A swarm, too, may often be obtained several days, or even weeks, earlier by this means than if one depended solely on one stock.

It is well to remember that the old queen always goes with the first swarm, so that steps should be taken to introduce a young queen in due course. This may be done the following season, during the natural increase, as stated above. If an increase in the number of stocks is not required (but it is always advisable to have more than one) the old queen may be killed when the hive is well crowded with bees in the spring. A few days afterwards the combs should be examined, and all queen cells with the exception of one destroyed. The colony will thus in due course be headed by a young fertile queen.—AN ENGLISH BEE-KEEPER.

HIVES WITH TEN STANDARD FRAMES.

"AN ENGLISH BEE-KEEPER" (page 19) says when speaking of myself, "Your correspondent has not carefully read my previous notes on this subject or he would not have propounded the above query." I can assure "An English Bee-keeper" that I do read the articles in this *Journal* carefully, and my query was not a reflection on any system of management, but simply to turn on the search light in a friendly spirit. Your correspondent says, "I fail to see the advantage derived from allowing 100 lbs. of honey to remain in the body of the hive." So do I, for 30 lbs. is sufficient for winter stores.

The doubling system propounded by "An E. B. K." speaks well for large brood nests; the additional brood combs add to the strength of the hive. Does this not prove that ten standard frames do not give a hive strong enough for an "E. B. K."? To be candid, I do not like to extract frame combs that have been used in the brood nest. If we want the pure honey, and honeycomb of spotless whiteness, we must avoid combs from which bees have hatched.

Being the secretary of the Howdenshire Bee-keepers' Association, and having to call upon members, I have been able to compare results. Mr. W. Hall, Welham Bridge, told me that he has taken a good surplus from his large hives, containing twelve frames, 20 inches by 8½ inches, while hives with standard frames gave no surplus. Mr. W. Hall of Howden, who has a large apiary, tells me his hives with the 20 inches by 8½ inches last season did far the best. Where large hives are tried among the members of the Howdenshire B. K. A. they give the greatest satisfaction.—GEORGE HOWDENSHERE.

TO CORRESPONDENTS

All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Code of Judging (J. B.).—Write to the Secretary, R.H.S., 117, Victoria Street, London, S.W. The price is 1s. 1d., post free.

Price and Postage of Book (R. Lyon).—We cannot give the precise information you require, but you can obtain all particulars by writing to Messrs. George Bell & Sons, York Street, Covent Garden, London.

Night Soil for Vines—Nitrate (W. W.).—Night soil is one of the very best manures for Vines, especially that from earth closets, which contains a considerable amount of urine as well as solid matter, and there is little waste where sufficient dry earth is mixed with it to form a crumbling and easily applicable manure. Although the analysis be poor as compared with other fertilisers, it is a very satisfactory one in use, giving first-class results, especially with Vines, as it improves both the growth and finish of the Grapes to a striking extent. It should be applied without delay, as its constituents require some little time to become available as food for plants, a 2-inch thickness of top-dressing not being too much, but it should be pointed lightly into the soil. Nitrate (you do not say of what) would certainly promote growth in the Vines, but if you mean nitrate of soda it may not be desirable, as the soil is heavy, sulphate of ammonia being better, applying it not later than the starting of the Vines into growth, and about 1 oz. per square yard, or 2 lbs. per rod, pointing in lightly. If 2 ozs. of dissolved bones, dry and crumbling, were supplied at the same time it would be an advantage, still better with 1 oz. of double sulphate of potash and magnesia, or 4 ozs. of the mixture; sulphate of ammonia, one part; dissolved bones, two parts; double sulphate of potash and magnesia, one part. If, as you say, there is a tendency to sourness in the soil, add sulphate of lime four parts, and apply half pound of that mixture per square yard, pointing lightly in, not deferring application later than starting. If the night soil have about 10 per cent of air-slaked chalk lime, dry and floury, and dust charcoal, also perfectly dry, in equal proportions, mixed with it, the addition will improve it immensely for Vines and there will be little, if any, loss of ammonia, only use shortly after mixing. Ten per cent. means one part of the lime and charcoal to ten parts of the night soil.

Grafting Golden Yew on Two-year-old Shoots on Yew Hedge (B.).—The usual time of grafting Yews is in August, but you may practise it in the spring, first letting the sap flow freely in the stocks, or when the buds commence swelling. Select well matured growths of the Golden Yew some little time before then, and insert them in moist sand on the north side of a wall. It is well to proceed by side grafting, which means cutting a slice of bark and wood off one side of the stock, and then cutting the scion in such manner on one of its sides as to fit that made on the stock, so that the barks of both meet exactly, or at least on one side. Then a tongue can be made in the stock by a downward cut, and a slit in the scion upward, so that when this tongue is inserted in the slit of the stock and pushed downwards the barks of both will exactly coincide. It is well to leave a little growth or part of the stock above the junction, but not much, to draw the sap to it and insure "kitting," and also have a portion of the scion below the cut part long enough for placing in a phial of water to keep it fresh until the union is effected, securing the phial to the stock in the right place with lead wire. The scion should be properly bound to the stock with either matting or darning cotton, and then dress with either grafting wax or well tempered grafting clay, so as to completely exclude air from the junction. When the union has been effected, the ligature must be loosened, the part of the stock above the graft cut off neatly, and also the part of the scion below the union trimmed off, the first in an upward and the latter in a downward direction. The whole thing is much easier done than instructions given for doing it. If you do not proceed by what is known as bottle grafting, which we advise, whether you operate during the first fortnight of April or that of August, you must shade the graft after insertion, otherwise it may dry too much to unite with the stock.

The Currant Bud Mite (J. F. W.).—The Currant mite, belongs to a rather extensive group of minute creatures, which are by some naturalists placed amongst Crustaceæ, and by others classed with insects. Present opinion, however, rather tends to put them, with sundry allies, in a group called Aptera, insects the wings of which have somehow disappeared, and legs and transformations are apt to vary considerably. Those in the genus *Phytoptus* either make galls upon leaves or secrete themselves in the buds of plants, which then become "puffy" or contorted and shrivelled. A good deal of notice has been attracted recently to the proceedings of *P. Ribis*, more especially in the case of the Black Currant. Owing to its minuteness and its mode of life the species doubtless passes unseen in many instances. There is ample proof that this mite is lurking within the Currant buds by November, if not earlier.

FIG. 18.—"KNOTTED" CURRANT BUDS.

It is, however, during the spring that our attention is called to them, when by their feeding between the young leaflets, abstracting their sap, they effectually stop the development of flowers, leaves, and twigs. As Mr. Andrew Murray remarks, "the buds attacked are seen to languish and decay, or to assume a rounded swollen form without pushing out ('knotted,' some correspondents style it). On tearing open one, hundreds of very small semi-transparent moving things may be seen by a lens. All the surface of the leaflets on which they are scattered has a moist raw-like appearance; in fact, the *Phytopti* have browsed on it until they have flayed it to the quick." Close and severe pruning is the method suggested by this author for the diminishing of their numbers, but he scarcely thinks their extirpation can be thus brought about. Syringing or washing the bushes with one of the many solutions or compounds that are efficacious for the destruction of insects might clear some of them out of the expanding buds in spring, but would not save the buds from dying off. Then the bushes where the mite has been observed might be also syringed early in the autumn, since there may then be a migration from bud to bud. Bushes infested with this destructive mite should never be propagated from. Young trees should be procured that

are perfectly clean and healthy, and be planted as far distant as possible from those affected. We have seen perfectly healthy bushes and others seriously knotted in plantations less than 30 yards apart, and we have cut down affected bushes entirely, burning the branches, the resulting growths from the "stumps" of the decapitated trees being quite free from the pest; but if the mite exist on one plant it soon spreads through a plantation.

Eucharis Mite (Novice).—Go over the bulbs, and remove all decayed portions carefully. The three outer scales of the bulbs have been removed in some instances. In your case it may be necessary to remove one or more, then wash the bulbs thoroughly in tepid water, but before doing so remove every portion in which these mites can secrete themselves. After washing lay the bulbs in dry sand to harden the outer scales in order that they can bear a stronger solution of insecticide, in which they should be well dipped. Any favourite insecticide will do, and may be used the strength that would destroy aphides (green fly).

Exhibiting Blue Cornflowers in a Collection of Wild Flowers (Johnnie).—"Father thinks" rightly. Blue Cornflower (*Centaurea cyanus*) is a "wild" or British plant, and one of the showiest of the blue-flowered annuals. It may occasionally be found in cornfields in various parts of the southern counties, but we have not seen it wild further north than Hertfordshire, in which county it is found on calcareous gravelly soils, and rivals in colour of flowers and size of plant any grown in gardens. It is, however, or rather the people who do not mind reaping where they have not sown and trampling crops down to satisfy their selfish ends, a great nuisance, therefore farmers take care to have as little of it as possible in their cornfields, especially when there is a footpath frequented by town residents skirting or passing through them. It is called Bluebottle in some localities and "Blwets" in other districts, being known to every one as Cornflower from its growing wild in cornfields in various parts of Great Britain.

The Papyrus and its Use (Bothyite).—The celebrated Egyptian Papyrus (*Papyrus antiquorum*), or Egyptian Reed, from which the ancient Egyptians made their paper, still grows in the marshes of Egypt, or in stagnant waters of the Nile. It is also found in Sicily, Syria, and Nubia, and extends even to Senegal. This plant rises, with a triangular stem, to the height of 8 or 10 feet, and surmounted with a large compound umbel of flowers, having long filiform involucres, the lower part clothed with long, hollow, sword-shaped leaves, of a brown colour. The root-stocks are long and tortuous, 4 or 5 inches thick; when young they are sweet and nutritious, and are eaten by the inhabitants; they also yield a fecula, which, with the base of the stems roasted, they use as food, and they suck their juice in the same way as they do that of the sugar-cane. When old, the root-stock becomes hard and woody, and was converted into cups, moulds, and other utensils; one use of it was to make covers for binding the leaves of the books, which were made of the stem. The whole plant is used for making boats in Abyssinia, a piece of the Acacia tree being put in the bottom to serve as a keel. The leaves and the stem have been twisted into ropes, and with the vertical fibres cloth is made. The ancients made their paper from the pellicle found between the pith and bark of the thick part of the stalk, and the plant being called babee in Syria, this word furnished the appellation Papyrus, from which our word paper is derived. The pellicles were peeled from the stems and cut into strips of equal length; the strips were placed side by side on a board in sufficient number to form a sheet; other strips were placed side by side in an opposite direction over them, so as to make the sheet sufficiently thick and strong; each sheet was pressed, dried in the sun, and polished with a shell or some other substance, and twenty sheets or upwards were glued together to form a roll. The breadth of any roll depended on the length of the strips, and was usually from 10 to 13 fingers broad, and the length depended on the number of the sheets. With the rays of the umbels of the flowers the Egyptians made chaplets for the heads of their gods. Under the arm of a great many of the mummies a small bunch of papyrus is found. It was doubtless of this plant that the "ark of bulrushes" was made in which Pharaoh's daughter found the infant Moses.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. H. J.).—*Asparagus Sprengeri*. (C. O.).—All your specimens were dead. (S. G.).—A good form of *Lælia autumnalis*. (A. J.).—1, *Cattleya Walkeriana*; 2, *Cypripedium venustum*; 3, *C. insigne*.

ECONOMY WITH EFFICIENCY.

SEED time and harvest so far have never failed us; the primeval curse of thorns and thistles is still as potent as ever. Still, it is only by the sweat of the brow that necessary food is produced and there is no hope of things ever being different.

Soil must be turned to expose it to the genial influences of sun, rain, and frost; soil must be worked to rid it of noisome weed that would otherwise unchecked interfere with the growth of the infant plant, if not annihilate it altogether. The "grand old gardener," our first father, would have an implement of the simplest construction. How long manual labour alone was employed we do not know, but certainly at a very early period of the world's history the patient ox and ass were pressed into man's service, and some rude likeness of our present plough used. How rude, those who have travelled even to-day in the East can testify.

Nature is not so beneficent to us Western agriculturists, and it

is only by using the best implements at our disposal that we can effectually cope with her in her many moods.

There are some who would say "Good bye" to the plough. We have got rid of many implements used by our forefathers. To the modern child flail, sickle, and scythe are unknown tools met with only in the verse of the poet, but we think he would be a brave man who dare relegate the plough to the land of dreams alone. That there is a need for some reformation in the use of this implement is apparent. The profits of farming are so small that all possible economy must be exercised in every department. The labour bill has to be curtailed, and this must be done very judiciously, or it will prove but short-sighted policy, and in face of this shorter hours and larger wages are being demanded.

Horse keep is expensive, and horses cannot be kept for show; indeed it is questionable as to whether we employ the right kind of horse. Thoroughbred Shires, with their handsome proportions and slow and stately walk, are very ornamental, but is it not possible that their walk may be too slow, and the keeping of them in prime condition too expensive?

Granted that at five or six years old there is a ready sale for them for town purposes, would not a lighter horse do twice the work and be equally saleable? Of course this does not apply to those farmers who grow Shires as part of their rent makers—we mean those men whose reputation is made by the pure blood and grand constitution of their horses. We are speaking of the farmer who needs horses for everyday work, and plenty of it; who needs horses that can get over the ground quickly, and will not educate the men to majestic slowness of movement. Nothing spoils a good man more than a slow moving team, and how to get the work done quickly and thoroughly is the problem before us.

Men cried, "Eureka!" when the first of the large family of cultivators was introduced. Now was to be the golden age of agriculture; now no more foul land; now no more sweating horses; but, alas! the cultivator, though good in its way, did not fulfil the hopes of its advocates. Back they went to the old forsaken plough. True, the plough was undergoing many modifications, but still in principle it is the same. We must plough; how are we to do it in the best way and at the same time in the cheapest?

To begin with, we find ourselves confronted with two entirely different styles of ploughing. There is the deep winter ploughing, and the lighter work done in the spring, summer and autumn; and the celerity of the spring ploughing is often the greatest factor that goes to make the good crop. Now, as the two kinds of ploughing differ so materially—i.e., in depth—it is fair to ask, Do the ploughs differ in construction as much as they might, or do they differ at all?

The question of deep ploughing has long been before the public. On strong land it has been considered a necessity. Certainly it is the most expensive process in all the routine of farming. Given that it is necessary to deeply plough strong land, does it pay? It might when Wheat was 60s. per quarter; but now, at present prices and all things considered, would it not be better laid down to grass or planted?

Then as to medium land for Potato cultivation and ley land cleaning, it must be done to a certain extent; but we have many authorities on our side who agree that the crops are quite as good, if not better, with the shallower ploughing. Weeds are often buried only to be brought up again at great expense, and soil exposed that would have been better where it was—i.e., deep down.

An ordinary single-furrow plough and a pair of horses will turn over $1\frac{1}{2}$ acre per day; a lighter three-furrow plough with three quick-stepping horses ought and will plough 3 acres per day, and make a good job of it. The slowness of the team may be sometimes only the reflection of the slowness of the man; in fact, we once had a man whose sole object in life seemed to be to educate his horses to go as slowly as compatible with movement at all.

More power is got from horses by yoking them three abreast,

rather than in single file. Single file we never see in the north, and we fancy we do know how to economise labour. We do away with the boy, say at 10d. per day (further north it is 1s.), who leads the first horse.

For those who prefer the single furrow, there is no better plough than the chilled plough; it is lighter in draught and more efficacious in work than the old English pattern, and that it is a very useful implement is fully proved by the enormous numbers now in use. One great advantage of the chilled plough is that it leaves the land very light, so that one harrowing is generally sufficient before drilling, and what this means is fully comprehended by the farmer, who in spring has a large acreage to sow and very little time to do it in.

Far be it for us to urge a great multiplicity of implements on a farm, but it must be conceded that, to speak roughly, fine and coarse work cannot be done effectually by one and the same tool.

WORK ON THE HOME FARM.

Rain and fog are the principal features of the weather, and the land is as wet as ever. We are ploughing lea land for Oats, and though it is in a high and dry situation, and anything but of a strong nature, it turns up very wet and greasy. The plain fact is that the rain has no time to get away before more comes. The land ploughs well enough, but unless we have some sharp frosts the seed bed will be a stiff one.

We are hoping for a fine February. The seasons are now turned so topsy-turvy that February fill-dyke may belie its name, and give us the dry spell we so badly need. It is time to be crossing fallows, but it is of no use beginning until drier conditions prevail.

Manure is all led, so we have a chance to clear away refuse heaps and road scrapings. The latter are very beneficial to grass, and do the most good on places where the herbage is coarse, so that stock eat it badly.

We hear of serious losses amongst horses lying out, and they should be closely watched, so that if they are going wrong it may be detected in time. We know a farmer who had twenty-five young horses lying out, of which he has already lost six, and he fears more may die. The loss is attributed to wet lair, combined with insufficient food. Horses have been successfully wintered on the same land before, but it was not so wet, and the grass had more nature in it. We have heard of several other cases, and no doubt the season is chiefly to blame.

Turnips seem to be a little more plentiful, at least in this district, though we met a farmer the other day who already has his ewes on Mangolds, and he has more than 1000 of them. Fat ewes are coming to market very freely, and there are several sellers of Hoggs, so roots are not too plentiful with them.

Wheat grows well, and we have almost finished tenting; larks have pulled some up, but there is plenty left.

The young Clover is encouraged by the mildness of the season to commence growth, a fact quickly noted by the woodpigeons which are hovering about in large flocks. They will receive attention from the breechloader as usual. Only those who have seen it can realise the amount of damage these birds can effect.

REMARKS.

10th.—Dull and overcast, rain at 3 P.M., and slight fog in evening.
11th.—Dark, dull, and damp air all day.
12th.—Dark and dull, and overcast all day.
13th.—Overcast morning, fair about noon, then no sun rest of day.
14th.—Overcast early and at 9 A.M.; fair morning; bright sun at 1.30; overcast at 3 P.M., but fair after; rain in evening, about 7 P.M.; fine night.
15th.—Fair early and at 9 A.M.; bright sun at 10.45, and bright rest of day; fine night.
16th.—Fair early and at 9 A.M., and all the morning; snow at 6.45 to 1.30 A.M. (17th).
Another average week, with little sun.—G. J. SYMONS.

NOW READY.

BARR'S SEED GUIDE

For **1897.**

Barr's Seed Guide is full of practical hints, and is invaluable to Gardeners, Amateurs, and Exhibitors.

 FREE TO INTENDING PURCHASERS.

VEGETABLE SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Select List of the Best Vegetable Seeds for securing a supply of Vegetables "the year round."

FLOWER SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Choice List of the best Seeds for the Flower Garden and Greenhouse.

ALL SEEDS CARRIAGE PAID ON RECEIPT OF REMITTANCE

We guarantee all our Seeds to be of the finest selected strains, and of highest growing quality.

BARR & SONS

12 & 13, King Street, Covent Garden, LONDON.

ANT. ROOZEN & SON'S CHOICE VEGETABLE & FLOWER Seeds

FOR PRESENT SOWING,
AND

BULBS AND PLANTS

FOR SPRING PLANTING.

COLLECTIONS OF VEGETABLE AND FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM, HOLLAND, or to our General Agents,

Messrs. MERTENS & CO.,

3, CROSS LANE, LONDON, E.C.

No. 866.—VOL. XXXIV., THIRD SERIES.

Barter's TESTED SEEDS.

A FEW MORE
GOOD THINGS FOR THE GARDEN

CARTERS' HOLBORN EXHIBITION BRUSSELS SPROUTS.

A very fine strain, for size, solidity, and productiveness; it is preferred in Covent Garden Market to all others.

In Sealed Packets, price 1/6 each; 2/6 per oz., post free.

CARTERS' LEVIATHAN BROAD BEAN

The longest-podded Broad Bean grown; fine for exhibition, and one of the best for cooking purposes.

In Sealed Pkts., price 1/9 per Pint; 3/- per Quart, post free.

CARTERS' RED ELEPHANT CARROT

A veritable giant, both in length and rotundity. Specimens exhibited at our establishment measured 2½ feet in length.

In Sealed Packets, price 1/6 each, post free.

CARTERS' EXTRA EARLY AUTUMN GIANT CAULIFLOWER.

This magnificent variety is more dwarf, considerably earlier, and altogether better than the old form.

In Sealed Packets, price 2/- each, post free.

CARTERS' SOLID IVORY CELERY.

Still maintains its position as one of the best white Celeries in cultivation. A customer writes: "It was the only Celery we found good at the break-up of the intense frost."

In Sealed Packets, price 1/6 each, post free.

CARTERS' MODEL CUCUMBER.

Many so-called new Cucumbers are brought forward every season, but little is heard of them afterwards. This fine variety still maintains its position as the handsomest in cultivation.

In Sealed Packets, price 2/6 and 3/6 each, post free.

CARTERS' HOLBORN MODEL LEEK

Grand both for exhibition or table. A Welsh customer says: "They are the best we ever had."

In Sealed Packets, price 2/- each, post free.

CARTERS' RECORD ONION.

The largest Onion grown. A customer writes: "I cleared the whole roost in the Onion competition with 'Record.'"

In Sealed Packets, price 2/- each, post free.

THE CARTER SPINACH.

Mr. A. PETTIGREW, Head Gardener to the Earl of Bute, writes: "The best Spinach in cultivation; quite distinct from all others." Award of Merit R.H.S. trials, 1895.

In Sealed Pkts., price 2/6 per Pint; 6d. per oz., post free.

CARTERS' OUTDOOR TOMATO.

The very best for open-air cultivation we know of. Should be grown by everybody.

In Sealed Packets, price 2/6 each, post free.

Illustrated CATALOGUE, Gratis and Post Free.

TREE PLANTING.

THE DUTY OF ONE GENERATION TO ANOTHER

THERE is some little danger in our day, perhaps, under the pressing exigencies of the present with the ardent desire for immediate effect or quick results, to overlook in at least one phase of our work a duty to the future generation. Truly it may not be so to an alarming extent, but sufficiently so, I think, to make the matter worthy of consideration. Under the shallow reasoning advanced by a politician that posterity having done nothing for us therefore possesses no claims upon our attention, the matter might be summarily dismissed; but being as we are the posterity of a past generation, and tacitly acknowledging the debt which in the enjoyment of its well-planned work is incurred by us, the responsibility is not thus to be comfortably disposed of.

Gardeners of to-day are not as a rule, I fear, so well skilled in arboriculture as its importance deserves and demands, and when considering the manifold things that modern society requires at their hands, it is not a matter for surprise that it is so. We admit, of course, that in the spacious surroundings of "the stately homes" shortcomings in this respect are few and far between; yet even here sufficient evidence may be found to point a moral, for in some of them at least crippled resources, whilst not shutting from view the duty to futurity, cause it to be carried out in a hurried or perfunctory manner. Such work, too, is often entrusted to a man—a capable general manager may be—having charge of all in the demesne outside the garden proper, but one whose knowledge of our subject may be very limited, and who relegates the duty of planting to a few labourers, who know as little and care less. Anyway, such is my experience from observation.

One demesne, whose owner was as anxious to do for his descendants as much as his ancestors had done for him, provides an illustration to this point of the text. Here amongst the "tall ancestral trees" some superb Cedars of Lebanon were a feature, and it was this worthy proprietor's express desire that his farm bailiff, who superintended the keeping of the demesne, should

plant more Cedars in suitable positions. This was done several years in succession, but ill done, all but total failure resulting. The cause was not far to seek, for although good plants were procured (too good in fact), and in good time, they were "heeled in" to be at the last moment stuck, not planted, in their positions and stuck there to die. I was present when the matter was broached between the two most interested persons, and standing within 50 yards of one of those superb specimens previously mentioned; the reply to the query as to the failure of the young trees was, "Oh, the soil is not suitable." One could not but pity the man whose only resource to excuse shiftless planting was so palpably absurd, and the rapid look of his employer from the grand old Cedar to me revealed the thought, not otherwise expressed, which was in his mind.

Thriving trees must ever be a source of pride to the planter, as they may eventually prove to be the most enduring monuments of his forethought and good work. One fails to see how anyone whose cultivated taste begets the full enjoyment of noble trees can overlook the duty of one generation to another, either in judicious planting or in the preservation of venerable relics of the past. I could point to a dozen places, of some pretensions too, where future arboreal effect is entirely ignored in the passive enjoyment of the present, or the question is indefinitely postponed under the compound pressure so few places have escaped. Others there are in which a desire for novelty has led to the planting of many of the more recently introduced Coniferae, which must be regarded to more or less extent as experimental, but which have monopolised attention to the exclusion of equally worthy and more reliable objects of our solicitude.

Some trees in their infancy resemble children, in so far as that character is concerned with which we imbue the latter when remarking that plain features often develop later charms, or *vice versa*. Many who admit this so far as our own species are concerned appear to be led astray by the infantile beauty characterising some trees of modern introduction. What a gay deceiver is *Cedrus Deodara* in its graceful and elegant youth! It is and has been planted in prominent situations with the object of becoming a permanent feature when its noble cousin, *C. Libani*, would under normal conditions yield unqualified satisfaction. As an ornamental plant, up to a certain stage the Deodar has few equals, and probably none that can surpass it in beauty; but after a certain stage (not age, of that more anon) its glory has departed, and there is not, I fear, anything remaining to make it worthy of our consideration as a permanent object. From a timber point of view its commercial value is not, probably, great, and its character as a factor on this account is doubtful. It was, I am aware, awarded high meed of praise some few decades ago by very competent authorities on Coniferae, but I do not know of any instance in which those expectations have been, or are likely to be, realised.

In a sheltered glen where a collection of choice Coniferae have developed into good specimens (a good specimen is not necessarily a thing of beauty) a Deodar which has thriven remarkably well so far as thriving goes is in its appearance the one black sheep of the flock. Lately a gentleman, certainly uninitiated in woodcraft, and to whom I was expatiating on the subject whilst pointing out the specimens, admired them very much, but said, "Why did they plant that ugly Fir tree in so prominent a place?" Alas! for the departed glory of *Cedrus Deodara*, which was the tree in question. Very probably admirable specimens of this Cedar exist that I am unaware of, and very probably, too, if such is the case, they are to be found where unremitting attention to top-dressing has contributed to the preservation of that unique feathery gracefulness marking their distinguished youth. Biennial pruning to keep the Deodar within limited bounds will, I believe, accomplish the object of retaining it as an ornamental tree practically irrespective of age.

Noting the splendid effects that are obtained by liberal and

frequent top-dressing and other extraordinary attentions paid (and worthily paid) to various trees, we can only conclude that the practice is highly commendable. Yet this is but a side-light of that broad view the subject demands. There are but few, if any, places where the practice obtains beyond the pinetum or other limited area, and it would be presumptuous to predict in the mutable conditions under which we live that such benefits may be continued far enough to reach another generation. All honour to a generous-hearted patroness of horticulture and arboriculture of a past generation, who gathered about her delightful home the good and beautiful of tree life from many lands; yet her estimable qualities were rather those of the heart than of the head is now sadly in evidence. It is painful to see where so much was attempted the many silent witnesses still standing to point a moral, obvious enough to the most casual observer, of mistaken enterprise and enthusiasm; and in looking at what is, the context of what might have been is not less apparent. For instance, the well-formed sweeping avenue of *Araucarias*, many sickly, struggling survivors, of which more pitifully tell the tale than any words of mine could, force such invidious comparisons upon one's mind. Probably if a little more thought was given to the matter the somewhat narrow view of our own allotted span would be merged into the subject of our text—the life of a noble tree from infancy to prime and on to its undimmed glory of venerable age.

It is for gardeners to consider this phase of the subject. On the larger scale, or in its commercial aspect, it may well be left to the skilled forester. Gardeners, too, are in this matter a power for good if they will give the subject a place in their hearts among their pet *Chrysanthemums*, *Roses*, or other deserving if often all-engrossing objects of their care. And gardeners, too, are a power for evil if, when compelled by duty to give some attention to the matter, they only give as little as possible ere hurrying back to their hobbies for fear of some coveted trophy in competition going astray. The subject is a noble one, and provides a theme which might well be extended. It is not intended to do so now; later on some thoughts on tree pruning may be expressed. In commencing this paper its object was specified; in concluding it I may be permitted to lay down a few broad lines capable of being stretched to suit all cases, but which should never be lost sight of.

Consider why you should plant, what you will plant, how you will plant, and where you will plant. These simple points are worth all the consideration that can possibly be given to them. In handling the infant tree grasp all the possibilities of futurity as a guide to ultimate space required. If as a single specimen, think of "The grandeur of the lonely tree that wrestles singly with the gale." In grouping, how many incongruities have been perpetrated by the planter in his desire for unlimited variety within limited space! There may be beautiful and desirable trees among them,

"But more majestic far they stand when side by side their ranks they form,
To wave on high their plumes of green, and fight their battles with the storm."

—SYLVA.

ZYGOCOLAX VEITCHII.

THIS, "Junior," is one of the most interesting bigeneric hybrids, and it was introduced in 1893. It is the result of a cross between *Colax jugosus* and *Zogopetalum Mackayi* var. *crinitum*, the former being the pollen and the latter the seed parent. It is undoubtedly one of the happiest of the Veitchian hybridiser's efforts in the inter-crossing of Orchids, the blending of the characters of the two plants being effected in a most pleasing and harmonious manner. The form of the flower is accurately portrayed by the engraving (fig. 19); it will suffice, therefore, to describe the colouring. The

sepals and petals are pale greenish yellow blotched with chocolate. The short, nearly flat, and very broad lip is pale lilac veined with rosy purple and margined with the same colour. The habit is dwarf, the pseudo-bulbs short and blunt, the leaves, as shown, long and narrow. There is a strong suggestion of the *Zygopetalum* parentage about the hybrid, but it is, as it were, modified and toned down, the contour of the flower being improved by the "Colax blood." In every respect *Zygocolax Veitchi* is a beautiful and charming Orchid, and a distinct triumph of the hybridiser.

SACCOLABIUM GIGANTEUM.

THIS is the brightest and most effective of all the distichous-leaved section, flowering during winter, and an Orchid worthy a place in the most select collections. Its great fleshy leaves and apparently vigorous habit hold out hopes of a robust and healthy constitution, which unfortunately it does not possess. Newly imported plants, it is true, are easily established, and for the first few seasons no fault can be found with its behaviour; but, as a rule, after this time a backward tendency becomes apparent that is difficult indeed to resist. Often the plants will go on well until it becomes necessary to give them new material at the roots, then when they are once disturbed it is difficult to get them to take a good hold on the new material.

The symptoms of this unsatisfactory state vary somewhat in individual plants, but as a rule the foliage begins to shrivel considerably, gets loose at the axils, and eventually drops off, lessening the size of the plant, and of course in a like measure its vigour. This is occasionally the result, too, of allowing weaker or unestablished specimens to flower freely, their blooming season being, as before mentioned, the middle of winter, when the energies of the plant are at their lowest ebb. But this alone would not cause so many fine plants to be lost annually, and the secret really lies in our artificial atmosphere. Too many Orchid houses are built nowadays very narrow and low, and admirable as these are for a great many Orchids, they are not quite the thing for this class, which above all others need plenty of head and elbow room.

Given a large roomy structure, where the plants may be arranged at least a yard from the glass, and where owing to the capacity of the house the atmosphere is not liable to sudden alternations of drought and moisture, these plants are far more likely to be satisfactory than in the class of house aforesaid. I have an idea, too, that the proximity of larger specimens of vegetation, such as big Palms, Tree Ferns, Musas, and other things frequently seen in large stove conservatories, is helpful in providing the right kind of atmosphere, and certainly the broken light coming between the foliage of such plants is better than that caused by the close shading practised in Orchid houses generally.

As a rule, this class of house is not at command, and growers must do the best they can with those they have. Provide them an atmosphere quickened by plenty of heat, yet not stuffy, and let air and moisture be as nicely balanced as outside conditions will allow. Shade as little as possible, but never allow the foliage to feel hot to the touch of a person in the same house. This must be kept up the whole year round, for *S. giganteum* is a restless species, and is frequently in growth again almost before the flowers are past. If they seem inclined to rest awhile do not try to force them into growth; but, on the other hand, when once root action commences a deal of harm may be done if any attempt to check this is made.

Imported plants usually arrive in fairly good order, and in many cases they may be potted up at once in clean crocks, or placed in baskets in the same material if these are preferred. Roots will be emitted in due course, and when these are seen to be starting lay a surfacing of sphagnum moss over the crocks, this protecting the young roots and husbanding the moisture. In a warm house they will require frequent watering, and owing to the nature of the material the roots are not in the least likely to be surfeited with ordinary care. Should the plants, on the other hand, be much shrivelled when they arrive, suspend them upside down in a warm moist house until they are plumped up, and ready to pot as described.

Established plants, as mentioned above, dislike disturbance at the roots, but if it becomes really necessary it must be gone about in a careful and judicious manner. The best time to repot is after the flowers are past, and just as the plants commence to grow, they being allowed a little more warmth afterwards, and carefully watered. I have advised the use of pots, as I believe the roots of all distichous species have a great liking for the hard, yet porous earthenware, but they should in all cases be suspended if convenient. They must never hang direct from a rafter unless this is provided with a drip groove, for cold drops in the centre of the plant at midwinter will kill it as surely as if it was exposed to frost.—H. R. R.

NOTES FROM THE RIVIERA.

HAVING spent a period of twelve months in this charming part of the Continent, perhaps a few notes made during my sojourn there may be of some interest to readers of the Journal. The chief towns in the Riviera—Nice, Cannes, Monaco, and Mentone—are all well-known winter resorts, the population of which during this season is almost doubled by the influx of visitors. A large number of these are English, who no doubt are very glad to be able to leave their foggy island home for the almost unbroken sunshine of the South of France. It is seldom that much frost is experienced, 4° or 5° Fahr. being the most registered in ordinary seasons. The winter of 1894 was exceptionally severe. We then had as many as 12° of frost and a heavy fall of snow, which did a great deal of damage to the vegetation of the gardens. The summer is hot and dry; sometimes the thermometer in the shade reaches 100° Fahr. Little if any rain falls from the end of April to the beginning of October. The scenery of the Riviera is most charming; indeed, Monte Carlo has been described as the "most

FIG. 19.—ZYGOCOLAX VEITCHI.

beautiful spot on earth." All the previously mentioned towns have a fine situation, and each is well sheltered on the north by the Eslerel Mountains, running parallel with the sea coast. Nestling on their well-wooded slopes, with the blue Mediterranean stretching away in front and a cloudless sky above, these towns present an ideal picture.

Without further enlarging upon the beauty of this neighbourhood, I will turn for a short time to its horticultural aspect. The commonest trees which flourish here are the Pine, Olive, Orange, Eucalyptus, Plane, and Acacia. The Olive tree is very useful, for besides withstanding well the summer drought, it seldom fails to yield a large crop of fruit, chiefly used for making oil. Cooked Olives are also largely consumed by the French and Italians. The under side of the leaves of the Olive is much lighter than the upper surface, in fact almost white, and in a rough wind the constant changing of colour produces a pretty undulating effect. The Eucalyptus (*E. globulus*) attains a great height, almost as high as our English Elms, but although a handsome tree it is not a favourite with gardeners here, as its strong roots travel a long distance, and deprive the soil of much nourishment. I have seen instances where nothing would grow within many yards of this tree. The Plane (*Platanus orientalis*) is largely used for planting avenues and boulevards in towns, where its shade is very acceptable during the hot summer days. Both at Nice and Cannes there are splendid avenues.

I think one of the prettiest sights to be seen here in the months

of January and February is the Acacia in flower. The trees are literally a mass of yellow, and seen in the bright sunshine the effect is not likely to be forgotten. Groves of Orange trees are usually planted on terraces formed in the hill sides, as unless this were done, of course there would be no means of watering them in the dry weather. Large quantities of the blossom are gathered every spring, and sent to Grasse, there to be used for making scent, the fruits being picked in the autumn and sent to market. There are two species of Pine indigenous to this district, *P. maritima* and *P. pinea*. The former grows abundantly on the rocky ground by the seashore. The Umbrella Pine, as *P. pinea* is called, from its resemblance in shape to that useful article, is more rarely met with. The gardens of the Riviera are not at all ancient, most of them having been made within the last forty or fifty years. Indeed, before that time this shore of the Mediterranean as a winter resort was only in its infancy, and the towns that have since sprung up were nothing but mere villages.

Although of comparatively recent formation, these gardens have now both beautiful and varied vegetation, quite tropical in character. Palms of various kinds are the principal decorative plants employed, and some of these have grown into veritable giants. *Phoenix canariensis*, *dactylifera* and *reclinata*; *Cocos plumosa* and *australis*, *Chamerops excelsa*, *Pritchardia filifera*, *Sabal Blackburneana* and *umbraculifera*, *Jubea spectabilis*, and *Cycas revoluta* are found in most gardens. Bamboos grow freely, and form magnificent clumps, 30 to 40 feet high. *Aralia Sieboldi*, *Dracenas*, *Yuccas*, *Agaves*, and *Camellias* are common objects in every garden. The *Agaves* are generally planted in bold groups amongst rockwork, as this situation shows them off well. The principal varieties are *A. ferox americana*, *A. variegata*, *applanata*, and *Salmiana*. *Magnolia grandiflora* grows quite 60 feet high, and when in flower is a beautiful sight. *Acacias dealbata*, *cyano-phylla*, *cultriformis*, and *longifolia* are also generally cultivated.

The routine work in the Riviera is very different from that followed in our English gardens. In April, when all visitors have returned northwards, the lawns are dug roughly over with a spade, in which state they are left all through the summer and have almost the appearance of ploughed fields. It is quite necessary, however, to treat them in this fashion, as the grass would be completely burnt up by the hot sun. In October they are levelled and resown. It reminds one forcibly of spring time in England to see the green blades of grass appearing above ground, and the freshness of the surrounding vegetation after the rains also helps to convey the same idea. The newly sown lawns are often damaged and sometimes partly washed away by the heavy autumn rains. Every garden is provided with stone gutters by the sides of the walks, but even these are often insufficient to carry off the water quickly enough.

From November to April the flower beds are gay with flowering plants and bulbs. For this purpose quantities of *Cinerarias*, *Primulas*, *Daisies*, and *Pansies* are grown from seed every year. *Anemones*, *Hyacinths*, *Tulips*, *Ranunculus*, and *Freesias* are planted in beds covered with white moss, which is found on the neighbouring hills. The moss serves as a background for the flowers, and greatly enhances their beauty. *Carnations*, *Violets*, *Salvias*, *Stocks*, *Pyrethrums*, and *Solanums* are also used for bedding out. *Roses* are in full bloom in the early months of the year. They are generally grown as bushes. *Marie Van Houtte*, *Général Jacqueminot*, *Perle des Jardins*, *Safrano*, *Paul Nabonnand*, and *La France* are well-known varieties here. The *Banksian Roses* are generally covered with blossoms; they flower rather earlier in the season.

I cannot omit to mention the hardy (in this district) creepers, which to my mind are a feature of the Riviera gardens. Almost all the villas are covered with some of these plants. *Bougainvillea spectabilis* is, I think, employed more than any other. Its flowers are of a deep red colour, and open in January. Our old favourite *Wistaria sinensis*, *Kennedya ovata*, *Cobaea scandens*, *Tecoma Smithi*, *Bignonia Tweediana*, *Solanum jasminoides*, *Plumbago capensis*, *Lotus peliorhyncus*, and others. All these flower in the sunny south during our dark and dreary winter.

I should like, in conclusion, to mention a few of the most notable gardens in this part of France. At Grasse, a town several miles inland from Cannes, Baroness Alice Rothschild has a large well-kept domain. It is situated on the side of a steep, high hill, which is gradually being transformed into an Alpine garden, and, I am sure a more ideal place for this purpose could not be wished for. Palms do not grow so well here, perhaps on account of the very cold winds sometimes experienced. Cannes contains many fine establishments, including that of Lord Brougham, famous for its splendid Rose bushes, one of which, *Marie Van Houtte*, is about 15 feet high, and the same in diameter. Baron Alp. Rothschild's winter residence is also at Cannes. To furnish the flower garden, quite 50,000 bulbs, *Hyacinths*, *Tulips*, *Anemones*, *Ranunculus*, and others are grown. The garden at Villa Valetta is one of the oldest on

this coast. It has some very good specimens of Palms, and several nice Tree Ferns, but these are often caught by the frost. Antibes is the home of the Riviera nurserymen. Here Messrs. Vilmorin have large seed grounds for the cultivation of such plants as *Cannas*, *Begonias*, and *Primulas*. The Antibes Botanical Garden is interesting. It has good collections of Palms, Conifers, *Eucalyptus*, *Callistemons*, and various other kinds. There is a tree of *Jubea spectabilis* here, believed to be the largest in Europe, but I do not know its measurement. The Casino gardens at Monte Carlo are very beautiful. They contain unusually fine trees of *Ficus macrophylla*, almost the size of our Chestnut trees.

Just across the Italian frontier is the well-known garden of Mr. Hanbury. Many plants do well here that will not thrive farther west, as *Kentias*, for instance, which grow outside without protection. The *Agaves* and *Aloes* are remarkably fine; *Grevillea robusta*, *Callicarpa purpurea*, *Streptosolon Jamesoni*, *Bignonias*, *Ericas*, *Acacias*, all add to the beauty of this wonderful garden. But we have now entered foreign territory, so my wandering pen must be recalled, and bidden cease its labours.—H. H.

[A pen of promise as guided by the young gardener behind it, and should not rest from its labours too long.]

A GARDEN IN THE ISLE OF WIGHT.

[An Address (amplified) by Rev. H. EWBANK to the members of the Horticultural Association at Newport.]

(Continued from page 58.)

THE first flower in the year about which I would say a word is a very humble one—*Eranthis hyemalis* (the Winter Aconite); it might almost be called the last flower, for where it is grown in quantity it is sure to put in an appearance before the old year has closed. *Eranthis hyemalis* has a place for me in the garden of memories. An old uncle in Yorkshire, who taught me to garden more than fifty years ago, used always to say that the Winter Aconite never failed him on the last day of the year, and I say just the same thing now in the Isle of Wight. This little flower carries me back more than anything else I have to the days of my boyhood. It will grow anywhere—in the open or under trees—and it soon comes to make a veritable cloth of gold, and is so bright and cheerful that I would not be without it on any account. There is a new one which has lately been introduced from Asia Minor, and of which I have two or three good clumps, owing to the kindness of Mr. Whittall of Smyrna, but though I am very glad to possess it I think I shall prefer my old friend, for I am told that *Eranthis cilicica*, which resembles *E. hyemalis* in all respects save one, blossoms at quite a different time of the year; and this cheery little plant must always want a background of winter, which it enlivens so well.

The next flower is one which cannot be too highly recommended, but which, so far as my experience goes, is not often seen. I refer to *Cyclamen Coum*, which blossoms in the dead of the winter, coming up very often through ice and snow, and laughing the cold to scorn. It may be either red, pink, or white, and it seems so lively when all around is drear and desolate in the extreme. I have seen persons jump when they came across the patches of red on my rockery for the first time, and found some colour in the garden when they had looked for none. *Cyclamen Coum* comes from the South of Europe, and is very easily grown. It is not so large as *Cyclamen europæum*, and has round leaves, which differ from those of the other sorts. In the earlier stages of growth they are quite red underneath, which afterwards turns to green. In the case of other *Cyclamens* the leaves come from the centre of the plant and bend gracefully to the ground at the side, while the flowers, each mounted on a stout single rootstalk, stand up above the foliage, and form a perfect bouquet of beauty over the corm. It is rather different from this with *Cyclamen Coum*, the leafstalks or petioles are very short as well as weak, so that the leaves often lie on the ground rather than rise up. The corolla is also short and somewhat constricted at the mouth, where there is generally a white circle around it. This *Cyclamen*, like *Eranthis hyemalis*, will grow anywhere, either in sun or shade. It is fond of leaf mould and old mortar, but it is by no means exacting about it, and when once it has taken possession of the ground it multiplies itself with extraordinary rapidity, and has a great progeny of its own. The late Mr. Atkins of Painswick was a great cultivator of *Cyclamens*, and the varieties which bear his name are rather larger than the type, and are an improvement on it. His idea was that the tuber should in all cases be just buried beneath the surface of the earth.

The *Cyclamen* has a curious habit, from which beyond a doubt it takes its name, "of forming its seed vessel after flowering, which then hangs down, and by a succession of coils of the flower stem is brought to the ground and there buried." It belongs to the Primrose family, but this very strange performance is quite peculiar to it. In Parkinson's "Paradise" it is always made to bear the name of Sowbread, but why it should be so is not clear. It can scarcely be because swine are devoted to it, for Canon Ellacombe tells us in his "Notes in a Gloucestershire Garden" that on one occasion some pigs made an inroad into his garden, but they turned up their noses at a large spread of Sowbread, and turned them into other things by preference to it. The colour of *Cyclamen Coum* is so good, the time of year at which it blossoms is so drear, it has such a nice way about it, that if I had a garden which is no bigger than a pocket-handkerchief I would grow these *Cyclamens* in one corner of it.

The companion of Cyclamen Coum is the Snowdrop; it blossoms at the same time, and no words of mine are needed in its praise. It has many pretty names—and some of them are very expressive—but none are better or so good as its familiar English name. It seems to have been described as the "bulbous Violet" towards the close of the seventeenth century, but that is an unsuitable appellation. The "Snow-piercer" of the French is a much better name. The "Milk Flower" of the Germans might have done, but the best of all names is Snowdrop, because it exactly expresses what the flower seems to be. Mrs. Barbauld must have thought of this when she wrote—

"As Flora's breath by some transforming power
Had changed an icicle into a flower."

It has always been considered to be an emblem of consolation—a herald of hope—but that can only apply to one or two particular species—e.g., *Galanthus nivalis*, which blossoms in midwinter; the others take very different times of the year—in the autumn and in the spring. Of the Snowdrop, however, that most of us know best, this may be said—

"Green hues of hope array us,
Our snowy bells must ring,
And low but sweetly chiming
The joyful tidings bring;
For theirs it is to utter—
Awake! behold the spring."

The above lines are quoted from Dr. Forbes Watson's essay and Sowerby's "British Botany."

Dr. Forbes Watson made a great study of the Snowdrop, and on his deathbed wrote a beautiful essay, of which I will quote to you a few lines. His great point is that the expressiveness of the Snowdrop depends on its double drop, and this comes from its belonging to the order of the Amaryllidaceæ and not to the Liliaceæ—which orders, however, are to the eye, except in this one respect, very much alike. His words are these:—"Suppose that the Snowdrop had been a Liliaceous instead of an Amaryllidaceous plant, its whole significance would have been changed. The two orders so nearly resemble each other that no visible change would be needed except one—that the green drop-like ovary would be contained within the corolla instead of being outside it, and thus the form of the double drop would be lost, for the corolla would spring directly from the flower stalk. We may notice also," he says, "when the flower is closed and the fitness of the name most manifestly seen, how the white corolla—so narrow where it leaves the ovary—lets its fulness run down into the tip so as to give the form of a dewdrop just parting from the stalk which bears it."

These seem to me most beautiful reflections, and which would have occurred only to a very cultivated mind. *Galanthus nivalis*, as you know, will grow anywhere, but some of the other species are very troublesome indeed. *Galanthus octobrensis* was discovered by Lord Walsingham when he was hunting in Albania, and he introduced it into cultivation. As its name imports it blossoms in October, and *G. præcox* or *coreyrensis* comes even before that. *G. Redoutei* or *latifolius* is one of the last to blossom; its broad strap-shaped leaves are not glaucous, but of a deep green colour; it winds up the series in March, so that it is very possible to have Snowdrops with us for nearly six months in the year. The Snowdrop specialist of the present day is Mr. James Allen of Shepton Mallet. He is a great friend of mine, and I have often tried to pick his brains. He has given me some varieties of his own selection which are extraordinarily lovely. He says that from some reason or other Snowdrops do best when they are planted among the roots of trees, and I almost think that it is so. I have a new Snowdrop—*Galanthus Fosteri*—which is coming up now in quantity under the shade of a large Elm, and I find it much more amenable to reason than had been previously the case. The roots of the tree seem in some way to ventilate the soil and to keep it sweet, and at any rate *Galanthus Fosteri*—which is reputedly a very difficult plant to manage—is quite at home there. It may be added that this Snowdrop has leaves which are similar to those of *G. Redoutei*, and is a very fine one. I think that they should all be planted deeply in the ground, and then they should be left alone as much as possible. They seem to me to like a rich soil where leaf mould largely predominates, and under such circumstances as these they are sure to increase.

I have two curious little Snowdrops which are rather scarce—*G. flavescens* and *G. lutescens*. They are unlike their congeners in having a yellow ovary, and they are said in some way to differ from each other, but what the difference is I do not see. *G. Sharlocki* is a perfect oddity, and looks like a Snowdrop which has gone out of its mind. The outside tips of each outer petal are green, the upper portions are white, and it has a two-leaved spathe which stands up in a most funny way on either side of the flower, and reminds me of Mr. Gladstone's shirt collars as they are represented in "Punch." In contradistinction to this strange apparition some mention should be made of *G. pucilliformis*, which is a form of *G. nivalis*, and perhaps the most perfectly shaped of all known Snowdrops. The inner segments of the corolla are elongated and close inwards, and its very beautiful form leaves nothing to be desired. The only drawback to this extremely pretty Snowdrop is that it has a very tender constitution. It has, alas! parted company with me, and its place knows it no more. Snowdrops seem to me to follow one of two patterns—they are globose and floppy like *G. Elwesii* or more pendent and refined like *G. Imperati*. There are several others beside those I have named. It should be added that my collection of Snowdrops has been very largely improved by Mr. Whittall's munificence. *G. Cassaba*, *G. Ikariæ*, and two or three more are very fine things, and are

already taking high rank as they become more known and better established in the ground.

The Christmas Rose—*Helleborus niger*—claims a word at my hands. It belongs to a genus which has about a dozen species, two of which—*H. foetidus* and *H. viridis*—are found in Great Britain. I have no particular difficulty with any of them, though I think they would be glad to have more shade in my garden. *H. niger* blossoms in midwinter, and is always welcome then, for it is pure white, and rivals the snow itself. There is a large farm for Christmas Roses near Bath, and they ought to be very profitable flowers, as coming in at the right time of the year. The Bath variety is a very good one, and much in request. *H. maximus* blossoms about a month or six weeks earlier, and is a very fine plant. It hails from Aberdeen.

I am very fond of *H. angustifolius*, which was highly prized by the late Mr. Brockbank, and I think all he said in its favour is borne out by facts. It is curious to read what Parkinson wrote more than 200 years ago about the true blacke Hellebor or Christmas flower, as he calls it. His words are these:—"The flowers have the most beautiful aspect, and at the time of flowering are most rare. The true blacke Hellebor, or Bearefoot as some would call it, hath many fair greene leaves rising from the roote, each of them standing on a thicke round fleshy stiffe greene stalke, about an handbreadth high from the ground, divided into seven, eight, or nine parts or leaves, and each of them nicked or dented from the middle of the leafe to the pointward on both sides, abiding all the winter, at which time the flowers rise up on such thicke stalks as the leaves stand in, every one by itself, without any leafe thereon, for most part consisting of five broad white leaves—like unto a great white single Rose—with many pale yellow thrums in the middle standing about a green head, which after groweth to have divers couds set together pointed at the ends like horns, &c., &c." Such was the description of our old favourite *Helleborus niger* before botany grew into a science, but I think it can be followed even at the present day.

It may be as well just to mention two or three other Hellebores which no garden should be without. *H. purpurascens* has large flowers, dove-coloured inside and out; it is one of the earliest to bloom, and is a native of Hungary. *H. orientalis*, from Greece, is very free indeed, and some of its varieties, such as *H. antiquorum* and *H. guttatus*, are of great value. *H. abschasicus*, from the Caucasus, is one of the parents of a large race of hybrids at Berlin, itself also being of merit. *H. colchicus* is of a deep bright plum colour, with sepals which are somewhat round and flat, and yellow stamens. It blossoms in March, and should find a welcome place with all lovers of flowers. *H. angustifolius* is more curious, I think, than beautiful. It comes from Corsica, and resembles a young Holly more than anything else. There are some two or three other species of merit which I have besides these. But I think this notice of Hellebores may be closed with just naming two acquisitions which came to me from Herr Max Leichtlin of Baden Baden. They are *H. lacteus* and *H. Madame Fourcade*. The former is of such a precocious disposition that it seems to be thinking of winter before the summer is closed, and the latter is admittedly a hybrid of the highest beauty and excellence.

(To be continued.)

CAULIFLOWERS.

To a large extent the uncertainty and inconvenience of wintering Cauliflowers in frames and pots for the early summer supplies is greatly minimised, and has become in many gardens a thing of the past. Nor is it at all necessary since the introduction of the early forcing varieties of this nutritious vegetable. Of course we do not from this section get large heads, but it is a well known fact that they are the size most prized for the table, as they can then be served whole, and it is certain they present a much more appetising appearance served thus than is the case when large heads have to be used, as dividing them for cooking is then unavoidable. For quality, too, they cannot be surpassed, and when one has to cater for a gentleman's table quality is not to be lightly thought of.

To produce really good heads the plants need liberal treatment from the commencement. Therefore the ground chosen for them must have a dressing of well-decayed manure, and be dug to a good depth, taking care to bury the manure well under. A pinch of seed should be sown in a pan towards the end of January, and placed in a cool vinery, where it will germinate, and the plants soon be large enough to transfer singly into pots or dibbled into boxes.

We prefer the latter, as we find the plants are less likely to suffer by want of water. If pots are used care must be exercised at the time of planting in making sure that the ball of earth is thoroughly moist, otherwise should a dry period follow much difficulty may be experienced in preventing flagging, and we may be certain that if the plants receive a check in any way the result will be premature heads, or to use a gardener's term—buttoning will ensue. Keep the plants moving slowly and surely. Care should be taken that they receive no checks when being hardened previous to their being planted out on a south border. The beginning of April is the most suitable time for this, but even then it is necessary to have protection of some kind at hand in case of emergencies.

To follow the early Snowball, Magnum Bonum, King of Cauliflowers, and Autumn Mammoth, as well as Veitch's Autumn Giant, will extend the supply so long as they are safe from frost. If the soil is of a strong loamy character, containing much humus, the distance of 3 feet between the plants will be fully occupied by the two last mentioned varieties.

The seeds for succession should be sown early in February, and when the plants are large enough pricked off in boxes and placed in a gentle heat. A vinery just started will be found a suitable place for them until they become well established, when they will be best moved to cooler quarters. Air may be freely admitted, and on favourable days the lights be removed altogether. After choosing a good open position and weather permitting, plant out about the middle of April, and in case of drought water freely. For a further succession sow in March and April on a south border.—C. FOSTER.

THE PROPOSED VICTORIA MEDAL.

I DO not envy the Council of the Royal Horticultural Society the duty it will undertake presently in being called upon to find recipients for the proposed Victoria medal. I assume at the outset that these medals will be in number limited. That necessitates all the greater discrimination in making the selection of the recipients. Perhaps there may be twenty, perhaps fifty. We have in horticulture numbers of men in all its various aspects, some well known, some not so, who are well worthy of the highest honours that can be bestowed on their profession. Every one of those not selected will feel aggrieved. If the larger number mentioned (fifty) be distributed, then the proposed honour cannot be of great value. We are not even informed whether the medal is to be gold, silver, or bronze. Why cannot this be stated, and the principle on which the medals are to be awarded notified?

In no case would it be a medal earned by special work and as a well merited prize. In such cases one medal only is given, and no one else in the world has its duplicate. That is a real honour that may be prized. If the Council of the R.H.S. had proposed something worthy of the object, the celebration of the attainment by Her Majesty of a complete reign of sixty years, in which all its Fellows and the horticultural world at large could have shared, then many would have heartily assisted.

I know in inditing this deprecatory epistle I am not in harmony with the Editor's expressed views, but even the Journal Jupiter may now think there is something to be said on the other side. Specially, however, do I note that he has much warmer commendation for the Gardeners' Benevolent proposal, which is a noble and a generous one. That proposal is very easy to understand, and more in accord with Her Majesty's wishes than the suggested medal.—A FELLOW OF THE R.H.S.

[We have many times said that we have not the least objection to publish what is not in accordance with our own views, so long as the objections are temperately advanced. In this case our correspondent states there are "numbers of persons worthy of the highest honours," yet goes on to say that in "no case would the medal be earned by special work!" Have not the members of the Council of the R.H.S. and diligent coadjutors on committees done something for horticulture? Have not well-known representatives of provincial horticulture affiliated with the Royal Horticultural Society done something? Is the Victoria medal "for valour" the less appreciated by men of war because there is more than one medal? Why, then, should men of peace, who have deserved distinction, regard lightly an honour which others deserve equally with themselves? It is to be expected that the Council of the R.H.S. has considered the question of appropriation, just the same as the Veitch Trustees consider to whom and for what the medals at their disposal are awarded. We have not the slightest hesitation in saying that in our belief our correspondent has done at least as much for the advancement of horticulture as have many of the recipients of those much-prized distinctions, and we are entitled to doubt if one were offered to our critical "Fellow" that he would raise any strong objection to its acceptance because others had been as worthy of it as himself. As to charitable institutions the "Journal Jupiter" will say this—namely, that he would like to see every recipient of the Victoria Medal for Horticulture give a guinea donation to the Gardeners' Royal Benevolent Institution, and if he had his way he would make that a condition of its bestowal, as a thank-offering that the Queen has been permitted to reign over us during the greatest period of the prosperity of our country. What does our "Fellow" say to that? Will he give a guinea if he gets a Victoria medal?]

SOLANUM MACROCARPUM.—For greenhouse decoration in winter this Solanum is certainly an acquisition. To grow it well seeds should be sown in February, and the young plants kept growing without a check until they are placed in their fruiting pots about the end of May. At the last potting, pots 7 inches in diameter should be used, and a compost such as is generally adopted for Chrysanthemums. After potting the plants should be stood outside and treated in a similar manner to Chrysanthemums. They will then make plants about 1½ or 2 feet in height by the same in diameter, each plant having five or six branches thickly covered with spines, and producing leaves 6 to 8 inches long by 3 in width. Flowering takes place in August, and on an average twenty to twenty-five fruits are set on each plant. When mature the fruits are from 3 to 4 inches in circumference, red in colour, resembling in shape small smooth-skinned Tomatoes. The fruits ripen about the end of September, and remain in good condition about four months, long after the leaves have fallen. The plants should be housed about the middle of September.—W. D.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of this Society was held on Monday evening last at Anderton's Hotel, Fleet Street, when Mr. B. Wynne occupied the chair.

The minutes of the former meeting having been confirmed a question was asked concerning the definite fixture of the shows for 1897, and the Secretary replied that they would be as follows:—7th, 8th, and 9th September; 12th, 13th, and 14th October; 9th, 10th, and 11th November; and 7th, 8th, and 9th December. Notice of motion was given by Mr. Harman Payne to rescind the resolution to hold the Floral Committee meetings so late as three o'clock in the afternoon during the coming season. The same gentleman handed over to the Chairman the silver-gilt medal and diploma awarded to the N.C.S. for its exhibit of cut Chrysanthemums at the Ghent Show last November. A resolution was passed that the medal be photographed and a copy presented to every member who supplied blooms for this interesting exhibit; Mr. T. Bevan, the Chairman of the Floral Committee, to whom the credit of the exhibit was due, undertaking to distribute the photographs.

A vote was passed expressing the loss the Society had sustained in the death of Mr. W. Piercy of Forest Hill, the eminent specialist in early Chrysanthemums. During the present year the meetings of the General Committee will take place on 23rd August, 20th September, 25th October, 22nd November, and 13th December. The Floral Committee meetings will be held on 7th and 20th September; 12th and 25th October; 1st, 15th, 22nd, and 29th November; 7th and 13th December.

Of considerable interest was the reading of the report of the Committee specially appointed to discuss the classification of various disputed varieties. Among their decisions the following varieties will henceforth be classed as incurved proper—viz., Duchess of Fife, Golden Nugget, King of Orange, Ma Perfection, Miss L. D. Black, Miss Violet Foster, Miss Airdrie, The Egyptian, Triomphe d'Éve, and several more. This report will be printed for insertion in the new schedule, and will form an official supplement to the new catalogue. A vote of thanks was passed to the members of the Committee for their work, which was regarded with uniform satisfaction.

The Judges for the September, October, November, and December shows were appointed; those for the first named being Messrs. Rowbotham and G. Stevens; for October, Messrs. McHattie and J. Wright (Temple). The November show awards will be made by the following:—Plants, Messrs. Lyne and Prickett; incurved, Messrs. Moorman and C. Orchard; Japanese, Messrs. Geo. Gordon, C. Gibson, E. Beckett, and E. Molyneux; fruit, Messrs. Tegg and Reynolds; table decorations, Messrs. Wills and Wm. Marshall.

For their services to the Society Messrs. B. Wynne and T. W. Sanders were awarded silver-gilt medals, and Messrs. R. Ballantine, T. Bevan, and Williams bronze medals, all of the special Jubilee type. New members were elected, including Mr. H. de Vilmorin and Mr. H. Martinet of Paris, and the Dorking Chrysanthemum Society was admitted in affiliation.

CLASSIFICATION OF CHRYSANTHEMUMS.

ON page 5 of the Journal Mr. Molyneux brings into notice the old variety J. H. Runchman, stating that when properly cultivated it would be admissible in the incurved section. Undoubtedly it would prove a grand addition. There is yet another variety in Mons. Norman Davis, sent out by Mons. E. Calvat, but was classed by the Floral Committee as a Japanese incurved. After growing it I thought it one of the most charming incurved ever raised, and when staged by Messrs. Drover of Fareham in their winning stand of twelve incurved at the N.C.S. show in December the blooms were the most perfect in the exhibition. The colour was most pleasing, inside of the petals crimson, reverse old gold, without any sign of Japanese form whatever, forming a compact ball. There are many now on the market that lack such form sent out as incurved, and I with other growers would be very grateful for information from some of the N.C.S. Catalogue Committee regarding such varieties as Ma Perfection, Perle Dauphinoise, Duchess of Fife, Mons. Mailfai, and Miss P. Fowler.

J. S. Dibben, Creole, and Mrs. Smart have given me perfect incurved blooms on the terminal bud. Would these, with J. H. Runchman, be admissible in the incurved section?

The Egyptian, also on a late crown, has produced grand flowers with me, and quite equal in form to the old variety, Mrs. G. Rundle. I take the last named as a standard variety of form that our incurved should follow as nearly as possible. L'Améthiste and Percy Surman seem to me doubtful. The former I saw during the past season in two winning stands, one competitor staging it as an incurved, and the other as a Japanese. Percy Surman has been staged similarly at some of our largest exhibitions. Is it not time that such varieties as these were classed either as one or the other? If not I shall expect to see Modesto, and even George Savage or Olive Oclee, staged as incurved from late buds, they would make good back-row flowers in many stands.—W. G. ADAMS.

CHRYSANTHEMUM SPORTS.

MR. HENSLOW will be greatly obliged to cultivators of the Chrysanthemum if they will kindly inform him of any sports which they have had during the last two or three seasons, and to state the name of the parent plant as well as the colours of the flowers of both parent and sport; also to describe any special treatment the parents may have had. If they can suggest any other cause of the sport he will be glad to know of it.—*Drayton House, Ealing, London, W.*

A CHRYSANTHEMUM FREAK.

A FEW days ago, when going through the gardens at Nuneham Park, where a good collection of Chrysanthemums forms a striking feature throughout their season of flowering, Mr. Nichols, the head gardener, drew my attention to a very singular flowering sucker of the variety Louise.

From a plant grown in an 8-inch pot that had been cut down after flowering there emerged from the stem, about an inch below the surface of the soil, an adventitious slender leafless shoot, furnished, however, with a few diminutive bracts surmounted with a flower that would have as suitably crowned a season's normal growth. The length of the shoot is barely 5 inches, yet the diameter of the flower that it has produced, measuring beneath the extended ray florets, is over 6 inches, the whole appearing very much as though it had been cut from another plant and simply inserted in the soil.

A similar instance of so dwarf a sucker producing so large and as perfectly developed a flower has never before come under my notice. Through the kindness of Mr. Nichols I am enabled to send for your inspection the detached shoot (fig. 20) severed about half an inch from the stem that produced it. It may be of some interest.—JOHN E. JEFFERIES.

HIRSUTE OR HAIRY CHRYSANTHEMUMS.

MR. MOLYNEUX, in the last issue of the Journal, says this class does not seem to make much progress, which is quite correct; but this is not caused through lack of varieties, but rather by the growers. Very few care for these. Apparently the rage for size has much to do with their unpopularity, for all are deficient in this point, and in spite of all that has been said and written on the subject size is the chief point with present-day judges.

From one to two dozen novelties are introduced every season, but as they lack size they are discarded. This past season I have grown six new sports from Louis Boehmer, but all were dull coloured and shaded from pale yellow to orange and buff. These were introductions from Japan and California. Mr. Molyneux mentions whites. I would recommend him to try White Swan. It is about the size of Mrs. A. Hardy or larger; but it is a very full flower on any bud, and extremely hairy. Those who fancy this class will find this a gem. It is an introduction from California.—W. J. G., *Exmouth.*

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual meeting of this Society was held on the 20th inst. at the Museum, Orchard Street. There was a good attendance of members, who elected Mr. J. G. Newsham to the chair. The business of the meeting was to pass the accounts for the past season and to elect the officials for the current year. At the request of the Chairman the accounts to December 31st, 1896, which had previously been audited and passed, were read by the Secretary, Mr. W. Housley, which, after a few explanations, were unanimously passed.

The result of the past year's working was in a nice addition to the balance in hand brought forward from the previous year. This would have been considerably increased but for the heavy downfall of rain that occurred on the Saturday night of the show at a time when the visitors are most numerous.

The result of the election of officers is that most of the old members retain their seats. A vote of thanks to the Auditors, Messrs. J. Haigh and W. Redmill, for their services and to the Chairman terminated the proceedings.

ROOTING CARNATION CUTTINGS.

CARNATIONS are amongst the most popular flowers that we have at the present time, and the majority who possess glass accommodation are eager to cultivate them successfully. The inquiries how to root them by means of cuttings are numerous.

I remember some years ago rooting them very successfully by a system detailed by Mr. W. Taylor when at Longleat. It was something like this, to insert the cuttings in sandy soil in boxes 5 or 6 inches deep, and then cover them with glass after watering, the boxes being rendered air-tight by pasting strips of paper round the edges of the box. When these boxes were given slight bottom heat we found the cuttings rooted freely enough.

I cannot say I have been very successful in rooting Carnations by means of cuttings for some years past. This is mainly due to the want of a suitable place and the aid of bottom heat. Failure to root cuttings left us no alternative but to obtain plants by layering; certainly a safe and reliable method, but at times it takes up more room than can be well spared, especially at certain times of the year.

Not caring to be beaten in this matter we made an effort in another direction with successful results. First we tried a 10-inch pot half full of common sand, into which three small pots of Carnation cuttings were plunged, the pot being covered with glass, and then stood on a hot-

water pipe in a house where the temperature ranged from 60° to 65° at night. These cuttings rooted freely. Our plan is to fill boxes 1 foot or 15 inches deep partially with sand, cocoa-nut fibre refuse being preferred, so that long thumb pots can be partially plunged in and the top of the cuttings just clear of the glass.

The sand dries rapidly on the pipes, and must be made moist from time to time, or the soil about the cuttings becomes unduly dried. The cuttings selected are young growing shoots from plants in a cool or moderately cool house. Short growths are selected, in fact side growths broken out of the axils of the leaves of plants that are flowering or coming into flower. Sandy soil is used for the small pots, and four cuttings are inserted round the sides. It is not wise to crowd the cuttings, with some varieties three cuttings in each pot are better than four. After insertion the pots are watered, then they are ready for the boxes, and covering up with glass. After the cuttings are broken out of the axils of the leaves they are cut across with a sharp knife below

FIG. 20.—A CHRYSANTHEMUM FREAK (*much reduced*).

the first joint. So far we find very little difference whether they are cut below a joint, or the stem split up to the second joint.

After the pots are placed in the boxes no attempt is made to keep them air-tight. To do this would result in losing all the cuttings by damp. By keeping the sand or other plunging material moist in the boxes the cuttings would be constantly covered with moisture, and failure would result. We nearly failed by keeping them too close. The object should be to keep them as close as possible consistent with evaporating the moisture deposited upon them daily.

Our second venture in rooting on the hot-water pipes was 150 cuttings of Mrs. Leopold de Rothschild, which rooted in three weeks, 127 were potted singly, sixteen were again inserted, really losing only seven cuttings. We find some varieties root more freely and more quickly than others. Some commence rooting in a fortnight. If given three weeks the majority will root, and may within a month be potted singly. So far we have not resorted to shading the cuttings, at least only for a day or two after potting them singly if the sun comes out bright.—WM. BARDNEY, *Osmaston Manor.*

PERPETUAL SPINACH.—So far Winter Spinach has not felt the pinch of winter, but a good breadth of "Perpetual Spinach" and some cold frames for the plants will be useful should the weather prove severe through March, when it is a wise plan to take up some and place under cover. Oftentimes March winds kill more than frost. I have found the advantage of so doing, and shall lose no time in providing for an extra dish through March.—A. E.

WEATHER IN LONDON.—The frost that came last week is with us still, and shows little signs of departing. Several degrees have been registered each morning, and the prospects for metropolitan skaters are decidedly bright. Provided it is not too severe the frost will do a considerable amount of good.

WEATHER IN THE NORTH.—Frost of varying intensity has prevailed throughout the past week. On the 21st there were 9°, the same being recorded on Saturday morning. That day was an ideal winter one—bright, cold, and calm. On Sunday morning 11° frost were registered, but a thaw followed and continued throughout the day. Frost set in, and during the night nearly 2 inches of snow fell. Monday was keen throughout, with occasional snow showers. On Tuesday 14° of frost were indicated, with every appearance of its continuance.—B. D., *S. Perthshire*.

ROYAL BOTANIC SOCIETY.—At a meeting of the Fellows held in the Gardens, Regent's Park, on Saturday, the 23rd inst., Mr. J. S. Rubinstein brought forward a resolution recommending the Council to intimate to the Lord Mayor, the Chairmen of the London County Council, the London School Board, and other local authorities, and to the secretaries of recognised societies and institutions, that the Council would be pleased to arrange for the use in the coming season of the Society's Gardens for garden parties and receptions. The resolution was carried.

CHIONODOXA LUCILÆ.—I fear that Nature alone could give Mr. Arnott the information he asks for on page 27. Nature is capricious, and does not always disclose to us her secrets. I have little doubt, however, that the premature flowering of the "Glory of the Snow," in a garden within a mile of the Mull of Galloway, to which I alluded in a recent contribution, was owing not to the period when the bulbs were planted, but to the almost abnormal mildness of the season. During the last two months I have had lilac Primroses continuously in bloom. The St. Brigid Anemones are already preparing to flower, two months before their time. I anticipate, however, that they will not be permitted to proceed with their floral development, as within the last week frost has supervened, accompanied, providentially for early vegetation, with a gentle shower of snow—that white repentance of gracious Nature, whereby she mitigates her own severity.—D. R. WILLIAMSON.

VEITCH MEMORIAL FUND.—The Veitch Memorial Trustees have decided to present this year a large silver medal for distinguished service to horticulture to each of the following gentlemen:—To Norman C. Cookson, Esq., of Oakwood, Wylam-on-Tyne, for his successful hybridisation of Orchids, extending over many years, by which a large number of new and beautiful forms have been added to this remarkable family of plants. To Martin R. Smith, Esq., of Warren House, Hayes, an eminent amateur, who has been most successful in the raising of Carnations. By his efforts many new and beautiful varieties have been raised, especially in the Malmaison section, and among those which, on account of their hardihood and beauty, are adapted for culture in the open border. To Professor L. H. Bailey of Cornell University, Ithaca, N.Y., in recognition of his efforts, by means of his lectures and his writings, to place the cultivation of plants on a scientific basis; to promote the extension of horticultural education, and, by numerous trials and experiments, to improve and render more productive plants grown for economic purposes. To Mons. Charles Naudin of Antibes, a distinguished French botanist and horticulturist, who, by his prolonged series of experiments and observations, has much advanced the theory and practice of hybridisation. M. Naudin has also been highly successful in introducing, cultivating, and distributing a large number of plants of great economic importance, and of thus enhancing the resources not only of his own but of other countries. To Herr Max Leichtlin of Baden-Baden, as one who has rendered eminent service to horticulture by the introduction of a large number of interesting plants, and who has displayed equal sagacity and skill in their cultivation. The Trustees have also decided upon placing a medal and prize of £5 at the disposal of the Shropshire Horticultural Society, to be competed for at their Great Commemorative Exhibition in August next; and have allotted a similar medal and prize of £5 to the Trentham Horticultural Society.

DEATH OF MR. W. PIERCY.—It is with regret we have to record the death of Mr. W. Piercy of Forest Hill, who has done so much to advance the cultivation of early flowering Chrysanthemums. The deceased was born June 27th, 1825, and spent most of his early life in Islington.

LIVERPOOL HORTICULTURAL ASSOCIATION.—On Saturday evening the fourth meeting of the season was held in the Free Library, William Brown Street, Liverpool, Mr. T. White in the chair. The lecturer was Mr. J. Hathaway, Superintendent of Hesketh Park, Southport, formerly of Lathom House, the title of the paper being "Vegetables." As was to be expected from such a notable grower and exhibitor, the subject was dealt with in an excellent manner. The preparation of various soils, with corresponding cultural notes, were fully treated. Manures also formed an important part of the paper, and Mr. Hathaway soon led his audience to the conclusion that he was a firm believer in artificial manures, many of which were quoted. A discussion ensued, the meeting terminating with hearty votes to Lecturer and Chairman.

THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—An extra meeting of the above Society was held on Tuesday, January 19th, Mr. Chas. Lawton in the chair, when a paper on "Herbaceous and Alpine Plants" was read by Mr. A. J. Keeling, Bradford. The essayist must have had considerable practical experience with the subjects of his lecture by the masterly manner in which he handled it. This branch of the profession every gardener should be well acquainted with, some employers thinking as much of their hardy flowers as others do of their Orchids, and indeed it requires as much skill and knowledge to successfully cultivate them as it does the majority of Orchids. Mr. Keeling entered into all the details of their cultivation, their arrangement, and selection of varieties best adapted for the various soils. The weather proving unfavourable, members from a distance were unfortunately debarred the treat their more fortunate brethren enjoyed so much.—F. L. T.

GOLD MEDALLISTS OF THE FRUITERERS' COMPANY.—The banquet of the Worshipful Company of Fruiterers was held on Monday evening the 26th (St. Paul's Day), the newly elected Master, Thomas Platt, Esq., presiding, supported by the Lord Mayor and Sheriffs of London. About eighty members of the Livery and visitors attended. The banquet, speeches and music were of a very high order. The only horticultural Livermen present were Messrs. G. Bunyard and J. Wright. An interesting feature of the proceedings was the presentation of the large gold medals of the Company to Major W. Bythway and Mr. G. Bunyard for their magnificent collections of fruit at the Royal Horticultural Society's Show at the Crystal Palace last autumn. The Major made an earnest and excellent speech on the subject of fruit growing, and subsequently stated that he was mainly indebted for his success to an essay produced under the auspices of the Fruiterers' Company a few years ago, and which has passed through several editions.

THE SNOW.—The earth over a large portion of the kingdom is at present thickly covered with snow. It has come at a very convenient time of the year, when it gives to us who garden a minimum of inconvenience, yet it is a visitation that never seems welcome except to children, because it invariably hinders labour on the land. Our labour conditions here differ so much from those which exist in northern countries, where severe frost and snow annually prevailing over a large portion of the winter season, life and work are accommodated to those conditions. With us any appreciable hindrance to work not only soon produces inconvenience, but also much suffering. That is specially so in relation to soil cultivation. Much as we may rejoice to see vegetation only moderately hardy protected, if but for a short time, from injury by frost and biting wind, yet that same snow protection shuts us out from working the soil, or being upon it, and thus becomes a source of trouble. In addition it creates vegetable scarcity, and humanity and animals alike suffer. But whilst we credit the snow with saving our vegetable and corn crops from harm whilst it lies, we must not forget that the snow is with us at any time but a temporary visitation, and that this same vegetable life is exposed to all the harmful forces of frost and wind over much the greater period of the winter. Hence the approval usually given to a snow visitation is not always deserved. All gardeners know that shut out from other food supplies birds begin to prey upon fruit tree and bush buds voraciously, and do immense mischief, from which the snow does not save our fruits, indeed is the chief cause of the mischief. After all, here in England, at least, there seems to be good reason to doubt the tradition that winter snows are useful for vegetable protection.—A.

— THE WEATHER has been of a very wintery character during the past week. Friday was very stormy, with blinding snowstorms during the greater part of the day, and at night accompanied with heavy thunder and vivid flashes of lightning. The snow is very much drifted in places, 3 to 4 feet deep, but the average depth was about 6 inches, making locomotion very tedious and difficult, consequently all gardening operations are practically at a standstill in this neighbourhood.—G. R. ALLIS, *Old Warden Park, Beds.*

— THE WEATHER—SUMMARY FOR THE YEAR, 1896.—This was remarkable for a small rainfall and high temperature during the first five months, and a heavy rainfall with deficiency of sunshine during September, October, and December. The total rainfall was 2.63 inches below the average, although the month of September gave 1.83 inch above the average for the month, and was the wettest September since 1883. The prevailing direction of the wind was W. on 118 days. Total rainfall 24.46 inches, which fell on 202 days, the greatest daily fall being 0.89 inch on July 7th. Barometer—Highest reading, 30.698 on January 9th at noon; lowest, 28.454 on March 4th at 9 A.M. Thermometers—Highest in shade, 86°, June 16th and July 21st; lowest, 16°, February 26th. Mean of daily maxima, 55.82°; mean of daily minima, 41.14°. Mean temperature of the year, 48.48°; lowest on grass, 9° on February 26th; highest in sun, 145°, June 16th. Mean of earth at 3 feet, 49.25°. Total sunshine, 1409 hours 20 minutes; we had seventy-nine sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

— GARDENING SCHOLARSHIPS.—Mr. N. N. Sherwood, the Master of the Worshipful Company of Gardeners, has offered a scholarship of £25 a year for two years, to be awarded after the examination of the Royal Horticultural Society on April 6th, 1897, to the student that shall pass highest, if he is willing to accept the conditions attaching thereto. The main outline of these conditions is that the holder must be between the ages of eighteen and twenty-two years, and that he will study gardening for one year at least at the R.H.S. Gardens at Chiswick, conforming to the general rules laid down there for students. In the second year of the scholarship he may, if he like, continue his studies at some other place at home or abroad which shall be approved by the Gardeners' Company and by the R.H.S. Council. A similar scholarship has been kindly promised for 1898-9 by Mr. G. W. Burrows. If the student who is at the head of the examination is for any reason unable or unwilling to accept the scholarship, it is then offered to the next highest on the list, and so on throughout the first class.—(*"Gardeners' Magazine."*)

— ROYAL METEOROLOGICAL SOCIETY.—The annual general meeting of this Society was held on Wednesday, the 20th inst., at the Institution of Civil Engineers, Great George Street, Westminster, Mr. E. Mawley, F.R.H.S., President, in the chair. The Secretary read the Report of the Council, which showed that the Society had made steady progress during the past year, there being an increase of seventeen in the number of Fellows. The President then delivered an address on "Shade Temperatures," in which he stated that of all meteorological observations there were none approaching in importance those made of the temperature of the air—generally known as "shade temperature." Indeed, the first question invariably asked in regard to almost any climate was as to its temperature. Mr. Mawley traced the history of the different methods of exposing thermometers since the time that regular observations of the weather had been made in this country. For many years open screens were most favoured by meteorologists, that devised by Mr. J. Glaisher, F.R.S., and the late Astronomer Royal (Sir G. B. Airy) being the pattern principally used. In 1864 Mr. T. Stevenson, C.E., invented an admirable form of closed screen with louvred sides, which was considered preferable to the open type of screen, and has now almost entirely superseded the Glaisher stand. In 1883 the Stevenson screen was considerably improved by a Committee of the Royal Meteorological Society. Mr. Mawley then described his own experiments at Croydon and Berkhamsted as regards this improved screen, known as the Royal Meteorological Society's pattern. He showed that the only two defects which had been attributed to this form of thermometer exposure were virtually non-existent, and therefore advised its general adoption both in this country and on the Continent. Mr. Mawley had recently made observations in the Stevenson screen, and also in the screens used in France and Germany, and the conclusion he had come to was that the results obtained in the Stevenson screen were not only the nearest to the true air temperatures, but also more likely to be strictly comparable with temperatures taken in a similar screen but with different surroundings elsewhere.

— LEE, LEWISHAM, AND BLACKHEATH HORTICULTURAL SOCIETY.—We gather from the report of this well-known suburban Society that special efforts will be made during this year of Her Majesty's Diamond Jubilee to produce an exhibition worthy of the occasion. The winter session, it is said, is in full swing, and judging from the tone of the meetings and the excellence of the papers read it is expected to prove one of the most successful the Society has yet held.

— BARNESLEY PAXTON SOCIETY.—The thirteenth annual meeting of the Barnesley Paxton Society was held on Tuesday last the 19th inst. Mr. John Henshall, superintendent of Locke Park, occupying the chair. The report and balance-sheet as read by the Secretary, Mr. S. Balanger, showed the Society to be in a sound and flourishing state. During the past year twenty-six meetings had been held, devoted to the discussion of the most important current gardening subjects. The attendance showed a high percentage, and the Committee had every reason to be gratified by the interest in the papers read, the sound, practical, and genuine participation in the discussions by the members. The library had been augmented, and they might claim to have spent the money voted for that purpose, about £5, in a judicious manner. They had still a substantial balance in hand, and taking everything into due consideration they might fairly claim the past year the most successful one in the Society's career of thirteen years' duration. Mr. Henshall was re-elected as President; Messrs. Geo. Wright, J. Parker-Reeves, and Battey Vice-Presidents; Mr. W. Hoey, Treasurer; Mr. Hancock, Librarian; Mr. Winter, Curator; Messrs. Wilkinson and Rideau, Auditors.—T. G.

— A CLAIM FOR PRUNING FRUIT TREES.—At the Hereford County Court on Tuesday in last week, before his Honour Judge Harris Lea, Mr. John Watkins, Pomona Farm, Withington, sued Mr. Chas. Davies Andrews, solicitor, of Leominster, for £3 6s., balance of account as follows:—May, 1896, to pruning trees at Leysters Farm, men's time, and expenses, £26 6s. 6d.; by cash, £23 0s. 6d.; balance, £3 6s. In August, 1893, the plaintiff, at the request of Mr. Andrews, made an inspection of the trees to see what would be required in the way of pruning. In November, 1895, Mr. Andrews wrote to Mr. Watkins asking him to recommend a man to him whom he could rely on to do the pruning in the orchard he had walked over. Mr. Watkins, in accordance with that letter, recommended a man named Parry, who bore the reputation of being a skilful and experienced man. Mr. Andrews, in defence, contended that the work was not properly done. His Honour remarked that if Mr. Watkins had undertaken the work at a stated rate he would have been responsible for the proper carrying out of the work. But that was not the case. Having referred to some of the letters which had been read, he thought Mr. Watkins did all he could for the defendant. If he had made a contract it would have been a different thing. He gave judgment for plaintiff.

FLORISTS' FLOWERS AT HIGHBURY.

VARIOUS winter flowering plants for cut flowers and decorative purposes are extensively grown at Highbury, the well kept establishment of the Right Hon. J. Chamberlain. At a visit made just before Christmas the splendid conservatory was very gay with well grown Chrysanthemums of all the leading varieties beautifully arranged. Other flowering plants, such as Primulas, Begonias, Cyclamens, Zonal Pelargoniums, were all admirably represented, making with various foliage plants a fine display.

Well grown Primulas occupy one house, another being devoted entirely to Cyclamen. This is a grand sight, hundreds of plants showing large quantities of their beautiful varied coloured flowers. Sutton's Butterfly is one of the very best whites. Carnations continue to give their useful sweet-scented flowers for cutting purposes. Roses are breaking well, and the earliest are showing a grand crop of buds, which will prove most useful later on. Violets are extensively grown, and frames full of these are flowering most profusely. Stove flowering plants include fine Anthuriums, and Poinsettias have their place of welcome, the scarlet bracts showing well, intermixed with Palms and other foliage plants. These are only a few things I noted in a hurried run through with Mr. J. Deacon on a gloomy December day.

I noticed in the Orchid house some fine examples of *Cattleya labiata*, maxima, Dowiana; *Lælia* vars., *Dendrobiums*, *Odontoglossums*, *Oncidiums*, and many other well-grown Orchids. Speaking of *Dendrobies*, I measured a growth of *Wardianum* over 4 feet long, thick, and well-proportioned, showing flowers the whole length. As these are grown in great quantities, they must produce a grand display. The various *Lælias*, aniceps and all the varieties, are showing well; many dozens of spikes look most promising. These under the fostering care of Mr. Burberry, the Orchid grower here, will give a good account of themselves in the near future.—URBANUS.

CHEMISTRY IN THE GARDEN.

(Continued from page 48.)

NITROGEN (symbol N).—This element, like the two preceding it, is a colourless invisible gas, found abundantly in Nature in a free and also combined state. Free nitrogen forms nearly four-fifths of the atmosphere, and combined with other elements it is found in small quantities in the air and in water, and in larger quantities in soils, plants, and animals. Nitrogen is an essential constituent of all plants; it enters into the composition of protoplasm and other organic compounds found in them, protoplasm being the substance which is the living part of plants.

All the combined nitrogen on the earth has undoubtedly been derived from the free gas of the atmosphere. The free nitrogen, although present in such large quantities in the air, is of no direct value to plants, for with a few exceptions they cannot assimilate it. After years of careful research and numerous experiments it has been found that crops depend, with the exception of the Leguminosæ, upon nitrogenous compounds in the soil for their supply of nitrogen, and that plants absorb it by means of their roots, chiefly in the form of nitrates; but they may to a lesser extent also absorb it as ammonium salts. When we purchase nitrogenous manures we have to pay from 6d. to 9d. a pound for nitrogen in the form of ammonia, and from 9d. to 1s. for nitrogen in the form of nitrates. Seeing, therefore, how important ammonia and nitrates are from a commercial point of view, we should do well to devote a little of our time to their study.

AMMONIA (symbol NH_3).—This substance at ordinary temperatures is a gas possessed of a pungent odour, having an alkaline reaction. Ammonia, as we may see by its chemical formula, consists of one volume of nitrogen chemically united with three volumes of hydrogen. If equal volumes of hydrogen and nitrogen were weighed we should find that the latter would weigh fourteen times heavier than the former. In ammonia we have one volume of nitrogen which equals 14, and three volumes of hydrogen which equals 3; the weight of ammonia gas would therefore be seventeen times heavier than hydrogen gas, equal volumes being taken. As these varying weights may be a little puzzling to some of our readers it will, perhaps, be advisable before proceeding further to give a table of the elements we shall have to consider, with their respective weights appended.

APPROXIMATE WEIGHTS OF ELEMENTS.

Elements.	Weight.	Elements.	Weight.
Hydrogen	1	Potassium	39
Oxygen	16	Magnesium	24
Nitrogen	14	Calcium	40
Carbon	12	Iron	56
Sulphur	32	Chlorine	35½
Phosphorus	31	Sodium	23

Ammonia being a gas the gardener could not apply it very well in that form to his plants; but seeing it has an alkaline property, it will, therefore, combine with acids to form salts. These salts are solid substances, of which the following may be taken as examples:—Ammonium sulphate, ammonium nitrate, and ammonium phosphate.

Nitrates are salts formed by the chemical union of nitric acid (HNO_3) with a base. The alkaline bases, such as potash, soda, lime and magnesia, will all unite readily with nitric acid to form nitrates of potash, soda, lime, and magnesia, and these substances are of considerable value to gardeners as fertilisers. Ammonia and nitrates, however, will be dealt with more fully when we come to consider soils and manures in their relation to plant life.

CARBON (symbol C).—This substance is the most widely diffused in Nature of all the elements. It is found in a solid form, and nearly pure, in the diamond, in graphite, and in charcoal. It is also found in large quantities in a more impure state in coal. One hundred pounds of good anthracite from South Wales contains 92·73 lbs. of carbon, 3·36 lbs. of hydrogen, and 3·91 lbs. of oxygen and nitrogen. Carbon and oxygen unite chemically to form a gas called carbonic acid gas (CO_2). This acid combines readily with the base lime to form carbonate of lime or chalk, a substance which occurs in considerable quantities on the earth. On an average every 10,000 volumes of air contains four volumes of carbonic acid gas.

All parts of plants, and every organic compound found in them contains carbon. Plants obtain their carbon from the carbonic acid gas of the atmosphere by means of their leaves; and submerged water plants obtain their carbon from the same gas which is dissolved in water.—W. D.

(To be continued.)

DEUTZIA LEMOINEI.

So popular are the several species and varieties of Deutzias, as well for flowering in the open as for forcing for winter decoration, that a new one is hailed with pleasure. Several months ago a Deutzia named Lemoinei was staged at the Drill Hall by Messrs. Cripps & Son, Tunbridge Wells, and to which the Floral Committee adjudged a first-class certificate. In habit the plant is excellent, being dwarf and remarkably floriferous. In style of growth it favours Deutzia gracilis in many points, but the snow white flowers are produced on stout perpendicular growths differing from the well-known pendent habit of the older variety. The woodcut (fig. 21) will convey an idea of the form and manner of flowering of this beautiful plant.

THE DISCOLOURATION OF POTATOES.

HAVING read with much interest the instructive dissertations given by the various authorities at the recent Potato Tercentenary Conference, I failed to find particular mention of that all-important affection which unfortunately still reigns paramount throughout the kingdom, if not in other parts of the Potato-producing world. I allude to that detrimental ailment—the propensity of acquiring a discolouration in the tissues of the tuber when grown in certain soils (assuming that the nature of the soil to be the cause), owing presumably to a deficiency of some constituent necessary for the production of good and mealy Potatoes free from the blemish indicated, and which, next to the “disease,” is one of the most undesirable affections to which the “noble tuber” is heir.

Various theories have been advanced as to the real cause and nature of the ailment in question, and in addition to that pertaining to some chemical constituent deficiency in the soil. The more general theory entertained amongst cultivators, such as farmers and market gardeners, is that founded upon the supposition that it is the effect of bruising the tubers through rough handling when gathering and storing the crop. Another theory is entertained that it arises from a superheating of the tubers when stored in large heaps for the winter, and with insufficient ventilation or other provision for the escape of the steam.

Obviously, however, such theories can hardly be sustained, considering that the ailment in question affects the tubers whilst in their growing state, yet it may be more developed by the storing agency, but hardly by bruising from rough handling. Moreover, there is a factor I have noticed in particular appertaining to the discolouration indicated, and which I opine reaches so far as to discount the storing and bruising theories; it is to the effect that the ailment is confined chiefly to the base of the tuber, or the end opposite to that attached to the roots of the plant—at least, such is the initial position of the affection—and whence it gradually spreads throughout the economy of the tuber according to circumstances.

This theory may be speculative, however, and is subject to further proof, unless some scientist or keener observer than myself is already enabled to confirm or repudiate it, and I for one would be glad to learn if something more definite than that herein advanced can be adduced as to the real cause and nature of the matter in question. I forgot to mention that an excess of humus or nitrogenous pabulum in the soil has been suggested as a probable agent in the production of the ailment.

In conclusion I may remark that during the present winter I have procured samples of Potatoes from several growers and districts supplying the Birmingham market by way of a test, and have found the majority of the samples more or less affected by the phenomenon—the subject of the foregoing remarks.—W. G.

HEPATICAS.

THE common Hepatica in its several varieties has been an admired denizen of gardens for a long period. Parkinson describes no less than ten sorts, of which some at least are still in cultivation. They were known also as Liverworts, under the botanical appellation of Hepatica trifolia, the specific name after a time being superseded by the more correct “triloba.” The latter designation was changed by Linnaeus, by whom the plant was renamed Anemone hepatica; but this appears to have been received with little favour by gardening writers, and even now few recognise the plant under that name. In the “Paradise” three white varieties are described—“the lesser white,” which I take to be “nivea” of Loudon; “the great white,” and “the white with red threads,” which is Loudon’s “red-anthered white,” or alba. The last named is the sort generally sold by nurserymen for the single white. This with the other two I have grown for many years. There are also three blue varieties mentioned. One of these is “blew tending to violet purple.” Parkinson’s red Hepatica is “of a bright blush, or pale red colour, very pleasant to behold, with white threads or chives (anthers) in the middle of them.”

Another variety is “the ash-coloured or argentrive,” notice of which I have found nowhere else. The flowers are much larger than those of the others. I have two varieties of H. angulosa, which are in respect of habit, size of foliage, and flower distinct from each other, though similar in colour. Is it not possible that one of these may be the argentrive? Of double varieties only two are named, both of which are still cultivated.

One is the double purple, now sold as "*coerulea fl.-pl.*" "The flowers are small buttons, but very thick of leaves and as double as a flower can be, of a deep blue or purple colour." This variety is weakly in constitution; a plant I have had for at least twenty years is no whit larger now than it was when planted. The other is the double blue Hepatica, a variety that is identical in the shape of the flowers with the double red, and of which a bloom is portrayed with great exactness in Hill's "*Eden.*" Rea calls it "watchet blue." This writer describes the double white Hepatica, which, he says, has "smaller and fresher green leaves than the others; the flowers snow white and as thick and double."

This variety, said by the writer to be "the most rare and tender," as well as a single white, double and single blue, and double and single red, is mentioned by Laurence in "*A New System of Husbandry,*" 1727,

Barlowi is well known. I grow, besides those already noted, a light coral coloured variety, and another with deep pink flowers, both very pretty. Robinson, in "*Alpine Flowers,*" mentions *splendens*, and one grower catalogues *violacea*, both varieties that I have not seen.

The finest of all Hepaticas, however, is the large-flowered form of *angulosa*. It spreads over the surface of the ground, and in a few years forms broad masses which are perfectly smothered in late spring with large flowers of a lovely light blue colour. No kind grows so well as this, and judged on its merits it is doubtful if any flower blooming at the same time surpasses it in quiet beauty.

Hepaticas are generally supposed to be easy to cultivate, but on light soils I have found them, with the exception of a few varieties, to be rather difficult to manage. In a state of nature they choose a somewhat shady position. Under cultivation they appear to require a strong

FIG. 21.—*DEUTZIA LEMOINEI*.

Laurence says there are other kinds, but those he mentions are considered to be most worthy cultivation. He includes Hepaticas and all other low-growing plants under the curious appellation of "reptiles," which he explains is because they grow near the ground. It is to be remarked that in the part of the work devoted to horticulture, which is a very small portion of the whole, matters are noted that go to show Laurence cannot be credited as an authority. Hence, when we find in Hill's "*Eden*" (1757) a shade of suspicion hovering over the existence of the double white Hepatica one is more careful in giving credence to what the other writes about it. Though Hill is said not to have written himself, his book bears evidence that it was written by someone well up in the subject.

In addition to these I have a note that Crispin de Pass names and figures a yellow variety—"H. trifolia aureum." This, the double white and the argentea, would be welcome additions could they be found to the number of our old flowers. Of what may be called modern varieties

holding soil, and a position somewhat shaded from the sun. In herbaceous border running north and south they exhibit a marked preference for the west side of the walk. An established plant resents removal or division, therefore it is well, a short time previous to the appearance of the flowers, that a little fresh soil be sprinkled over the clumps. This has a markedly beneficial effect on their health.

The plants bear seed very freely, and old writers advise advantage to be taken of this in order to raise new colours; and, if the seeds are kept for some years before sowing, new double varieties. Seedlings come up plentifully here, but no new variety has been produced. I have seen the practice of raising plants from seeds recommended of recent years. It would be interesting to know from some one of those who have raised seedling Hepaticas what they think of the plan, and whether any variety of outstanding merit has been produced. None of our seedsmen offers seeds, and one is induced to believe that the practice has never taken hold.—R. P. B.

ROYAL HORTICULTURAL SOCIETY.

THE COMMITTEES FOR 1897.

IN a recent issue we gave the dates of the meetings of this Society, to be held during the ensuing year. Full particulars of the exhibitions can be had from the Society's publication, known as "Arrangements for 1897," in which are also given lists of the various Committees, and these we reprint for the benefit of our readers.

SCIENTIFIC COMMITTEE.

Chairman.—Sir J. D. Hooker, K.C.S.I., C.B., F.R.S., &c., The Camp, Sunningdale.

Vice-Chairmen.—Dyer, W. T. Thiselton, C.M.G., F.R.S., Royal Gardens, Kew; Foster, Prof. M., Sec. R.S., Great Shelford, Cambridge; Masters, Maxwell T., M.D., F.R.S., &c., Mount Avenue, Ealing, W.

Hon. Secretary.—Rev. Prof. G. Henslow, M.A., F.L.S., Drayton House, Ealing, W.

Allen, J., Park House, Shepton Mallet.
Baker, J. G., F.R.S., Royal Gardens, Kew.
Balfour, Prof. I. B., F.R.S., Botanic Gardens, Edinburgh.
Bonavia, Dr. E., 5, Harrington Mansions, South Kensington.
Burbidge, F. W., M.A., F.L.S., Trinity College Gardens, Dublin.
Church, Prof. A. H., M.A., F.R.S., Shelsley, Kew Gardens.
Clarke, Col. R. Trevor, Welton Place, Daventry.
Darwin, Francis, F.R.S., Wychfield, Huntingdon Road, Cambridge.
Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire.
Elwes, H. J., F.L.S., F.Z.S., Colesborne, Andoversford, Glos.
Engleheart, Rev. G. H., M.A., Appleshaw, Andover.
Farmer, Prof. J. B., M.A., Royal College of Science, S. Kensington.
Frankland, E., F.R.S., The Yews, Reigate Hill, Reigate.
Godman, F. DuCane, F.R.S., 10, Chandos Street, Cavendish Square.
Lindsay, R., Botanic Gardens, Edinburgh.
Llewelyn, Sir J. T. D., Bart., F.L.S., Penllergaer, Swansea.
Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.
Maxwell, W. H., Munches, Dalbeattie, N.B.
McLachlan, R., F.R.S., Westview, Clarendon Road, Lewisham, S.E.
Michael, A. D., F.L.S., Cadogan Mansions, Sloane Square, S.W.
Morris, D., C.M.G., M.A., F.L.S., D.Sc., 14, Cumberland Road, Kew.
Müller, Hugo, Ph.D., F.R.S., 13, Park Square East, Regent's Park.
Oliver, F. W., D.Sc., F.L.S., 10, Kew Gardens Road, Kew.
Plowright, C. B., F.L.S., 7, King Street, King's Lynn.
Russell, W. J., F.R.S., Ph.D., 34, Upper Hamilton Terrace, N.W.
Scott, D. H., M.A., Ph.D., F.R.S., F.L.S., The Old Palace, Richmond, S.W.
Sutton, A. W., F.L.S., Reading.
Veitch, H. J., F.L.S., King's Road, Chelsea, S.W.
Ward, Prof. Marshall, F.R.S., The Laurels, Englefield Green, Staines.
Wilson, Geo. F., F.R.S., Heatherbank, Weybridge Heath.

FRUIT AND VEGETABLE COMMITTEE.

Chairman.—Crowley, Philip, F.L.S., Waddon House, Croydon.

Vice-Chairmen.—Bunyard, Geo., The Royal Nurseries, Maidstone; Hogg, R., LL.D., F.L.S., 99, St. George's Road, S.W.; Rivers, T. Francis, Sawbridgeworth.

Secretary.—Wilks, Rev. W., Shirley Vicarage, Croydon.

Balderson, H., Corner Hall, Hemel Hempstead.
Barron, A. F., Sutton Court Road, Chiswick, W.
Bates, W., Poulett Lodge Gardens, Twickenham.
Bennett, W., Rangemore Park Gardens, Burton-on-Trent.
Cheal, Joseph, Crawley, Sussex.
Crasp, T. H., Osberton Hall Gardens, Worksop.
Crump, W., Madresfield Court Gardens, Malvern.
Cummins, G. W., The Grange Gardens, Wallington.
Dean, A., 62, Richmond Road, Kingston, S.W.
Divers, W. H., Belvoir Castle Gardens, Grantham.
Dunn, Malcolm, The Palace Gardens, Dalkeith, N.B.
Empson, W. J., Ampthill House Gardens, Beds.
Farr, W., Spring Grove House Gardens, Isleworth.
Fife, Robert, Dobbie's Nurseries, Orpington, Kent.
Herrin, C., Dropmore Gardens, Maidenhead.
Iggulden, W., North View, Frome, Somerset.
Laing, J., jun., Forest Hill, S.E.
Lane, Fred. Q., Berkhamsted.
McIndoe, James, Hutton Hall Gardens, Guisborough.
Miles, G. T., Wycomb Abbey, High Wycomb.
Norman, G., Hatfield House Gardens, Hatfield.
Pearson, A. H., The Nurseries, Chilwell, Notts.
Pope, W., Highclere Gardens, Newbury.
Reynolds, G., The Gardens, Gunnersbury Park, Acton.
Sage, G. H., Ham House Gardens, Richmond, S.W.
Saltmarsh, T. J., The Nurseries, Chelmsford.
Smith, James, The Gardens, Mentmore, Leighton Buzzard.
Veitch, J. H., King's Road, Chelsea.
Veitch, P. C. M., The Royal Nurseries, Exeter.
Ward, H. W., Lime House, Rayleigh, Essex.
Willard, Jesse, Holly Lodge Gardens, Highgate, N.
Woodward, G., Barham Court, Teston, Maidstone.
Wright, John, 171, Fleet Street.
Wythes, G., Syon House Gardens, Brentford.

FLORAL COMMITTEE.

Chairman.—Marshall, William, Auchinraith, Bexley.

Vice-Chairmen.—Fraser, John, The Nurseries, South Woodford Paul, George, The Old Nurseries, Cheshunt.

Secretary.—T. Humphreys, R.H.S. Gardens, Chiswick, W.

Bain, W., The Gardens, Burford Lodge, Dorking.

Barnes, N. F., Eaton Gardens, Chester.

Barr, W., 12, King Street, Covent Garden, W.C.

Beckett, E., Aldenham House Gardens, Elstree.

Blick, Chas., The Warren, Hayes Common, Beckenham.

Cannell, H., Swanley, Kent.

Crane, D. B., Archway Road, Highgate, N.

Catbush, H. J., The Nurseries, Highgate, N.

Dean, R., Ranelagh Road, Ealing, W.

Druery, C. T., F.L.S., 25, Windsor Road, Forest Gate.

Fitt, J. H., The Frythe Gardens, Welwyn.

Fraser, John, Willow Cottages, Kew.

Gordon, G., Endsleigh, Priory Park, Kew.

Herbst, H., Kew Road, Richmond, Surrey.

Hogg, R. M., 99, St. George's Road, Pimlico, S.W.

Hudson, J., Gunnersbury House, Acton.

Jeffries, C., Boston House Gardens, Brentford.

Jennings, J., Ascott Gardens, Leighton Buzzard.

Jones, H. J., Ryecroft, Hither Green, Lewisham.

Laing, J., Forest Hill, S.E.

Lowe, R. B., Ashridge Gardens, Berkhamsted.

McLeod, J., Dover House Gardens, Roehampton.

May, H. B., Dyson's Lane, Upper Edmonton.

Mawley, E., Rosebank, Berkhamsted.

Molyneux, E., Swanmore Park Gardens, Bishop's Waltham.

Nicholson, G., Royal Gardens, Kew.

Owen, R., Castle Hill, Maidenhead.

Pawle, J. D., 12, Stanley Gardens, Willesden Green, N.W.

Pearson, C. E., Chilwell, Nottingham.

Peed, T., Roupell Park, West Norwood.

Salter, C. J., Woodhatch Gardens, Reigate.

Sanders, T. W., 124, Embleton Road, Lewisham.

Selfe-Leonard, H., Hitherbury, Guildford.

Stevens, Geo., St. John's Nursery, Putney.

Thomas, Owen, Royal Gardens, Windsor.

Turner, H., Royal Nurseries, Slough.

Walker, J., Ham Common, Surrey.

ORCHID COMMITTEE.

Chairman.—Veitch, H. J., F.L.S., Royal Exotic Nursery, Chelsea, S.W.

Vice-Chairmen.—Courtauld, Sydney, Bocking Place, Braintree; Lawrence, Sir Trevor, Bart., 57, Princes Gate, S.W.; Schröder, Baron, The Dell, Staines.

Secretary.—O'Brien, James, West Street, Harrow-on-the-Hill.

Ashworth, E., Harefield Hall, Wilmslow, Cheshire.

Ballantine, H., The Dell Gardens, Staines.

Bogaerde, A. V., The Woodlands, Great Barr, Birmingham.

Bond, T. W., Elstead House Gardens, Godalming.

Brooman-White, R., Ardarroch, Garelochhead, N.B.

Broome, Joseph, Sunny Hill, Llandudno.

Burberry, H. A., Highbury Gardens, Birmingham.

Chapman, H., Cambridge Lodge, Flodden Road, Camberwell.

Cobb, W., Broadwater Down, Tunbridge Wells.

Cookson, Norman C., Oakwood, Wylam-on-Tyne.

Crawshaw, De Barri, Rosefield, Sevenoaks.

Fowler, J. Gurney, Glebeland, Woodford.

Gabriel, J. T., 32, Palace Road, Streatham Hill.

Handley, Rev. E., 19, Royal Crescent, Bath.

Hardy, Fred, Tyntesfield, Ashton-on-Mersey.

Hill, E., Tring Park Gardens, Tring.

Ingram, C., 86, Onslow Gardens, S.W.

Jacomb, F. C., Cheam Park, Surrey.

Jacques, J., Waddesdon Manor Gardens, Aylesbury.

Latham, W. B., Botanic Gardens, Edgbaston, Birmingham.

Law-Schofield, G. W., New Hall Hey, Rawtenstall, Manchester.

Mason, Major, The Firs, Warwick.

Pilcher, Charles, 84, Ringford Road, Wandsworth, S.W.

Pollett, H. M., Fernside, Bickley, Kent.

Protheroe, W. H., 67, Cheapside, E.C.

Sander, F., St. Albans.

Smee, A. H., Wallington, Surrey.

Thompson, W., Walton Grange, Stone, Staffs.

Thorne, F. J., The Gardens, Sunningdale Park.

Tod, D., Eastwood Park, Thornliebank, N.B.

Watson, W., Royal Gardens, Kew.

White, W. H., Burford Lodge Gardens, Dorking.

Williams, H., Victoria Nurseries, Holloway, N.

Winn, C., The Uplands, Selly Hill, near Birmingham.

Young, W. H., Clare Lawn Gardens, East Sheen, S.W.

NARCISSUS COMMITTEE.

Chairman.—Prof. M. Foster, Sec. R.S., Shelford, Cambridge.

Vice-Chairmen.—Baker, J. G., F.R.S., Royal Herbarium, Kew; Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire; Engleheart, Rev. George H., Appleshaw, Andover; Wilks, Rev. W., Shirley Vicarage, Croydon.

Secretary.—Scraser-Dickins, C. R., Coolhurst Park, Horsham.
 Barr, P., 12, King Street, Covent Garden, W.C.
 Bennett-Poë, John T., 29, Ashley Place, S.W.
 Bourne, Rev. S. E., Dunston Vicarage, Lincoln.
 Burbidge, F. W., M.A., Trinity College Gardens, Dublin.
 Cammell, G., Brookfield, Hathersage, near Sheffield.
 Cammell, M., Loxwood House, Billingshurst, Sussex.
 Cowan, C. W., Valleyfield, Penicuik, Midlothian.
 De Graaff, S. A., Leyden, Holland.
 Goldring, W., 34, Gloucester Road, Kew.
 Kingsmill, A., Esq., The Holt, Harrow Weald, Stanmore.
 Krelage, J. H., Haarlem, Holland.
 Leichtlin, Max, Baden-Baden.
 MacMichael, Rev. C., Walpole Rectory, Wisbech.
 Marsh, Rev. T. H., Cawston Rectory, Norfolk.
 Milne, Readhead, R., Holden Clough, Bolton-by-Bowland, Clitheroe.
 Moore, F. W., Royal Botanic Gardens, Glasnevin, Dublin.
 Perry, Amos I., Hardy Plant Farm, Winchmore Hill, N.
 Vilmorin, Henry L. De, Quai de la Mégisserie, Paris.
 Walker, James, Ham Common, Surrey.
 Ware, Walter T., Inglescombe Nurseries, near Bath.
 Willmott, Miss, Warley Place, Great Warley, Essex.

FERTILISERS FOR THE ORCHARD.

AT the recent annual meeting of the Indiana Horticultural Society a paper read by Mr. W. W. Stevens on the "Feeding and Care of Orchards" contained many valuable thoughts. As to the relation between fertility of soil of the best crops, he said that when a bearing orchard begins to decline in the quality of fruit lack of fertility is indicated. Orchards should be fed before the fertility is exhausted and the trees become stunted. It is a simple matter to understand that orchards must be fertilised for precisely the same reason that our grain fields and gardens are manured. The fruit removes the phosphoric acid, nitrogen and potash from the soil just the same as cereals and root crops do, and we must keep a liberal supply of available plant-food in the soil for the orchard if we expect profitable returns. In fact it is more necessary to fertilise the orchard than it is our grain fields, for the reason that on most farms much of the grain produced is consumed by the stock, and through the manure heap finds its way back to the land, while there is little or nothing that goes back to the soil from the fruit crop that is harvested year after year.

We hear the question asked quite frequently, Why is it that our orchards are not vigorous and long-lived as they used to be? It is chiefly because they are starved to death. Even the new lands we now clear up are not as rich in vegetable mould and the mineral elements of the plant food that make tree growth as they were half a century ago. In fact, much of our woodland is now pastured until it is half exhausted before the trees are taken off, or rather die off.

It requires about the same elements of plant food to make an Apple tree that it does a Pear or Peach, but when the fruits are analysed we find quite a difference in their composition. For example:

	Phos. acid.	Potash.	Nitrogen.
100 bushels Apples contain ...	1 lb.	10 lbs.	7 lbs.
100 bushels Pears, about ...	1½ lb.	4 lbs.	5 lbs.
100 bushels Peaches, about ...	2½ lbs.	13 lbs.	6 lbs.

Thus we see that potash is the predominating element in Apples and Peaches, while nitrogen leads in Pears. Apples need two and a half times and Peaches three times as much potash as Pears. It would not be good judgment to use precisely the quantities indicated in the above table to get an additional 100 bushels of fruit. The new wood-growth and foliage must be accounted for, as well as an allowance for some losses through fermentation and bleaching. It is also impracticable to distribute any fertiliser so perfectly as to bring all of it within reach of the feeding rootlets of a tree. I would always advise a liberal use of such plant food as we are sure our trees need, for a year lost in an orchard by failure to feed is gone irretrievably.

Whatever we use to fertilise the orchard should be in readily available form, so that the trees can profit from it from the moment it is worked into the soil. Barnyard manure is not the best thing to use by any means. Its nitrogen is partly available, but the potash and phosphoric acid are not. When barnyard manure is applied new wood will be formed in abundance, while the aim of the orchardist should be to have as little new wood as is consistent with bearing spurs, and these spurs will not form satisfactorily when there is too much nitrogen in the soil. Besides, fruit from orchards fed with improperly balanced manures not only keeps badly, but also lacks flavour.

The following formulas are suggested for bearing orchards:—For Apples, ammonia 4, potash 6, phosphoric acid 2 per cent. For Peaches, ammonia 4, potash 5, and phosphoric acid 6 per cent. For Pears, ammonia 4, potash 2, and phosphoric acid 4 per cent. Acidulated tankage is preferable for the ammonia, or fish scrap if more convenient. The cheapest potash would be the muriate. The phosphoric acid is most useful as acid phosphate. From 500 to 600 lbs. of fertiliser to the acre should be applied and worked well into the soil every year, whether the orchard bears or not.

When these available fertilisers are used the application should be made in early spring, and then there can be no loss of fertility during the winter from surface drainage or leaching. Clover can be grown and

ploughed under to supply the orchard with the nitrogen it needs, but the potash and phosphoric acid must be spread upon the land, having been obtained from whatever source is cheapest.

When orchards are on very rolling land, or land that washes badly, seed down to Clover and orchard grass and cultivate about the trees with the hoe for several years, or until they are old enough to bear. Such an orchard should never be pastured with any kind of stock, and the ground will remain loose and offer a nice mellow bed for the feeding rootlets of trees.

Mr. Stevens does not think it pays to renovate old orchards. The time and labour spent to get them into any sort of satisfactory condition will suffice to start a new orchard that will be a source of profit and satisfaction for half a lifetime.—J. TROOP (in "Garden and Forest.")

NOTES FROM THE ISLE OF WIGHT.

THE ARRETON HORTICULTURAL SOCIETY.

THE annual meeting of this Society was held on Wednesday, January 20th. The Rev. J. Black-Hyland was re-elected President, and Mr. G. Way, C.A., Chairman of Committee. The date of the next show was fixed for July 28th, 1897. Prizes were offered to be competed for at the next show by Messrs. Daniel & Son of Norwich, Toogood & Sons of Southampton, and John Dimmick of Ryde.

ISLE OF WIGHT CHRYSANTHEMUM SOCIETY.

The annual meeting of the Isle of Wight Chrysanthemum Society was held at Warburton's Hotel, Newport, on Saturday, January 16th. Dr. Groves, B.A., J.P., Chairman of the Society, presided. The financial statement showed that the year 1896 commenced with a surplus of £23 9s. 5d. The takings of the last show amounted to £30 7s. 5d., which, with donations, brought the total amount of receipts to £98 11s. 4d. The balance in hand for next show is £22 7s. Then followed the election of officers. Sir Chas. Seely was re-elected President, Dr. J. Groves Chairman, Dr. M. L. B. Coombs Treasurer, and Mr. J. Taplin Assistant Secretary. Mr. A. E. Cave resigned his position as Secretary, which office will no doubt be taken by Mr. C. H. Cave, florist and seedsman, Newport.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.

A special meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last, Dr. Groves in the chair. A unanimous vote of thanks was accorded Mr. C. L. Conacher, the new Manager of the Isle of Wight Central Railway, for the reductions he had made in the carriage of Island garden and farm produce, thereby assisting the above Association in promoting the development of the principal industries of the Island. A sub-committee was afterwards appointed to draw up a scheme for the re-organisation of the Association. It was also decided that the Association be affiliated with the R.H.S.

ISLE OF WIGHT COUNTY COUNCIL.

The quarterly meeting of the Isle of Wight County Council was held at the Guildhall, Newport, January 13th, 1897. The Technical Education Committee (Chairman, Col. Crozier, J.P.), reported that the organising Secretary (Prof. Custance) had informed them that during the three months ending December 25th, 1896, thirty-seven village classes had been conducted in the rural district, of which six were horticultural classes.

The horticultural classes had been held at Niton, Carisbrooke, Haven Street, Blackwater, Alverstoke, and Bembridge. The average attendance was good, especially at the Bembridge class. Lectures had been given by the Horticultural Instructor on the following subjects:—"Garden Insects," with lantern slides; "Bees and Bee-keeping," with lantern slides; "Cultivation of Peas and Beans;" "Seaweed, Bones, Soot, and Lime," their value as manures; "Varieties of Early and Late Potatoes for Light and Heavy Soils," with samples; "Canker Club-root, and Potato Blight," with diagrams.

THE YOUNG GARDENERS' DOMAIN.

EUCHARIS CULTURE.

WHAT can be more useful than the beautiful Eucharis Lily with its pure white flowers, and yet in many places we do not see the plants in a thriving condition. To grow them well a good bottom heat and a stove temperature are indispensable, and if a house can be devoted exclusively to their culture so much the better.

I think a common cause of failure is too frequent potting, as experience teaches me that they are very impatient of being disturbed. Most of the plants in the houses under my charge have not been potted for three years, and they are now the picture of health, some of them in 12-inch pots throwing as many as ten spikes of flowers.

When the flowering period is over we rest the plants about six or eight weeks, by lowering the temperature of the house a little. The syringe is used among them freely on bright days, and as the power of the sun increases a light shade is given them.

E. amazonica produces an abundance of bloom, and is very useful for making into wreaths. The smaller flowering variety, E. Stevensi, does not flower so freely with us as the first named, but is more suitable for bouquets and lighter floral work.

The mealy bug is a troublesome pest, but can readily be removed by

sponging the leaves with an insecticide, used according to the directions given by the vendors.

When packing the blooms for transit light shallow boxes should be used (16 inches by 10 inches and 2½ inches deep we find a convenient size), which ought to be neatly lined with tissue paper, and the flowers placed in rows across the box with layers of wadding between them. Thin twigs the exact width of the box pressed down across the ends of the stems as the packing proceeds keep the flowers in position, and thus reducing the liability of their getting bruised.—H. C.

CYCLAMEN.

At the present time we have in flower in these gardens about 100 plants of *Cyclamen persicum*, some of which are carrying between fifty and sixty blooms. The seed was sown on August 8th, 1895, in a temperature of 50°. The seedlings were potted on February 6th, 1896, in 2½-inch pots, and placed on a shelf near the glass. They were next shifted into 4½-inch, and eventually into their flowering pots on July 8th. The soil for each potting contained equal parts of loam, leaf soil, and sand, with about one-fifth of deer droppings. In June the plants were placed close to the glass in frames under a north wall, air being constantly admitted, and on favourable occasions the lights were taken off. Liquid manure was applied twice a week, and a slight syringing given three times a day. They are now flowering in a temperature of 45° to 50°.—F. R., *Nostell Priory Gardens*.

[Concise, precise, and very well written indeed.]

KEEPING A DIARY.

HAVING with pleasure read "Preserving the Best," by "H. T.," page 634 (last volume), in the "Young Gardeners' Domain," I think it a sensible way of preserving articles written by practical men on various subjects in connection with our calling. I therefore hope that many more will follow his plan, from which they will eventually derive much benefit. Keeping a diary consists in writing down each night the work done during the day; also in noting how fruit trees, vegetables, and plants may be progressing in their various stages, along with any experiments that may have been tried with artificial manures or insecticides, and recording their results. Through the kind advice of my superior I was advised to keep a diary for reference in days to come; by so doing I have been able to keep in store much valuable information which no doubt would have been lost. I hope that all young gardeners who have overlooked the great benefit to be derived by so doing will start at once. The most suitable diary I have found is Collins', 1s. each, interleaved with blotting, spaces marked off for each day.—J. W.

CULTURE OF HERBACEOUS CALCEOLARIAS.

SOME experience gained by the cultivation of these plants enables me to give a few details regarding their treatment. A well drained pan, thoroughly clean, nearly full of the following mixture—Loam (good), two parts, leaf mould, one part, coarse sand, one part.

The seed was sown about the middle of June, covered lightly, the pan being then placed on an inverted pot which was standing in another receptacle containing water to prevent slugs from injuring the seedlings, in a cold frame. As soon as large enough the seedlings were potted in 60's, using the same kind of soil as before; they were then placed on a shelf near the glass in the greenhouse. When the plants were ready for another size pot (48's) it was given them, using one-sixth part of old Mushroom bed refuse in addition to the soil mentioned above. Plants in this size pot proved very useful for vases, the others being grown in 32's.

A little stimulant, such as sheep manure water, helps them considerably, especially when throwing up their spikes. Use no more heat than is absolutely necessary; in fact, if the temperature is at freezing point it will not hurt the plants. Keep the surroundings moist, and shade a little when the sun is strong, or they will drop their foliage. Keep a sharp eye for slugs and green fly, and with careful attention you will see on the margins of the leaves drops of water, which is sufficient to say you can manage one of the best of our greenhouse flowering plants.—A. F. L.

TAKING CHRYSANTHEMUM CUTTINGS.

MUCH valuable time is lost and inconvenience caused when this work is not methodically done. On the return of the hulk of the plants from the conservatory the varieties should be arranged in rotation. This is time well spent. If the plants are numbered at potting time, allowing for those still in bloom, they are easily sorted even when a large number are grown.

Many advantages accrue from this simple method. The quantity of cuttings for each variety may readily be ascertained at a glance, and any barren stools may be placed in heat. Then the soil, consisting of equal parts leaf mould and loam, with a free admixture of sand, thoroughly incorporated, passing the whole through a half-inch sieve, may be prepared and the labels written. These early preparations allow of much work being executed in a short time. The labels should be alphabetically arranged on a garden tray or trays, one to each variety; as, for instance, "Avalanche" would be placed in the A section, whilst "W. H. Lincoln" would be situated at the bottom of the tray in the W. section.

Provide another tray or sieve on which are arranged a dozen or more empty 3-inch pots with a little paper over the hole. As the cuttings are taken the empty pots form good receptacles, and are deep enough to prevent the labels toppling over. There is then no risk of varieties being mixed in transit to the potting shed for insertion. Here duplicate dated labels are provided according to the number required, the latter

having been previously determined, and a temporary list drawn up for guidance. Labels of varieties yielding no cuttings or insufficient may be placed on a spare shelf, or in an empty box in the potting shed, being displaced as the requisite number is obtained. This will insure the inclusion of all varieties. When making the cuttings after the number is selected of each variety, all duplicates and parings should be swept off the bench. These simple precautions prevent that dire disappointment at blooming time through the cuttings having been mixed.

For preference long narrow pots (long toms) are used, inserting singly, thereby avoiding damage to the tender rootlets when repotting. Make the soil fairly firm, sprinkle a little silver sand on the top to work in, and insert the cuttings with a blunt dibber, making them firm at the base. Settle the soil with a gentle watering, using a fine rose. Transfer the cuttings to a frame, the bottom filled with ashes to keep them cool, situate near the glass in a house with a temperature of 40° to 50°. Damping must be guarded against, speedily removing all condensed moisture adhering to the glass. The names, dates, and numbers respectively should be entered in a book. At potting off time select the requisite number per each variety, discard weaker duplicates, check off in the book, and number the plants.—H. T.

VINE CULTURE.

IN the "Young Gardeners' Domain" I notice fruit is a subject conspicuous by its absence, so with permission I will give briefly the mode of cultivation which I have found gave the best results in a garden from which various kinds of fruit are exhibited largely. Now that many persons are starting their first houses of permanent Vines, I will deal with them first.

In our vineries the borders are entirely outside, so we cover those of our earliest houses with leaves to a depth of 18 inches, placing a light covering of litter over them in December. All is taken off in May, and a covering of leaf mould given, which helps to retain moisture during the summer. In late autumn the Vine borders have a dressing of gypsum or lime lightly forked in. The roots are close to the surface in all our borders with one exception, this supporting a cane each of Muscat of Alexandria, Ryton variety, and Mrs. Pince; yet all give fine bunches, many up to 7 lbs. weight when ripe, but Mrs. Pince colours poorly. Afterwards the borders are dressed with dissolved bones and sulphate of potash raked in. The borders are well made with the top spit of a deer park, and a sprinkling of bone meal, and half-inch bones mixed in.

Our two earliest houses, which afford ripe Grapes in June and July, were formerly Pine pits, and in the centre of each is a pit 8 feet wide and 7 feet deep running the length of the house; this is filled every year with Oak leaves, the earliest house about January 1st, the other some time later in the month. The leaves are turned half their depth as soon as heated; the heating destroys many slugs, and drives others to the surface, the top leaves then going under when turning. The leaves besides producing humid warmth, good for Vines when starting, are very useful for starting pot Strawberries, raising seeds, and striking cuttings during spring.

Before starting, the houses and Vines are well washed. I do not believe in painting Vines with a pigment, to be washed off in a short time with the syringe. The Vines are gently syringed twice a day till they start; afterwards it depends on the weather. On bright days they are syringed in the morning, and again before closing in the afternoon, and on dark days they may not require syringing at all. The floors are damped several times a day as required. We generally damp down with liquid manure the last time, as the ammonia from it helps to keep the Vines free from red spider and thrips.

Our Vines will not start freely in a temperature under 50°, 10° more in the day, and 5° less at night. After the Vines start we close the house in time to let the thermometer rise to 70°, increasing to 80° when the Vines are in flower, with about 65° in the morning. Syringing ceases when the Vines are coming into flower, and till after the Grapes are cut.—W. T., *Ireland*.

(To be continued.)

WINTER FLOWERING CARNATIONS.

Now is the time to commence propagating these useful plants. The cuttings should be taken from the old stems of healthy plants after the flowers have been removed. They should be pulled off, by which means a portion of the old wood will remain intact, and greatly facilitate the striking of the cuttings. After neatly trimming them they may be placed three in a 2-inch pot, or several in a 5-inch, using a compost of about equal parts of loam, leaf soil, and sand, passed through a quarter-inch sieve.

Care is required in inserting Carnation cuttings. The method I have seen adopted is the following:—Thoroughly clean pots are filled to half an inch of the rim with the compost, a thick coating of sand is placed on the top, and the cuttings dibbled in with a rather blunt dibber. By this means the sand trickles under and around the cutting, thus insuring it to some extent against damp. Give a good watering to settle the soil, after which little or no more will be required until they have rooted. Remove to the propagating house, and plunge the pots to their rims in cocoa-nut fibre.

When rooted pot singly in 2-inch pots, using the same compost as before, but in a slightly rougher state. Grow the plants steadily, increasing the supply of air as they gain strength, so that they may be ready to remove to the frames by the end of March. Winter flowering Carnations require to be stopped about twice to encourage them to make bushy plants. No plants of any description should be both stopped and potted at the same time. About the end of March, and again at the end

of May, are the most suitable times for stopping Carnations, certainly not later than June.

As the pots fill with roots give another small shift into 4-inch pots, water carefully, and give all the air possible, removing the lights altogether on fine days. If all has gone well, by the end of June the plants will be ready for their final shift into 7 or 8-inch pots. This time pot very firmly, using a compost of turfy loam, rough fibry peat, and leaf soil or spent Mushroom bed refuse, in about equal parts, with the addition of a few handfuls of bonemeal and charcoal, also plenty of sand. Some growers prefer to flower their Carnations in 5-inch pots, in which case the potting into 4-inch pots may be dispensed with. The plants should have plenty of room, and be dewed over several times a day with the syringe during sultry weather, carefully shading with tiffany during the hottest part of the day. Have the lights close at hand so as to be easily put on should heavy rains occur. Neatly stake with green-painted stakes, and on the advent of frost remove the plants inside, a low span-roofed structure being, perhaps, the most suitable, but avoid fire heating until absolutely necessary.

Beyond tying and disbudding little more will be required except careful watering and airing of the houses; 50° to 55° by night, and 55° to 60° by day, with a rise of 5° with sun heat will be found a suitable temperature in which to flower the plants. The application of weak soot water once a week during the flowering season will materially assist the blooms both in size and colour. The following is a short list of some of the varieties grown at Luton Hoo:—Mrs. L. de Rothschild, Mdme. Thérèse Franco, Miss Jolliffe (improved), Winter Cheer, Vulcan, Lucifer, La Neige, Miss Mary Godfrey, Jean Cresp, Countess of Monaco. The two last named are French varieties, and are not generally known. —YOUNGSTER.

BURCHELLIA CAPENSIS.

THIS is a beautiful old-fashioned plant, and was very popular many years ago, but it is seldom seen in modern gardens. It is a native of South Africa, and can be grown in an ordinary greenhouse, but is much more satisfactory in an intermediate temperature, such as in a warm

FIG. 22.—BURCHELLIA CAPENSIS.

conservatory or the cool end of a stove, as it grows more freely and flowers more abundantly than in a cool house. The flowers (fig. 22) are produced in clusters, and are of brilliant scarlet colour. A compost of light turfy loam and peat suits the plant well, and whilst growing frequent syringing is beneficial. Under ordinary treatment Burchellia capensis blooms in spring, when its bright flowers and fresh green foliage have a most pleasing appearance.—D.

HARDY FRUIT GARDEN.

Apricots.—Among the various kinds of wall fruits Apricots are the first to bloom. The trees being very hardy are easily excited into blooming, especially when growing on warm, favourable aspects. They need pruning early, so that the handling of the trees may be completed before advance is made to the blooming period.

Apricot trees are subject to the sudden dying off of branches, hence it is necessary to frequently unfasten the trees from the wall, remove useless material, and entirely re-arrange. Fruit is produced both on spurs and annual wood. Many of the spurs on Apricot trees originate naturally. These should be preserved if situated in favourable positions and at reasonable distances asunder. Artificially formed spurs are produced by shortening shoots which cannot be laid in for fruiting, or which, if retained, would cause crowding. Obviously all superfluous shoots cannot be utilised for spur formation. Ill placed, weak, unripe examples are not suitable. Growths of this description cut out. Encourage and preserve clean mature growths of moderate strength.

Pruning.—The natural spurs need no attention whatever. Growths issuing from the artificial spurs may be shortened closely. Select the best of the mature annual shoots for retaining, shortening them back to points where the wood is ripe, and a wood bud present. Wood buds are distinguished from fruit buds by their long pointed character. They are usually situated between two bloom or fruit buds, the whole being known as triple buds. Some shoots have only single buds, which may be wood or bloom buds. As a rule such shoots are unripe or lack vigour. Considering this, it is desirable not to employ them too freely.

Use a sharp knife in pruning. The face of the cuts should be away from the buds. This will direct moisture away from them and prevent possibility of decay. When re-arranging the trees dispose the principal branches equally over the available space. Lay in the secondary branches between, and, lastly, the young growths, those being preferred which spring from the upper sides of branches.

Peaches and Nectarines.—The treatment of these fruits is similar to Apricots. There is, however, one important difference in the general management. Young wood is, as a rule, selected, and laid in more largely for producing the fruit. Moreover, Peaches and Nectarines do not form natural spurs nearly so readily as Apricots. Artificial spurs require time for their formation, but young, well-ripened annual wood bears the following year. Thus the pruning and training is rendered simple, and the loss of branches from any cause can speedily be made good.

Pruning.—None but thoroughly clean and healthy branches should be allowed to remain. Cut out partially diseased or gummed portions below the affected parts. Exhausted branches remove entirely. Shoots that have borne the previous crop ought to be cut out in autumn. If still remaining remove now close to the base of the reserved shoot. Weak and immature wood is better dispensed with entirely.

The selection of the young growths for fruiting is the same as for Apricots. Apportion the ripest and best situated for training in. Shoots requiring shortening ought to be pruned to where the triple buds are situated. Comparatively short, mature growths may be left full length, provided the terminal bud is a wood bud. Shoots having unripe extremities need this portion removing, and any too long for the position assigned them in training must be shortened accordingly.

Cleansing Treatment.—The importance of commencing growth with clean trees cannot be over-estimated. Stone fruit trees are subject to attacks from green and black fly. They attack the trees early in summer, infesting the tips of young shoots. Later in the season red spider frequently proves troublesome to the principal leaves, chiefly appearing on trees in hot aspects during dry weather. Much may be done at this season to prevent these pests infesting the trees if precautions are taken to dress the stems, branches, and shoots with some effective insecticide which will cleanse the bark. Sulphur is an excellent antidote to red spider. A simple mixture of it with soft soap and water affords a dressing inimical to the pest, also to any other which may be lurking in angles and crevices or clustered round the buds. The addition of a little soot and clay to thicken and colour the mixture, bringing it to the consistency of thin cream, proves useful when applying the dressing. It causes the solution to adhere. The mixture must be laid on with a brush, working it in one direction from the base of shoots upwards when dealing with the young growth. This obviates the risk of dislocating the buds.

When the trees are dry the re-arrangement and fastening of the branches can be proceeded with.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest Houses.*—The prevalence of cold north-easterly wind and a murky sky are not favourable conditions under which to accelerate development, or is anything gained by hurrying the trees in the early stages of growth; but often the crop is lost by

pushing them when the external circumstances are unfavourable. Seek, therefore, to maintain steady, progressive, sturdy growth by making the most of sun heat, with early and judicious ventilation. Early forced trees also must be cautiously disbudded, as too early and all-at-once removal of the surplus growths gives a check, which may cause the fruit to fall, and the reaction that follows has its outcome in strong shoots. The proper method is to commence by taking off a few foreright shoots first, then proceed in a similar manner with those on the upper side of the branches, and those on the weakest part or lower side of the wood last. Leave a shoot at the base of the present bearing shoot to supply its place next season, and another must be left on a level with or above the fruit to draw the sap to the fruit. The upper growth should have its point pinched off at the third leaf unless it is necessary for the extension of the tree, when it may be trained in full length. In the case of trees extending the shoots necessary for the formation of the trees must be trained 12 to 15 inches apart. Instead of disbudding last year's extensions the shoots not required for laying in to form the bearing wood of next year may be pinched at the second or third leaf to form spurs, stopping subsequent growths at the first leaf. The bearing shoots on extensions should be 12 to 15 inches distance apart, and the extensions or branches a similar space asunder; for it is necessary in producing fine Peaches and Nectarines that the growths be sturdy, the foliage fully exposed to light, and cleanliness thorough; therefore allow no more shoots to be produced than is required for filling the vacant space, or to furnish the bearing wood of next year.

Syringing and a close moist atmosphere have a tendency to induce soft growths, therefore avoid an excess of both, but when the fruits are set swelling an occasional syringing in the early part of fine afternoons will assist them to cast off the remains of the flowers. Sufficient moisture beyond that of syringing can be secured by damping the paths and borders on dull days, and the foliage is then free to elaborate the sap, though its power is as yet small. When the fruits swell and are the size of horse beans, remove if too thickly placed a few of the smallest and those on the under side of the branches, but do not thin too severely, as excessive thinning, like extreme disbudding, often gives a check inimical to the fruit left; therefore thin by degrees, removing a few at a time, commencing with the weakest part of the trees. If aphides appear vaporise with nicotine essence or fumigate with tobacco, doing either carefully and moderately on two or three consecutive evenings, having the foliage dry and delivering the smoke cool. The foliage of Peaches and Nectarines is very susceptible of injury from tobacco smoke, an overdose being fatal to leaves and crop. If mildew appear, dust the affected parts with flowers of sulphur, or the advertised fungicides in powder may be employed, but apply very lightly. Be careful in giving air in cold weather, as draughts may cause the fruit to fall, and in clear frosty weather it is safer to allow the temperature to rise a little higher than to open the ventilators too much. Let the water supplied to inside borders be equal in temperature to that of the mean of the house; and to assist weakly trees to swell their fruit in the first stage afford liquid manure.

Trees Started at the New Year.—The buds having swelled and shown colour syringing must cease over the trees; but sprinkle the borders occasionally—morning and afternoon—on fine days, so as to maintain a genial condition of the atmosphere. If there is a superabundance of blossom remove that on the under side of the trellis, drawing the hand contrary way of the growth along the shoots. The temperature may be advanced to 45° to 50°, and 50° to 55° in the daytime by artificial means, and 60° to 65° from sun heat, ventilating freely above 55°, and leave a little constantly at the top of the house. Supply water to the inside border as required.

Trees to Ripen Fruit Early in July.—The house must be closed now, and the trees started at the commencement of February. Syringe the trees two or three times a day in bright weather, once a day sufficing when dull, and in severe weather merely damp the path and border. Turn the heat on in the morning so as to raise the temperature to 50°, keeping it at that figure until the decline of the sun; then allow the heat to fall to its night minimum, employing fire heat only to prevent its falling below 40°. Water the inside border if necessary, being guided by its condition, as there is a great difference in border requirements, those formed of retentive material not needing water nearly as often as those composed of loose porous soil.

Later Houses.—When the trees are kept under fixed roofs the buds commence swelling at an early period of the year, but where the roof lights are removed they do not come on sooner than those against walls in swelling. Ventilate freely in bright weather so as to retard the buds as much as possible, not omitting to water inside borders if they show the least indication of dryness, as this is one of the causes of the buds dropping. Houses and wall cases from which the lights have been removed should not have them replaced until the time for starting the trees or the buds are so advanced as not to be safely longer exposed.

Vines.—*Earliest Forced in Pots.*—When Vines are in full leaf they evaporate water rapidly, and require copious supplies of liquid manure or top-dressings of fertilisers washed in, always applying the liquid or water tepid, and taking care to not apply the manure water or fertilisers too strong. Thin the berries as soon as fairly set and somewhat freely in order to induce fine fruit, but not going to the extent of making the bunches loose, though that is better than wedged ones, yet the compact even-berried cluster is more pleasing and desirable. Damping is only necessary in the early part of the day in dull weather, and then in the afternoon on bright days. Maintain the night temperature at 60°, falling 5° on cold nights, 65° to 70° on dull days, 70° to 75° when mild and a

little sun, ventilating at 70°, increasing it with sun heat to 80° or 85°, at which keep through the day, closing so as to run up to 85° or 90°, and then sprinkling the paths and borders.

Earliest Forced Planted-out Vines.—Tying and stopping the shoots to one or two joints above the show of fruit where space is limited must have attention, removing the laterals below the bunch, except those from the two basal leaves, which, with those above the fruit, should be stopped at the first leaf, and subsequently as made. The stopping should be done when the leaf at the stopping joint is about the size of halfpenny, and very important for allowing more growth to be made than there is room, and not considering that a little lateral extension is desirable, causes overcrowding, and that is fatal to good results. Very close stopping, however, is not desirable where there is room for extension, the increased root action and elaborating power being corresponding to the foliage; therefore make provision for an enlargement of growth, and retain all the foliage consistent with its full exposure to air and light. Maintain a temperature of 65° at night, 5° more for Muscats when the Grapes are in flower. As some varieties do not set freely brush the bunches over with a camel's-hair brush or bunch of feathers, when the "caps" come off freely, and apply pollen taken from varieties that afford it abundantly, which usually results in a good set, especially if accompanied by a constant circulation of rather dry warm air. Commence thinning when the berries are about the size of small peas, it then being seen which berries are fertilised by their taking the lead in swelling. Ventilate carefully a little at a time, so as not to reduce the temperature, only to prevent its rising too suddenly and too high. Maintain a genial condition of the atmosphere after the Grapes are set by damping the paths and borders in the morning and at closing time. Water inside borders with tepid liquid manure not less in temperature than the house, or employ some approved fertiliser and wash in moderately.

THE FLOWER GARDEN.

Dahlias.—Strong young plants with one clear stem are preferred to old stools and several shoots, and that whether extra fine exhibition blooms or quantities of flowers for cutting or otherwise are required. Instead, therefore, of planting, or may be dividing the old stools, the better plan is to start these in gentle heat, and root cuttings from them. Set the roots closely together in a newly started vinery or other moderately warm house, covering all but the collars with moist soil. Numerous strong shoots will soon be formed, and these should be taken off with a heel when not more than 3 inches long. If left till they are too long to be taken with a heel—that is to say, till they are become hollow stemmed, they will not root. Fill 3-inch or rather smaller pots with loamy soil, put a little sharp sand in the holes made for a cutting, and fix the latter firmly. Close frames and a moist bottom heat are not desirable, the cuttings rooting most readily when set not far from hot-water pipes, or on an old fashioned flue in a moderately warm house. Cuttings thus raised and given one shift would make fine plants by the middle of May, but later rooted plants do not require a shift. Dahlias can also be easily raised from seed, though a stock of named plants well selected is much to be preferred to seedlings, many of which are seldom worth garden room. Sow the seed in pans, place these in a fairly brisk heat, cover with squares of glass. Shade and keep the soil uniformly moist. When the seedlings are of good size, and before they spoil each other, either place singly in 3-inch pots or prick them out 4 inches apart each way in boxes of good soil. The plants in either case would transplant readily, and flower freely this summer.

Cannas.—These are among the noblest of bedding plants, and suitable alike for massing or for associating with other plants. Not only is their foliage of a highly ornamental character, but the flowers are also very effective. The dwarf hybrids are particularly good, the flowers of these almost rivalling Gladioli in size, the colours also being very bright and good. In order to be sure of the seeds germinating quickly and well they must be soaked in water till they are swollen to double their original size. This may take place in a day or two, or it may be three weeks before they are sufficiently swollen and soft to place in soil. Bottles of water are most to be preferred, the seed being less likely to be left dry in these, and they may be either plunged in a brisk bottom heat or stood in the evaporating troughs or hot-water pipes. Sow the swollen seeds singly in 3-inch pots filled with moist warm soil, and plunge in a moderate strong bottom heat. When these pots are filled with roots shift into 6-inch pots, using a rich loamy compost, and with the aid of a little heat strong plants will be ready for bedding out early in June.

Clumps that have been kept through the winter may be started in heat as advised in the case of Dahlias, and when the growths are 2 inches or rather more in length, split up and divide so as to reserve a few strong roots with each shoot. Potted off singly they will soon become re-established, and a good stock of plants will be the result.

Pentstemons.—In order to be certain of perpetuating good named varieties cuttings ought to have been rooted last autumn, wintered in cold frames, and prepared for bedding out in April or May. Seedlings, however, are quite as beautiful as named varieties, a single packet of seed giving a large number of plants. Sow the seed at once on the surface of well prepared pans of soil. It is a good plan to moisten the latter prior to sowing the seed, covering lightly with fine soil. Place in a frame over a hotbed or in a fairly brisk heat, cover with squares of glass, and shade heavily till the seedlings appear. The latter being early, pricked out in pans or boxes of good fine soil, and kept for a time in gentle heat, will soon be large enough for hardening off, and if planted out in beds or borders of well prepared soil by the middle of May a fine display will be made this season.

Antirrhinums.—These should be raised from seed as advised in the case of Pentstemons, and, in common with the latter, will not prove very showy if the seed-sowing is much longer deferred or the seedlings are neglected. Antirrhinums can be had in separate colours, and by good treatment will make a grand display, a dry season not militating severely against them. The best whites are particularly effective, and serviceable for cutting from.

Sweet Peas.—Where many cut flowers are required early Sweet Peas ought always to be raised under glass and planted out. The newer varieties are particularly good for cutting, and seeing that the seed is dear and distributed in small quantities these, in any case, ought not to be trusted in the open ground. Fill the requisite number of 3-inch pots with good loamy soil, and in each sow seven or eight seeds. These germinate surely and quickly in gentle heat, but the plants ought soon to be hardened and planted with their balls of soil and roots intact where they are to flower. Rows or patches of seed of the common varieties may also be sown in the open at much the same time as the earliest garden Peas. Grow plenty of the old white, and abundance of a good scarlet variety is always appreciated.

Mignonette.—Much that has been advanced concerning Sweet Peas is also applicable to Mignonette. Enemies of various kinds render it next to useless to sow seed early in the open, but a few dozen plants, raised in small pots and planted in good soil before they become badly root-bound, will give off early spikes of flower, and perhaps keep flowering strongly all the season. Garraway's White ought to be grown everywhere.

THE BEE-KEEPER

HIVES WITH TEN STANDARD FRAMES.

It is always pleasing to have a critic "turn on the search light in a friendly spirit," as reflected by "G. H." (page 63). This feeling I reciprocate. More light on this subject will be welcomed by all bee-keepers, as it is only by discussing the various ideas that continually spring up among the apiarians who are readers of the *Journal of Horticulture* that we are able to keep in touch one with the other. I will at once state that I do not wish to infer that the system of bee management advocated in these pages is the only one that can be profitably adopted; but having followed the system for many years with a fair amount of success I have no hesitation in recommending others to try it.

"G. H." is somewhat difficult to follow, as in his previous remarks (page 619) he says, "If we want to take as much surplus as 250 lbs., and leave 100 for stores, we must go in for larger hives;" now he says, "30 lbs. is sufficient for winter stores." One is tempted to ask the question, Is the former theory or practice? as from his own showing 70 lbs. of stores would be useless in the hive. I thoroughly agree with this contention; but why create a large hive for holding stores that are useless? If that amount were stored in supers it might be utilised in many ways. This is the great advantage of the doubling system, all the honey that it is possible to obtain being secured in saleable form.

USING OLD COMBS.

Some bee-keepers, including "G. H.," have an objection to using combs that may at some time or other have been used in the brood nest, and contend that the honey is not so good as that obtained from newly built combs which never contained brood. That this is a fallacy I have not the least doubt. The seasons are too short, and the time of the bees too valuable to waste over building new combs when some good old tough ones are at hand that will not break down when passed through the extractor. New combs require very gentle treatment, or they will do so.

It does not matter in the least whether the combs are white or brown for extracting purposes, the sample of run honey will be as good from one as the other. A good stock of old combs is the sheet anchor of profitable bee-keeping. And to show that I do not advise others to do what I do not practise myself, I may say that I have several hundreds in stock which have all contained brood at one time or other. These will all be used for extracting purposes in due course. The sample of honey will be as good in colour and flavour as from newly made combs. The plan I follow is a great saving of labour to the bees, which anyone may prove for himself, by giving them guide combs or full sheets of foundation, and note the result.

If full sheets of foundation are required annually it would prove a serious item of expenditure in a large apiary. In contrast to this place an empty brood comb over a strong colony in the height of the season, and see how soon they will have it cleaned and ready for storing honey. But if we want "honeycomb of spotless whiteness" then new combs must always be used; if they are at all discoloured the cappings will not be white, and will then be only

third-rate in quality. It will not be the honey that will be affected, only the comb. The honey will be found to be equal in quality to that obtained from white combs.

SYSTEM IN BEE-KEEPING.

In bee-keeping it is an advantage to work on certain lines, and have a system in managing all the details pertaining to the industry. I recommend the standard frame because it is now well known, and is generally recognised throughout the country. This simplifies matters when speaking or writing of a frame hive.

It is of little consequence whether the frames are 2 or 3 inches deeper or longer, quite as good results will probably follow by either; but if good results can be obtained from a recognised size such as the standard frame (and I contend that there can) it is much better to keep to the one size than for no two bee-keepers to have their frames alike.

The system advocated of confining the queen to ten frames and supering with frames of the same size or shallow frames, now much used by some bee-keepers, or by crates of sections, one and all have the same effect on the colony. The bees will not store their surplus honey in the brood nest if ample space is provided in supers. I have often had sixty-three sections on a strong colony of ten frames at one time. These require to be well finished before removal. With standard frames for extracting it is different. If three parts of the cells are sealed over it will be ripe enough for extracting.

It would be an advantage if correspondents would state the size of their frames and hives when speaking of large hives, as the hive mentioned by "G. H." as containing "twelve frames 20 inches by 8½ inches" is not so large as the hive he condemns when doubled. The latter system, too, provides a ready means of raising young queens, without which no apiary can be successful.

"G. H." cannot be serious when he assumes that it was owing to the hive having standard frames in the same apiary as the above that no surplus was stored. The cause may be summed up in one word—"Management."—AN ENGLISH BEE-KEEPER.

[Referring to the above, it may be interesting to readers of the *Journal of Horticulture* if "G. H." would state the dimensions of his large hives, and his system of working them for run honey, as the hive recommended by "An English Bee-keeper" when doubled for extracting purposes holds twenty frames if required, which is large when compared with many hives.]

HONEY AND HIVES.

I AM sending off to you a sample of honey. The section has been one in the number that have taken three prizes, the first at Howden, also the first at Goole, and the second at the Great Yorkshire. The candied honey has taken two prizes in strong competition. I have found large hives far the best. I have the friendliest feeling for "An English Bee-keeper," and should like to pay him a visit, and to have a return visit from him to compare notes.—S. REMMER, *Knedlington Manor*.

[The sample of honey in the comb is excellent in colour and consistency, while the flavour is good. Unfortunately the section was smashed, but enough remained to show that it was well finished, the cappings being thin, honey of good colour, and in admirable condition for present use, thus showing that the honey was well ripened before its removal from the hive, and had since been kept in a suitable temperature which had prevented granulation. This is a fact that should always be kept in mind, when honey becomes candied in the comb (usually caused by being stored in too low a temperature) it is useless for table.

The granulated sample is also of excellent quality (evidently collected from white Clover), being of good colour and fine in the grain. The aroma is not so pronounced as in some samples we have tasted, but the sample is highly creditable for the season. The "get up" of both samples is good, the section being double glassed with lace paper edging, which gives it a very neat appearance, and also protects the comb from damage.

The run honey was put in a screw-top white glass jar, and neatly labelled "Pure Honey." We think it would be an advantage if all bee-keepers would label their produce "Pure English Honey," with their name and address; this would be a guarantee of its purity.]

AMERICAN FRUIT IN VIENNA.—Apples and Pears from the United States and Canada have been selling on the Vienna market, the first at from 5d. to 8d., and the latter from 3d. to 1s. per kilog. The quality is good, the exporters fully understanding that only good wares would sell at a profit. The fruit growers of Great Britain are therefore, says a contemporary, not alone in experiencing the competition of the American in the home markets. This may, this season, have been enhanced by the enormous fruit crop of excellent quality harvested in America, accentuated by the smallness of the crops on the Continent.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. A. F. Barron, The Royal Gardeners' Orphan Fund, Chiswick, W.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Lycaste Skinneri (*J. C.*).—The Orchid flower sent is that of *Lycaste Skinneri*, a fairly good form and flowering at its correct season. The book you mention contains an excellent list of Orchids, with lucid descriptions and very well done figures of a great many species, but owing to the great scope of the work the cultural notes are necessarily short. No separate book that you may purchase can contain full cultural details such as are given in the horticultural press, while any special subject where you may be at a loss we shall have pleasure in assisting you.

Apple Tree Twigs and Branches Diseased (*F. W. C.*).—The "pieces of Apple stems" are a "sight," the twigs being smothered with mussel scale (*Mytilapsis pomorum*), beneath the "shells" of which are numerous eggs of the insect, which is now for the most part dead; but the eggs will develop fresh "scales" in the course of a few weeks, and these render the disease worse. We were pleased to find an egg of the true or winged male—a rare occurrence—and it is already developing nuclei, with antennae discernible. The branch has "something in it," and more than it can hold, for the "fruits" of the canker fungus (*Nectria ditissima*) are breaking through the bark in the finest crop we have ever seen. Nothing could be better for settling the vexed question as to its being the cause of the disease, for here (in your specimens) we have it on clean living bark, and the scar follows as a consequence. The "fruits" are distinctly visible to the unaided eye, and appear peeping through the bark as reddish brown pimples. We are extremely obliged to you for the specimen, and will see if we cannot procure a sketch of it and some account of the parasite for publication in our columns. In the meanwhile wash the tree or trees with a caustic solution—namely, 1 oz. caustic soda, 98 per cent. purity, and 1 oz. commercial potash (pearlash), water 1 gallon. Dissolve the caustic soda in a pint of hot water by itself, also the pearlash by itself in a similar amount of water, then add the last to the former, and the remainder of the water hot. When at a temperature of 130°, not more, and not under 120°, apply with a clean half-worn paint brush, taking care to reach every part of the tree, wetting every particle of the stems, branches, and twigs, but not more, as running of the solution down to the roots may injure them. Choose a fine day for the operation, when the trees are dry and not frozen, and do it as soon as possible, at any rate before the buds begin to swell; but if done now you will get at the "fruits" of the canker fungus, and the solution will sink into the cracks and destroy any mycelium it reaches. The solution will clear the tree of its overgrowths of lichen and moss, kill the scale and their eggs, leaving the bark clear and smooth. It will not, however, restore the dead parts of the tree killed by the canker fungus to life; those you must cut away and burn, dressing the wounds on any living branches with the following composition:—Dissolve 1½ lb. softsoap by boiling in a gallon of boiling water, remove from the fire, and add while boiling hot (not on the fire) half a pint petroleum, and stir briskly till thoroughly amalgamated. Procure some clay, dry it, then pound it to powder, and add enough of this to the emulsion to form a creamy composition, which apply with a brush to the wounds, coating them so as to make level with the bark. This will do something for the canker fungus mycelium, and better encourage growth of new bark over the wound.

Orchids (*A. McL.*).—Your card is sent to the author referred to, who will probably write to you on the subject if he can do so usefully. We are unable to give the desired information.

Mushrooms and Carrots (*Colonel*).—The more Carrots consumed by horses the less suitable is the manure from the stables for the production of Mushrooms. It has been found that when Carrots were largely used Mushrooms could not be grown in anything approaching a satisfactory manner. The subject, and most others, is treated in "Mushrooms for the Million," post free 1s. 2d., from this office. All persons who experience difficulty in growing Mushrooms should read the work attentively.

Blue Cornflower (*W. W.*).—London's "Encyclopaedia of Plants" says, "It is found everywhere throughout Europe on gravelly soils;" and in "The Wild Flowers of Great Britain" it is stated to be "A common weed in corn fields, where it is met with all over the country." We know of its having been found in Scotland, where it is known as "Blue-bonnet;" in Wales, where it is called "Crammenog yr yd;" and in Ireland, where it is termed "Gormon." The remark had reference to the Midlands, and was founded on observation. We are much obliged for your note stating that you "have seen the fields actually blue with it near Blair Athol in Scotland."

Ammoniacal Liquor and Wireworm (*P. H.*).—Gas liquor will kill wireworms, but the difficulty is to reach them with it at this time of the year, as they are so deep in the soil, while if not used until sowing time there is danger of injuring the plants. It is best used, about 5 gallons per rod, a fortnight before sowing the seed, and to prevent loss of ammonia point it into the soil with a fork. If used after the plants appear dilute with five times the quantity of water, and in using pour it between the rows, not over the plants, a gallon per square yard being a good watering. If it be Carrot grub you mean by wireworm, supply now or as soon as the ground is thawed and in good working order 3½ lbs. kainit per square yard. This is useful against Onion grub, but there must be means taken to prevent the flies depositing their eggs, as they often come a considerable distance, and in the plants the grubs are not easily reached.

Chrysanthemum Buds (*S. S.*).—What you ask for have appeared in the form of illustration, and you will find them in Mr. Molyneux's popular work on the Chrysanthemum. A "crown" bud is a bud that forms at the apex of a shoot, and very soon two or three growths issue below it and grow far beyond it if permitted to do so, the bud then perishing. It, therefore, in a natural way does terminate growth. If the bud forms in May it is the "first crown;" if growths extend and another bud forms in July it is a "second crown;" or if it form in August, which is a better time, as then, if the surrounding growths be promptly removed, the bud receives the support which they would otherwise appropriate, and under good culture develops into an exhibition bloom in November. All buds which form in the crowns of the plants, no matter when, and other growths break from just under them, and would, if permitted, extend beyond them, are crown buds. Later the growths are of a different character. A bud forms as usual, but instead of growths breaking from its base, other buds cluster round it. These may or may not be removed, but whether they remain or not the growth of the plant terminates in the largest central bud, and this is consequently the "terminal." The blooms are, as a rule, smaller than "crown" buds, but often neat and attractive. We hope the matter is now clear to you, though it may possibly be referred to again.

Zonal Pelargoniums Diseased (*Constant Reader*).—The plant has gone off by a disease closely resembling that known as "sleepy disease," "drooping disease," and "black stripe" in Tomatoes. The fungus, which is the cause of the disease, attacks the plants at the roots and ascends the stems, the hyphae growing between the bark and wood, passing into the petiole of the leaves and causing them to die from below upwards. These parts, however, and the tender parts of the shoots die the soonest, so that the plant appears to go off from above downwards. The disease is a very old one, frequently sweeping off whole pots and pan-fuls of cuttings, and very disastrous to plants when a year old, even plants in beds not escaping. Some varieties are more prone to it than others. It is generally found when the plants are grown in soil containing a large amount of vegetable matter, and kept too moist. The fungus may be seen as small black patches where it has broken through the cuticle in somewhat large and aggregated pustules, which are whitish in colour, and the minute blackish olive heads are the easier seen on that account. It is *Sporocybe byssoides*, *Bon.*, and has a nasty habit of causing young growths of Ivy to turn black and die, sometimes doing the same with Box, and too often for Clematis. We have found quicklime to act well when it has been mixed with the loam some time in advance of using, as this reduces the organic matter, and the plants are supplied with nitrate of lime instead of having the fungal germs placed directly in contact with their roots. The lime should be air-slaked chalk-lime, dry and floury, employing about 5 per cent., or one-part lime to twenty parts of turfy loam. There were some mites on the roots, full-grown, eight-legged specimens, between the bark and wood on the root-stem, and appeared quite at home. Perhaps they had got there through the fungus having ruptured the bark. Then there was a creature about one-third of an inch long, with a black head and grand pair of jaws, but whether it was making a meal of the mites we could not make out. It, however, was an apparently carnivorous species, therefore not hurtful to the plants. We can only advise the destruction of the affected plants, and particular care in respect to soil and watering.

Pruning Potted Maiden Apricot, Peach, and Nectarine Trees (B. D. R.).—The proper method is to cut the trees down to the point marked in your sketch A, shorten the two pairs of side growths to about half their length, or, say, the lower to 6 inches and the upper ones to 3 or 4 inches. Next year take a shoot from the top and train it upright, pinching it at 12 inches, and if it break again allow growths to 6 inches, then pinch. Stop the side branch growths at 6 inches; second growths to 3 inches, and in that way you may get as fine pyramids as need be, it being simply a matter of shortening the leader and getting side branches as you go along each year. By proceeding on the lines marked out by B in your sketch you will get a fairly good pyramid, but the vigour will in a few years increase in the upper part at the expense of the lower and weaker, the tree branches developing into a standard, as you say. There is no difficulty in pruning standard Peach trees; it is a question of thinning in summer to prevent overcrowding of the foliage, removing very strong and very weak shoots, retaining the sturdy and short-jointed for bearing.

Garden Soil Infested with White Insects (A Very Old Subscriber).—Had you sent a little of the soil containing the insects we might have been able to tell you what they are and to advise more definitely. As you have tried "quicklime (a heavy dressing) salt, and soot," all excellent dressings for destroying ground pests, you may use gaslime fresh from gas works at the rate of 4 tons per acre, or 56 lbs. per rod, or a little less than 2 lbs. per square yard, but upon the distinct understanding that it be spread evenly and left on the surface for six weeks before it is dug in. Make no mistake in this matter, and it will not make any about the pests in the soil. It ought to be applied in the autumn, or at once, so that it can lie on the surface as stated. As you may not be able to wait six weeks you may use half the amount of gaslime, 2 tons per acre, 28 lbs. per rod, leaving it on the surface three weeks and then work into the soil by digging with a fork, taking small spits. This will usually banish, if not kill, most ground pests, and without prejudice to the crop following. If you cannot use the gaslime apply 3½ lbs. of kainit per rod, distributing evenly before the middle of February, or as soon afterwards as the ground is thawed. This will not injure anything in the way of trees or plants, and it will make an end of most grubs. In putting in crops employ 3½ lbs. of dissolved bones, dry and crumbling, per rod, and when the plants are growing apply 1½ lb. nitrate of soda, finely crushed, per rod. This management ought to give you abundant crops where you can simply grow nothing on account of the insects.

Gros Colman Grapes Cracked at the Footstalks of the Berries (W. W.).—The berries are in a sad condition from the cracking around the footstalks, and covered there with a mould—a fungus, *Aspergillus glaucus*, *Link*—the conidial condition of the higher form known as *Eurotium herbariorum*, *Link*. The fungus is found on fruit, branches, leaves, and all kinds of decaying organic matter, and wholly regarded as a saprophyte; but that does not mean that it will not attack fruit other than in a state of decay, for when a fruit has ripened it is practically dead, and the least flaw in the skin of a Grape or other fruit is sufficient to give the needful access to the fungal germ-tube, and then decay proceeds rapidly. Whilst the skin of the berries is intact the fungus has no power to break it down, but the presence of moisture for any length of time thereon so weakens the cuticular cells that the germinal tubes easily pass through the skin. The cause of the cracking was no doubt the great quantity of rain in the autumn and until recently continued, the soil being heavy and surcharged with water, and the berries thus gorged with fluid simply burst their skins. This in a dry atmosphere is at the nose, and in a moist one around the footstalks, at least such is our observation. Keeping the houses damp in the summer time to prevent red spider would not cause the Grapes to crack after they were ripe. It is the wetness of the border and also that of the house recently which has caused the cracking or decay of the berries at the footstalks, for there is the mould on several of the berries without any cracking of the skin. More air—some constantly—would no doubt have made a difference, as it was the accumulated moisture on the berries that provided favourable conditions for the growth of the fungus.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (J. P. A.)—No person living could name the Apple in its crushed and semi-decayed state. In size and shape it resembles Old Nonpareil. (T. W.).—1, Cornish Aromatic; 2, Royal Russet; 3, The Queen. (L. C.).—Tyler's Kernel. (A. M.).—1, Court Pendu Plat; 2, Golden Noble; 3, Cox's Orange Pippin.

PREPARING FOR THE LAMBING SEASON.

No excuse is offered, and we think none is required, for again presenting to our readers a few hints and a few warnings to that they may lay to heart before this critical time for the flock master arrives.

As so far we have only been able to wrest from Nature one corn harvest, we have still but one crop of lambs per year, and that being a crop of great value it behoves us to use all diligence and skill to preserve these young lives, and to prevent as far as in us lies undue mortality among the ewes. We have just read with great pleasure and profit an article in the last issue of R.A.S.

Journal on the "Lambing Pen" by Mr. Harold Leeney. He has gathered many practical details from practical men, and putting the whole into an interesting form, has done good service to agriculture.

He begins by giving some excellent hints as to the condition of the ewes and ram in the autumn, and urges extra care and extra feeding for the last six weeks before lambing. There are always some weakly ewes which want the best of food to carry them through their time of trial, and all need some milk-producing diet.

The construction of the lambing pen is of the first moment. Shelter there must be, but not too much of it. The sheep by nature is a hardy animal, yet it is quite possible that even a sheep may have too much of the north-easter. Hurdles and straw make capital pens; there must be a bit of roof, well thatched, to turn continuous wet—we have seen where straw was plentiful a wall of it built all round the fold. Other material may be employed, but there is nothing like straw yet. The fold should be large enough to prevent overcrowding, and some shelter must be provided for the man or men on night duty. Some farmers provide the shepherds with extra refreshments for the nights, and we think the master is the gainer by so doing.

Supposing the lambing is carried on in a permanent building (which at the best is but a bad plan) the greatest care must be taken to keep the floor sweet and wholesome. Dry earth mixed with lime and ashes is antiseptic up to a certain point, but where temporary shelters can be got, and the fold changed every year, there is a much greater prospect of a healthy lambing season. Always keep a few pens ready for the reception of invalids that require a little extra attention.

No offensive matter must be allowed to remain for one moment in the lambing pens, and it is well to forbid the shepherd to have anything to do with dead bodies—there is no knowing how easily disease is conveyed by a man from a dead to a healthy sheep. The pens must be kept absolutely quiet—no dogs, no strangers, and it is well to bring the forward ewes up at nights, some days before the lambs are due.

A shepherd never knows what a day or a night may bring forth, and it is the wisest plan to have all medicines and disinfectants and appliances at hand. First about himself—he must pay the greatest and most minute attention to the disinfecting of his own hands—constant washing with carbolic soap in a metal bowl, and he should take care that his nails are well cut back, as they harbour dirt and infection, and may unwittingly give many a scratch. Carbolic oil, disinfecting fluid, a bushel or two of lime, a few penny sponges, and pieces of soft rag are all things he must have, with a little tin to heat milk for weakly lambs. A sauce bottle with a long neck makes a capital vehicle from which to give drinks. A bottle of cordial for weakly animals, a bottle of scour mixture, another of laudanum, and another of castor oil. There are other things that may be added, but these are what are needed daily and hourly.

There are two distinct classes of shepherds. Those men who know when a ewe needs assistance in lambing, and those who are for ever meddling, and thus retarding the efforts of Nature. No books or diagrams will help a man much—it is only by practice and careful observation that a good shepherd is made. Before offering any assistance to a lambing ewe the man must anoint not only his hands but any instrument he is likely to use with carbolic ointment, and a dressing of carbolic oil used for each ewe after lambing is always a safeguard.

If after properly cleansing a ewe is observed to strain she should at once have a little gruel with a dose of laudanum every two hours till the trouble is subdued.

Sometimes there is considerable loss of lambs from overlaying. If a ewe is weak she is very liable to drop rather than lie on her lamb; she is really too ill and weak to know what she is doing. Also when the weather is very cold the lambs will lie so closely to the ewes that if the latter move slightly a lamb's head may be

entirely covered by thick wool, and so quickly smothered. We know farmers who always have triangular pens on purpose to avoid overlaying; the lambs get in the corners, and so escape. These pens are best made by fixing hurdles radiating from a central point. A few short hurdles made on purpose just the right length make capital gates to the pens, and eight hurdles plus eight gates will make eight pens.

If a lamb scour it is generally the fault of the dam, and she should have a dose of salts with a little gruel and ginger, the ewe being milked by hand, and her lamb suckled on another ewe for a day or two.

Lambs often get swollen joints. This is caused by variations of temperature (hot days and frosty nights). A dry lair and a dose of castor oil may benefit; but if really bad a cure is a slow as well as difficult matter.

WORK ON THE HOME FARM.

We are having a little frost at last, and though it is not very severe and does not look like lasting, we are thankful for it, such as it is. Much more is required to make a good spring mould of the sodden land. Those who have much manure in the yards are now getting it led out. We have nearly all ours out either in hill or ploughed in for Potatoes. We are now carting drain pipes for some underdraining on the eve of commencement. It is very heavy carting, as the land is exceedingly wet, and the necessity for the work very evident.

Should the frost continue threshing days will be more satisfactory. Stack sides have so seldom been dry of late that grain has lacked the good condition and dry handling that it should now have. Good Barleys are getting much scarcer, but maltsters seem able to buy plenty of foreign, so there is no better demand. Grinding Barleys are almost unsaleable, and are now being freely fed to stock. This has had an effect on the Maize trade, and should influence the values of cakes.

We see a few early lambs, but this district is too far north for general lambing yet. There will be no excuse for giving ewes too many Turnips this season, for there are very few for them. One neighbour will not have a Turnip left by March 1st, and he generally has his hoggs on roots until the latter end of April. We are not so badly off as this, but we have increased the cake to the sheep nearly double, and this has lessened the consumption of Swedes. Sheep must pay for an extra allowance of cake this year.

The same applies to cattle, for so few are being fed off, owing to root scarcity, that spring beef, and therefore very fresh stores nearly beef, are sure to meet a good market in April. The dairy cows must not be stinted as to diet now; butter is a better price than it has been since last winter. It is easier to let a cow run off in her milk than to get it back again. We have found it necessary to have each cow's milk carefully measured at intervals to keep a check on the feeding as well as milking of the herd. Some large milk producers have the milk measured weekly, but this seems to us oftener than is necessary.

Pork is as cheap as ever; the low price has now continued longer than is usual, but we notice that American imports are falling off, so the swing of the pendulum may be nearer than we expect. Small pigs at 10s. each might be a good investment, as pig food is sure to be cheap for another six months.

* Covered with snow.

REMARKS.

- 17th.—Fine, bright, and sunny all day; freezing in afternoon, and bright night.
 18th.—Fair early, and slight mist; a sunny afternoon and fine bright night.
 19th.—Overcast early; fair at 9 A.M. and up to noon; overcast at 1.45 P.M. and rest of day; slight rain in evening; overcast night.
 20th.—Dull damp air; spots of rain at 8.30 A.M.; generally dull; breezy at 4.30 P.M.
 21st.—Small snow early morning and flakes at 9 A.M.; dull all day and night.
 22nd.—Snow early; bright sun at intervals till noon; snow nearly all the afternoon, but not heavy—total, about 1 inch.
 23rd.—Fresh snow, about $\frac{1}{4}$ inch deep at 9 A.M., and snowing at intervals; sun bright at 11 A.M. and all morning; brilliant at 1 P.M.; total depth of snow, 2 inches; fine night.

A cold week, rather colder than any week since February, 1895, but, of course, not to be compared with the severity of the middle of that month.—G. J. SYMONS.

BARR'S ILLUSTRATED SEED GUIDE contains a Choice List of the best Seeds for the Flower Garden and Greenhouse.

ALL SEEDS CARRIAGE PAID ON RECEIPT OF REMITTANCE

We guarantee all our Seeds to be of the finest selected strains, and of highest growing quality.

BARR & SONS

12 & 13, King Street, Covent Garden, LONDON.

ANT. ROOZEN & SON'S

CHOICE

VEGETABLE & FLOWER Seeds

FOR PRESENT SOWING,

AND

BULBS AND PLANTS

FOR SPRING PLANTING.

COLLECTIONS OF VEGETABLE AND FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM, HOLLAND, or to our General Agents,

Messrs. MERTENS & CO.,
3, CROSS LANE LONDON, E.C.

No. 867.—VOL. XXXIV., THIRD SERIES,

Barter's TESTED SEEDS.

New and Improved Flowers.

CARTERS' HOLBORN PRIZE PRIMULA.

We commenced growing our own seeds of this popular winter-flowering plant forty years ago, and have since carefully selected and improved our strain, that we unhesitatingly pronounce it the finest in cultivation; and as we try all others each season for comparison, our statement is authoritative. We were the originators of the Blue Primula, which resulted in some cross-breeding experiments we were making to this end; our collection also comprises the following beautiful colours:—Scarlet, Carmine, Magenta, Ruby, Vermilion, and White.

Each separate, in Sealed Packets, price
2/6, 3/6, and 5/-, post free.
ALL COLOURS MIXED, in Sealed Packets, price
2/6, 3/6, and 5/-, post free.

CARTERS' BRILLIANT PRIZE CINERARIA

Our House has long been famed for this beautiful flower, and our strain is unequalled for profusion of bloom, size of flower, and general habit. We grow all our own seeds, and test other strains each season.

In Sealed Packets, 2/6, 3/6, and 5/- each, post free.

CARTERS' VICTORIA PRIZE CALCEOLARIA

Our fine strain is well known at all the leading Horticultural Exhibitions, where magnificent specimens have secured First Honours on nearly every occasion.

In Sealed Packets, 2/6, 3/6, and 5/- each, post free.

CARTERS' CROWN JEWELS BECONIA.

The strain we offer of this lovely flower is saved from one of the finest collections in Europe.

Single Flowers—1/6, 2/6, and 3/6 per Packet, post free.
Double Flowers—2/6, 3/6, and 5/- per Packet, post free.

CARTERS' INVINCIBLE PRIZE GLOXINIA.

Our strain has proved its superiority over all others wherever exhibited throughout the British Empire, and cannot be surpassed.

In Sealed Packets, 2/6 and 5/- each, post free.

CARTERS' PICOTEE POPPY.

A new and lovely race of striped Poppies, admirable for mingling with the much-admired Shirley varieties.

In Sealed Packets, 1/6 and 2/6 each, post free.

SHIRLEY POPPY (Rev. W. Wilks' Select Strain).

A strain of unusual beauty, rigidly selected by its original nominator, the worthy Secretary to the Royal Horticultural Society.

In Sealed Packets, 1/- and 1/6 each, post free.

CARTERS' CARMINE ABRONIA.

Quite a new colour in this pretty Verbena-like trailing plant.

In Sealed Packets, 1/- each, post free.

We hold hundreds of letters from customers confirming all we say about our Flower Seeds; some are reprinted in our publications for the benefit of those intending to purchase.

Illustrated CATALOGUE, Gratis and Post Free.

Journal of Horticulture.

THURSDAY, FEBRUARY 4, 1897.

CYCLAMENS.

IT was natural to expect that after the memorable battle of Hastings, which completed the Norman conquest of England, William the Conqueror's companions should have shared in the partition of the new conquered territory in the counties immediately adjoining the scene of that fatal field. There were rich lands which reminded them of the Normandy from which they had come, and in truth we find notices of some of them go as far back as the "Battel Abbey roll."

Now Godinton was one of these places. It was assigned to John Godinton, and after many vicissitudes passed by marriage into the family of the Tokes, who were descended from Le Sire de Touque, sometimes written Toke, Tooke, Tucke, or Toc, who also came over with William the Conqueror. The marriage by which it came into the Toke family was that of Joane, daughter of William Goldwell of Godinton with Thomas Toke of Westbere in the reign of Henry VII. on the failure of direct male heirs. Amongst the descendants of this Thomas was one Nicholas, commonly called Captain Toke, who was buried with his five wives in the chancel of the parish church of Great Chart. It is recorded of him that in his ninety-third year he walked to London, being then a widower, to pay his addresses to a lady whom he wished to make the sixth Mrs. Toke, when he was taken ill "and presently died." It continued in the family of the Tokes until 1895, when it passed by purchase into the possession of Mr. George Ashby-Dodd.

Godinton House is situated within one and a half mile of Ashford; the park contains some fine trees, and is noted for a "Chestnut Toll," which is a landmark in the surrounding country. The house is one of those delightful specimens of Tudor domestic architecture, which show how much more beauty was appreciated in those days than in the Victorian era, where show and glitter are more sought after than the quiet and restful beauty which marks these old houses. The hall and staircase are especially beautiful on account of the ancient carved wood, and have several stained glass windows containing the family arms of the Tokes; the drawing-room is also a curi-

ously wainscotted room, with much oak carving. The house is now being considerably enlarged under the superintendence of Mr. Blomfield, the well-known architect, so that nothing will be done, we are sure, to alter the character of the house or offend the eye.

In these days when so many of the gardens of our nobility and country gentlemen are more or less market gardens, where every bit of produce is sold in consequence of the difficulty which is occasioned by the depression in agriculture, it is pleasant to be able to record an instance where the reverse process is going on, for the gardens here have hitherto been of the ordinary commonplace ones which are everywhere to be found, but I am very much mistaken if they will not in a few years present a very different appearance. I found them on my visit in charge of the son of a very old friend, Mr. Frost, whom I have known for the last forty years at Turner's Nurseries, Slough. He used to have under his charge those magnificent specimens of Show and Fancy Pelargoniums which were such marvels of fine culture, and afforded such delight to all lovers of beautiful flowers. Alas! they seem to have had their day, and "Othello's occupation is gone," for Mr. Frost has now under his care Cyclamens and other popular flowers; but I suppose we must not complain. It was hardly possible to conceive how any further improvement could be made in the colouring, form, and texture of the flowers raised by Messrs. Hoyle, Foster, and Turner.

Mr. Frost's son seems to be an able and intelligent gardener, and has already begun to make things look differently. A Rose garden is being now formed, Chrysanthemums are well grown, and have already raised somewhat of a commotion at our local shows. Beds of Carnations look well, but the point which most struck me on my visit there lately was the splendid house full of the Persian Cyclamen. There is no flower in which I think a more marvellous change has taken place in the last twenty years than this. I well recollect the time, very many years ago, when it was considered one of the most difficult flowers to propagate, and old Donald Baton thought he had conferred a great boon upon gardeners when in the pages of the Journal he told them to cut up their roots in order to multiply their plants; moreover, we were directed to shake them out of their pots after flowering, and plant them in the open ground. Now all this is changed; they are raised in immense numbers from seeds every year, and with careful management they bloom in twelve months after the seed-sowing, and they not only have increased in size but exhibit great variety in their colouring. They are to be found from pure white to the deepest crimson, and various shades of pink, salmon and rose. But amidst all this improvement there is one thing we must regret; the flower used to be called *Cyclamen persicum odoratum*, but the delicately sweet perfume is very rarely to be met with now.

There is no firm that has been more successful with this flower than that of Messrs. Sutton & Sons, Reading, and the beautiful collection at Godinton Park is from their strain. We used to be satisfied with having our Cyclamens in March and April, but now we get them long before Christmas, and at the time of my visit in the early part of December a long house was filled with about 300 plants carrying about 2000 expanded blooms with plenty of buds to give a succession. Mr. Frost says that he sowed Giant White, Giant Crimson, and Giant Crimson White, and late in February, 1895, some of the plants from that sowing measured 16 inches across with three or four dozen flowers out at once. "My second sowing," he says, "was in February, 1896. It was owing to unavoidable circumstances that I sowed so late as February; the time I prefer for sowing is October, and the plants so raised flower in about twelve months time." This second sowing consisted mainly of Sutton's Vulcan, Butterfly, and Salmon Queen.

He says the culture of the plants is none of the easiest. "I find good loam (which we can get at Godinton), leaf soil, burnt earth or rather wood ashes, Bedfordshire sand, and artificial manure answer for their potting material. We drain the pots well and carefully, also look well after the watering of the plants

in the various stages of their growth, never allowing them to get too wet or too dry. Shading is another great point in their culture; they like a strong light but no sun, plenty of ventilation when in the frames—in fact, we take off the lights in the evening that they may receive the dews, and we make a point of syringing them lightly three or four times a day in the summer when it is very hot. Cleanliness is another great point; we never allow any green fly or thrips, which unfortunately they are liable to, to have any quarter. We give the plants weak liquid manure as soon as the pots are full of roots, and keep on all through the time of their flowering. We keep our Cyclamen house at 45° to 50° by night, and about 55° in the day. Some of our giant flowers measure 2 to 3 inches deep."

I may add to this that one peculiarity about Cyclamens is the one alluded to by Mr. Frost—that they come remarkably true from seeds, showing, I suppose, that they are not hybridised with any other Cyclamen species, but that the varieties now cultivated have been gained by careful selection; thus, for instance, the last valuable addition, the beautiful salmon-coloured variety of Messrs. Sutton, is obtained from a plant which exhibited a tendency to that colour. Another noticeable thing is that the very dark crimson variety Vulcan does not attain anything like the size of the others, nor does it seed so freely. Whether this will be overcome in time it is impossible to say, for, indeed, the progress that has been made hitherto seems to make nothing impossible.

I am, of course, aware that results such as these I have recorded are to be seen in many a nursery establishment, but they are not common in private gardens, especially at the season of the year in which these were found in full flower. We have always associated them with spring flowers, but I think their value is increased when they can be brought to gladden our eyes in midwinter.—*D., Deal.*

PRECEPT AND PRACTICE.

(Continued from page 48.)

"DON'T be inquisitive" was an extingisher frequently applied in my juvenile days to snuff out those sparks of desire for information most boys have who are interested in their work. We need not, do not I think, rake up these embers of the past in a purposeless manner. They have burned sufficiently deep to leave an impression upon us old boys, from which has sprung the desire, now a prominent feature in the *Journal of Horticulture*, to fan the spark into a flame instead of quenching it. Somehow a boy who loves plants has an inordinate desire to find out their names, deriving satisfaction in ratio to their length, or in the difficulty of spelling them. Inordinate I say, it was regarded so then, or why was I led astray when not tripped up in tracking knowledge to its root? Faults on both sides probably, for I may have been—yes, I believe I was—something of a young prig in chattering of how much I knew, not then knowing that every page of our knowledge is but the introduction to volumes where "Finis" finds no place.

Will you, youngest of young brothers, accept the above as a truth and digest the moral? It may, too, save you some painful touches in tender spots. The early troubles of life are very real at the time, however much matured age can afford to smile upon them. My self-imposed task was to learn the names of six plants every day, facilities for which were afforded by copious labelling at this place—my entrance to the gardening world. Difficulties surrounded the start in the pronunciation, proceeding chiefly from the failing above described, by bringing down the weight of ridicule so unpleasant a burden to the sensitive youth. In that garden *Lomaria chilensis* was long known as the Lo! Maria, my unfortunate pronunciation in displaying the profundity (?) of my knowledge. Youthful indiscretion also left an opening for the insertion of such gratuitous information by my teachers as that Rowland's Macassar oil was good for Maidenhair Ferns, and other equally choice elixirs entered into the mysteries of culture.

However, there are happier recollections of this baptism into the gardening world; and what a beautiful world it was in that little corner of sunny Kent, and what an unlimited fund of interest those hard names yielded as time lifted the mists of ignorance. Writing then a fair boyish hand, it was requisitioned during spells of potting to assist in the labelling; a most delightful task, but requiring ample elbow room, and accompanied by all those facial contortions which follow the movements of a boy's hand. But I was soon laughed out of that, and eventually learned to write my

labels rapidly and neatly in a standing position. Now, little chaps, all this chatter is not without a purpose; I want you to practise the same method instead of having to clear the decks for so simple an action. Practise writing labels by holding them in your left hand steadied against the breast, and I trust that you may now and again be permitted by your masters to exercise your hand in labelling.

On this question there is another little matter worth mentioning—viz., there is often too much disparity in a boy's writing as practised with the pencil and with the pen, the former being apt to have a monopoly, to the detriment of the latter. So much may this be the case that I have noted results almost parallel with that of Mr. Toodle's (in "Dombey and Son"), who could write "with chalk." The best illustration I can give you of this is by openly confessing that a master in after years who gave my pencil work in the way of labelling high praise, was so disappointed with a specimen of my penmanship, which he wished to submit for higher inspection, that a pencil-written paper was substituted for it. It should not have been so, considering that on many a winter's night in the bothy I have written for three hours at a stretch, but the fact remained that too often the pencil had been substituted for the pen, hence the evil pointed out for you to avoid.

Times are not what they were when I was a boy. You may be inquisitive now, must be in fact, but neither ostentatiously nor objectionably so. There is nothing that you have to do, or nothing that is done, without a reason. Do not be satisfied with doing your work mechanically, even though you do it well, and in everything endeavour to trace the effect to the cause—that is keep asking the reason why. But do not misconstrue this advice so that you are turned into a veritable little torment. Ask yourself, and probably five questions out of six will upon a little reflection and observation discover themselves to you, whilst the sixth may be settled satisfactorily by seeking at an opportune time for such information as few right-thinking men will deny you.

After the novelty of early duties has worn off a little contempt may arise of some jobs which are legitimately a boy's work. Washing pots, cleaning up the stokeholes, scrubbing out the houses, you may possibly regard as rather mean kind of work. It is not so unless you make it so; if you wash, and clean, and scrub to perfection—Napoleon could not have done more respecting his work, and did not, in fact, always do as much. There is no work even of the humblest kind but which if conscientiously performed is dignified, and confers its dignity upon the worker. Endeavour to feel that this is so, and I trust your endeavours will be rewarded by such encouragement as will leave no doubt in your mind upon the matter.

Presuming that, even at this early stage of a gardener's life, there is no intention of turning back, and taking it for granted that any sufficiently interested to follow these humble efforts on their behalf will certainly not do so, we will now "zigzag" in some practical matters; but it must be understood for once and for all that once started you will—you must—continue with such aids and material for the purpose as the daily duties and leisure hours afford. If I can show to you the ocean of knowledge your thirst should prompt you to keep yourself to the "illimitable," for, as Emerson says, "Welcome ever more to gods and men is the self-helping man." In the matter of plant names, which present some little difficulty, so apparently impenetrable are they upon the surface, we may well here break ground.

Florists' designations need not claim our attention, there being but little danger of your not becoming sufficiently conversant with them in the different phases as opportunity occurs; and as Mrs. Pollock, John Hopper, or the various Glories and Perfections, with other distinguishing or distinguished names fulfilling their purpose, it would be purposeless to dwell upon them, but do endeavour to spell and to pronounce them correctly. Those which have the flavour of a foreign tongue will doubtless as time goes on be more or less familiar to you, but it is sincerely hoped that a Gloire de Dijon will not be a "Glory de John" to you, as it was to an old friend to the end of the chapter. Knowing, as you know, that Dijon is a town in France the rest is sufficiently clear, but you may not know enough French to set yourself up on that pedestal of conceit a comrade of mine mounted to declaim that "Pomme de terre meant Pomme de tater, and anybody could parlyvoo that." Seriously I wish I could invite you to study that elegant language, but as gardeners it behoves us to dig for Latin roots. "Dry old roots too," you will say; well, we will sample a few, which will, I trust, create an appetite for more. Here are some I tasted at your age and found them to be not unpleasant.

Selecting six fairly easy names relating to form—viz., round, angular, pyramidal, long, large, dwarf, and taking them in the order of sequence, the following plants should show their right to the names they bear: *Campanula rotundifolia*, round-leaved; *Passiflora quadrangularis*, quadrangular—four-angled stems; *Campanula pyramidalis*, pyramid shaped; *Pteris longifolia*, long-leaved

(comparatively, see note to come); with *Achimenes longiflora*, long flowered; *Odontoglossum grande*, large; *Asparagus plumosus nanus*—plumosus, feathery; nanus, dwarf. These names clearly convey the character of the plant they are appended to, as do many others which you will gradually become acquainted with. Others there are which do so in a more remote degree, while again there are some members of the different families which beyond the family name they bear display no more character apparently in their distinguishing appellations than we ourselves do, but have, perhaps, the advantage over the human family by its being the means of more distinct recognition.

To prevent a confusion of ideas on this phase of the subject you will bear in mind that descriptive names expressive of size are comparative—viz., used relatively to the family or section of the family to which they belong; thus a giant of one tribe is by comparison but the dwarf to another; for instance, *Ferula gigantea*,

FIG. 23.—*BRODIAEA HOWELLI LILACINA*.

the Giant Fennel, has no affinity in size with *Wellingtonia gigantea*, but each are representative of their types, although the latter is restricted at present to the one member with its varietal sports. Similar simple revelations concerning plant names relating to colour and habit will next be broached; plain enough, I hope, for you—my youngest reader—to take up the matter at once, that it may go hand-in-hand with daily work and nightly recreation, for—

"Are you in earnest? Seize this very minute;
What you can do, or think you can, Begin it."

—AN OLD BOY.

(To be continued.)

BRODIAEA HOWELLI LILACINA.

THE several species and varieties of the *Brodiaeas* are well known to all our readers as flowering plants of much beauty and considerable utility. Some of them are comparatively scarce, whilst others are abundant, and consequently cheap. One of the newest, *B. Howelli lilacina*, is depicted in the woodcut (fig. 23), and was shown by Messrs. R. Wallace & Co., Colchester, at one of the summer meetings of the Royal Horticultural Society last summer. So beautiful and distinct was the variety considered that the Floral Committee recommended a first-class certificate. The form of the flowers is shown in the woodcut, and in this alone the difference from the type is readily discernible. The lower portion or tube of the flower is bright lilac in colour, while the upper portion is pure white.

TUBEROUS ROOTED BEGONIAS FROM SEED.

THE value of tuberous Begonias, both as greenhouse decorative plants and bedding plants, is now fully recognised. Both the double and single varieties are equally useful for either purpose. The doubles, perhaps, find the most favour, because the individual blooms are compact, bright in colour, and attractive. For button-hole flowers the double varieties are hard to surpass, and are frequently grown for furnishing neat and effective flowers for this purpose, as well as affording decorative plants of the highest value. The single varieties produce very large flowers. Good plants of a floriferous character and bushy habit are showy and effective for a considerable period during the summer months in the greenhouse. Among them there is a wide range of colour, including shades of white, blush, yellow, crimson, and red.

Both erect and drooping growers are found among Begonias. The erect growing varieties are obviously the best for pot culture; the drooping for baskets, which may be suspended from the greenhouse roof. With good cultivation and attention in affording due supplies of moisture to the roots during dry weather luxuriant growth will be made. The growths and blooms depend from the baskets in a most graceful manner.

A collection of Begonias is interesting as regards the foliage, which varies in shape and hue, also markings, which render the plants attractive in this way. The more freely the plants grow, provided the growth is made under favourable conditions, the better they flower, as blooms are continually being produced from the new growths. Tuberous Begonias are essentially summer-blooming plants, and by no means can they be made to bloom during winter, or to grow and flower continuously.

RAISING PLANTS FROM SEED.—There is little difficulty in securing a collection of good varieties in a wide range of colour and form by raising plants from seed. The seed is extremely small and requires extraordinary care in sowing, so that by no mishap shall the tiny pinch of dust-like particles be lost in the process of transferring them from the 1s. 6d., 2s. 6d., 3s. 6d., or 5s. packet to the surface of the seed pot or pan. Small seeds like Begonias must have specially prepared surfaces on which to germinate readily and grow freely. Procure clean dry pots 5 or 6 inches in diameter, or shallow pans of larger area. The pots should be half filled with drainage, the pans not needing quite so deep a layer of potsherds or crocks. Keep the drainage clear of soil by a protecting layer of damp moss, or fibre from the compost; on this place the prepared material for sowing the seed upon. This must consist of sweet ingredients—equal parts of fibrous sandy loam, decomposed leaf soil and silver sand, thoroughly well mixed.

In order that the compost may be known to be absolutely free from insects or worms the whole prepared material ought to be scorched on a hot plate or shovel. After this process moisten the compost with sprinklings of warm water, mixing to a pleasantly moist condition. It will then be ready for use. Place it in the receptacles fairly firm, and level the surface with something smooth. It is desirable to still further moisten the compost by standing the pot or pan in tepid water until some begins to rise through the surface, but before this becomes evenly wet, withdraw and allow the soil to drain.

I ought to have stated previously that the material must be riddled fine, especially so on the surface where the seed has to rest. Scatter the seeds evenly. If any attempt is made to cover them, the slightest film possible of sand only should be applied. The seed frequently germinates well without any covering of soil. Cover the pot or pan with a sheet of glass to prevent evaporation, and over that lay paper or moss to darken the soil. The next point is the selection of the position for placing the seed receptacles. Both top and bottom heat is requisite to command success. The best place is a propagating frame in a forcing house or stove where a constant temperature of 65° to 70° is maintained.

Moist surroundings, too, are imperative. Any undue drying of the pots or soil may jeopardise the process of germination. The temperature named just affords that gentle stimulus which causes activity, and in the course of a few weeks if the temperature is regularly maintained many young plants will appear. Not all, however, will do so as early as this, but in due course a large percentage ought to germinate. If moisture condenses too freely on the glass at any period wipe it dry.

The darkening material must be removed immediately the first seedlings appear, but the glass may be kept over the pots or pans until the tiny plants acquire some strength, when it may be gradually removed. The seedlings require pricking out into fresh compost long before they are of sufficient size to handle with the thumb and finger. Their removal, however, may be managed by means of a small notched stick inserted under them to lift them out and place them an inch apart in pans of similar compost. Still afford them the same temperature and moisture.

Cocoa-nut fibre affords a suitable medium for rendering a moist base on which to place the pots and pans. It is easily damped, and readily allows heat to pass through it; but any of this material in contact with the hot-water pipes soon dries. In a measure it then prevents the heat ascending, so this portion must be specially looked to.

Very light sprinklings of water are necessary when the seedlings are first spaced out; but as they grow more may be given with good results, also light and air in proportion, following with an introduction to a cooler temperature preparatory to potting into small pots, shifting on as required until a flowering size is reached. Good plants from seed raised now may be had in flower in autumn, but any tubers that do not attain strength and size enough to flower this season make fine plants the following year.—E. D. S.

CHEMISTRY IN THE GARDEN.

(Continued from page 76.)

SULPHUR (symbol S).—This element is a brittle, solid substance, of a lemon yellow colour. It is found in a free state in nature, and also in combination, in a variety of forms, with other elements. Sulphur is found in a free state in many parts of the world, particularly in those districts where volcanic action is going on. Sulphur combines chemically with oxygen in several different proportions, but the following is the only form we need consider:—One part of sulphur united with three parts of oxygen. This substance is called sulphur trioxide (SO_3), and when combined with one part of water forms sulphuric acid (H_2SO_4). This acid combines readily with alkaline and other bases (e.g., potash, ammonia, lime, or iron) to form sulphates, good examples being sulphates of potash, ammonia, lime, and iron; and it is from one or the other of these substances that plants obtain their sulphur.

PHOSPHORUS (symbol P).—This element is never found in nature in a free state. It can be prepared, however, from compounds containing it, when it has the appearance of a colourless transparent solid substance. Combined with other elements phosphorus is one of the most widely diffused of all the elements.

Phosphorus combines readily with oxygen and hydrogen to form phosphoric acid ($\text{H}_3\text{P}_2\text{O}_8$). From its chemical formula we see that one part of this acid consists of six parts of hydrogen, two parts of phosphorus, and eight parts of oxygen. The acid combines with bases like lime, magnesia, and iron to form phosphates of lime, magnesia, and iron; and these are the forms in which it exists in soils. The amount of phosphoric acid in many soils is very small, and even the most fertile do not contain very large quantities. Phosphorus is taken from the soil by plants, principally in the form of soluble phosphate of lime; and the element is found in them chiefly in the albuminoids and seeds.

POTASSIUM (symbol K).—This element is a soft white metal slightly tinged with pink. It is never found in a free state in nature, but occurs in large quantities in combination with other elements. Potassium unites readily with oxygen to form potash (K_2O), and with oxygen and hydrogen to form caustic potash (KHO). Potash forms one of the alkaline bases, and will therefore combine with acids to form salts. The potash salts are found very widely diffused in nature, some of them (silicates and nitrate of potash) being present in soils, while others occur (sulphate and chloride of potash) in some saline deposits and in sea water.

Potash is found in plants in combination with organic acids. Its use in the plant seems to be to help in the formation of starch, and it is absorbed from the soil chiefly in the form of sulphate and nitrate of potash.

MAGNESIUM (symbol Mg).—This element is a silver-white metal, never found in nature in a free state, but always in combination with other elements. If magnesium wire be strongly heated it takes fire and burns, emitting a brilliant white light, and falls down as a white powder. This powder is magnesia (MgO), an oxide of magnesium, and is formed by the chemical union of oxygen gas from the atmosphere with the metal. Magnesium is found in nature principally in combination with carbonic acid, as carbonate of magnesia, but it also occurs to a lesser extent as silicate, nitrate, chloride, and sulphate of magnesia. Plants do not require a very large amount of this element for their development, and all they need of it is absorbed from the soil either as nitrate, sulphate, or chloride of magnesia.

CALCIUM (symbol Ca).—This element is a soft yellowish coloured metal, never found in nature in a free state. When one part of calcium unites with one part of oxygen it forms the substance known as lime (CaO). Lime combined with carbonic acid forms carbonate of lime (CaCO_3), and this compound occurs in Nature to such an extent as to form no less than one sixth of the rock surface of the earth's crust.

Nitrate, sulphate, carbonate, phosphate, and silicate of lime are the forms in which lime is found in the soil, and the first, second, and fourth of those compounds are the sources from which plants obtain their supply. The function of lime in plants is not quite understood, but it seems to act chiefly as a carrier of nitrogen, sulphur, and phosphorus into them. It afterwards combines with the organic acids (*e.g.*, oxalic acid) formed in the plants, and neutralises them, thereby making them harmless.

IRON (symbol Fe).—This element is found widely diffused in nature in a free and combined state. It occurs in soils as iron oxides, carbonates, phosphates, and sulphates. The green colouring matter of leaves (chlorophyll) cannot be formed unless iron be present, and in the absence of this element the leaves of plants only assume a white or yellowish colour.

SODIUM (symbol Na).—This element is a silver-white metal, never found in a free state in nature, but occurs in large quantities in combination with chlorine, as rock salt. Sodium unites with oxygen to form the compound soda (Na_2O), and this substance forms one of the bases, consequently will combine readily with acids to form salts. We have good examples of the sodium salts in nitrate and phosphate of soda, both valuable fertilisers. Although soda is always found in the ash of plants, it is not considered essential for their growth, for they have been grown successfully in water and sand to which not a trace of this element was applied.

CHLORINE (symbol Cl).—This element is a yellowish green gas, possessing a pungent odour. It is never found in nature in a free state, but as chlorides of soda, lime, magnesia, or potash it is found almost universally distributed. Some plants have been grown successfully without the aid of compounds containing chlorine, but it has been found to be necessary to apply it to others.

SILICON (symbol Si; weight 29).—This element, although the most abundant in nature, is never found in a free state. It is found united with oxygen as silica (SiO_2) in large quantities. Silica is found in a nearly pure state in quartz sand, in flints, and in rock crystals. Plants can be grown without the aid of this compound, although it exists in large quantities in the straw of Wheat, and in stems of the Equisetum.

ALUMINUM (symbol Al; weight 27).—This element is a white metal, and united with oxygen forms the substance known as alumina (Al_2O_3). Although this element is not a constituent of plants, it is, like silicon, a very important ingredient of soils. Pure clay is composed of alumina, silica, and water chemically combined; but we shall deal more fully with this element and silicon when we come to consider the composition of soils. The weights of the last two elements were omitted from the table, but are now given.—W. D.

(To be continued.)

I HAILED with delight the article headed "Chemistry in the Garden," but when I came to the last paragraph on page 47, I said, This seems wrong. "W. D." says, "The reason of this is that during growth certain chemical changes are taking place, during which oxygen is absorbed and carbon dioxide exhaled." Is this so? Should it not rather be CO_2 is absorbed, and oxygen exhaled?

I was once told by a head gardener that to become proficient I ought to be able to analyse the ash of a plant to see what elements went to build up its tissues; the result was I joined chemistry and botany classes. The teacher, a professor of chemistry, told us amongst other things that plants took in carbon dioxide (CO_2) the CO_2 was split up, the carbon was assimilated by the plant, and the oxygen given off; that animals on the contrary took in oxygen, part of which combined with the superfluous carbon, and was given off again as CO_2 . This seems just the opposite of what "W. D." says.

On turning to "Oliver's Botany," p. 14, par. 7, he says, "With regard to the important element carbon experiments clearly show that it is absorbed in combination with oxygen as carbonic acid gas. . . . The green-coloured organs of plants, under the influence of sunlight possess the power of abstracting it directly from the air. Par. 8. But the most remarkable circumstance attending this absorption of carbonic acid gas is the liberation of oxygen gas by the leaves. . . . This fixation of carbon, and liberation of the oxygen of carbonic acid gas has been termed vegetable respiration; but as the conditions which obtain are the reverse of those characteristic of animal respiration, it may be more correctly spoken of as characterising the process of vegetable assimilation." I should like to know what "W. D." has to say further on the subject. I believe that chemistry, if well understood and practically applied to gardening, is one of the great helps to success.—HENRI.

VISITORS TO KEW GARDENS DURING 1896.—The number of persons who visited the Royal Gardens during the year 1896 was 1,396,875. That for 1895 was 1,407,369. The average for 1886-95 was 1,425,526. The total number on Sundays was 536,181, and on week days 855,715. The maximum number of visitors on any one day was 86,399 on May 25th, and the smallest 62 on March 18th.—("Kew Bulletin.")

POLYANTHA AND CHINA ROSES.

POLYANTHA Roses are, I am gratified to learn, steadily increasing in popularity, nevertheless I think they should, assuredly, be more widely cultivated. They have many valuable attributes. They are easy of culture, extremely hardy in character, and vigorous in habit; they flower early and late, and produce multitudes of miniature and extremely graceful flowers. Some of this family are very fragrant, such for example is the pure white Anna Marie de Montravel, which is surely one of the sweetest Roses in existence.

For many of the finest of the Polyantha Roses we are primarily indebted to that consummate French rosarian, the late M. Guillot. From his famous Lyons rosarium came Ma Paquerette in 1875, Mignonne in 1881, and the beautiful rose-coloured Gloire de Polyantha in 1887. Dabreuil has given us two veritable gems—Etoile d'Or and Perle d'Or, of which the latter Rose, with its lovely orange centre, is perhaps the most attractive of the Polyantha race.

Of climbing varieties, whose number is as yet sufficiently circumscribed, the most valuable are undoubtedly Polyantha grandiflora, a splendid pillar Rose; and Turner's Crimson Rambler, one single truss of which produced last summer in my garden 120 flowers. One of the most valuable qualifications of this phenomenal Rose, originally brought by an engineer from Japan, is that of retaining its remarkable brightness for several weeks, especially when grown, as it is here, in a partially shaded situation. I have seen the original plant of this world-famous variety in the garden of the late Mr. Chas. Jenner, near Edinburgh. He was a brother of Sir William Jenner, the head of a great firm and a distinguished cultivator of alpine flowers.

China Roses possess, like the Polyanthas, this important qualification, that from earliest summer till latest autumn they are in constant bloom. Of these, perhaps the most highly endowed are Laurette Messimy, of most distinctive colour, raised by Guillot; Cramoisi Superieure, velvety crimson in colour, of climbing tendencies and very prolific; the "Brave Old Monthly," deservedly eulogised by Dean Hole; Mrs. Bosanquet, supposed by some rosarians to be of Bourbon origin; Laffay's Fabvier, of brilliant scarlet hue; Queen Mab and Duke of York, both valuable acquisitions for the adornment of our gardens, for which we are indebted to Mr. William Paul, whose latest introduction, Enchantress, is worthy at least of China extraction. It derives much interest, in addition to its great beauty, from its winter-flowering qualifications.—DAVID R. WILLIAMSON.

DISCOLOURATION IN POTATOES.

"W. G." has raised a very interesting question (page 76) when he deals with that form of discolouration known as blackness of flesh so often found in Potatoes. That what he refers to is not due to rough treatment or to bruises is undoubtedly true. A good deal of blackness is produced by rough usage we all know, and especially is it so with the softer fleshed or more starchy flesh of certain varieties when roughly handled. But rough usage promoting blackness of one form, whilst the effect is precisely the same, yet does not help to the elucidation of the other constitutional blackness which is referred to. I have found some curious differences in reference to soil capacities in connection with certain varieties. One, a very fine white kidney, and should have made a splendid market variety, used to boil very black in West Middlesex, which soon destroyed its reputation. Down in Berkshire it does splendidly, and is one of the most favoured varieties of the district.

What I assume, therefore, is that Potatoes, like Apples, have diverse requirements, which certain soils do not always furnish, but other soils do; hence they are good in one place and indifferent in another. What those requirements are in these certain varieties chemists alone can tell, that is if their analysis should reveal the secret. It may be deficiency of starch, or of some other essential constituent which the soil fails to create in needful quantity. Then if there be both soils that fail to provide these requirements and varieties on that soil, evidence in the blackness of their flesh that something is wanting, or may be in excess, then how useful would it be on such soils and with such varieties to test various compounds of manurial form—soot, lime, phosphate, potash, or other ingredients—that it may be ascertained whether in that way amelioration is possible or not. In these days of advanced scientific knowledge it seems incredible that a difficulty of this nature should exist without the cause being speedily ascertained. I have often noticed when attacks of disease have destroyed the leafage early that tubers, especially in the heel ends, have manifested the complained of blackness very materially. The conclusion in that case is that the tubers are deficient in starch or some other ingredient, because their leaf laboratory was so early destroyed.

No doubt the Potato does suffer more than any ordinary edible vegetables from any disease, not only because the Peronospora induces rot or disease in the tubers, but also because, through the premature destruction of the leafage, the tubers too seldom come to full maturity. That is specially so with large tubers, and an excellent reason why we

should strive to obtain tubers of medium size, well charged with starch, and making good food, rather than big ones that are so largely composed of water and imperfectly formed flesh. I think we have very much to learn even yet concerning Potatoes and their culture. So far our trials have chiefly been in relation to production. Now we seem to need tests of capacity to secure the highest quality.—A. D.

BRIEF NOTES ON ALPINE FLOWERS.

(Continued from page 8.)

THE WINTER ACONITE.

THOUGH this is not one of the choice and rare gems of the rock garden, its brightness now in the second week of January, in a low shady corner, makes it worthy of a passing note. It is sometimes seen in hot, dry positions, where it is weakened by the long period of "drying up" which it so frequently encounters in summer in such a situation. The little *Eranthis hyemalis* is one of the tuberous-rooted plants which should not be any longer out of the ground than can be helped, and also likes to have always a little moisture about it. In a low damp corner it is at home, and increases at the root, and by means of its seeds also. I do not intend to say anything about its little flowers, which are so bright and cheery when there is little else to warm up these dull corners. These flowers must speak for themselves, but this brief note may not come amiss and may induce some to give it more suitable treatment than before.

SEMPERVIVUM ARACHNOIDEUM.

This, and other "cobwebby" Houseleeks, frequently looks very unhappy in winter, especially in a wet season, and this is more noticeable when they are planted on the flat. Here they generally appear very unhappy unless growing in the crevices of the rock garden or on the face of a wall. The rain, which has so often been with us this winter, takes away the whiteness of the woolly tomentum with which the little rosettes are overspun and makes it dull looking. Not seldom do these cobwebbed Houseleeks damp off in some wet localities, where all the conditions are unfavourable. The wall is certainly the best place to grow them outside. Although the rosettes are smaller on a wall, the tomentum is whiter and the plants more healthy in their looks. A good start may be made by making a small hole in the mortar of a wall, filling it up with a mixture of clay and cow manure, and inserting in this compost the base of one or two rosettes of the Houseleek. The hole may be made so that the mouth of it shall be slightly turned upwards, so as to direct into it more of the rain that falls than it would otherwise obtain. The spring is the best season of the year for planting, and in the course of a few years the one or two rosettes originally planted will have increased into a neat little mass. This is a very good way to grow the most of the Houseleeks, all of which look very well on the face of a stone or brick wall.

SAXIFRAGA AIZOON ON A ROOF.

We often see Houseleeks and Stonecrops on roofs, but seldom any of the Saxifrages. Some species are not at all adapted for such hot and dry places, but it is wonderful to see how well the encrusted ones do on a roof, always provided of course that they are not allowed to become quite shrivelled up and scorched. A compost of stiff clay and cow manure, with a little lime rubbish among it, should be mixed with a little water, made rather firm, and put on the roof while wet. The Saxifrage may be planted in this before it becomes dry. In very dry weather the leaves sometimes becomes quite limp, and when this is seen to be the case it will be well to apply a little water by means of a syringe or hose. This will soon revive the drooping plant. A large plant of a Saxifrage, such as *aizoon*, looks very handsome on a low roof with its long, grey, strap-shaped leaves forming large rosettes, and surmounted in spring by its flowers on long stalks. One such plant on the roof of an outhouse in the writer's garden is very pretty even in this early season of the year.

FORMING ROCKERIES.

It is yet much too early to plant out alpine flowers, but not too soon to form the rockeries upon which they are to grow. Instructions in forming rockwork have been given in the Journal before, but it is difficult to impress too strongly upon those about to construct rockeries that the welfare of the plants should be considered in preference to the picturesqueness of the structures upon which they are to grow. A good body of earth free from holes and cavities is necessary. This soil ought to be good if at all obtainable. The stones must also be arranged in such a way that rain will soak through the earth, and not run off as it falls. This will not be the case if the rockery has too steep a slope, and a series of terraces on which the flowers are planted will be found very suitable for the purpose.

There are some plants which prefer to hang over stones, or to grow from a crevice, but these nearly all send roots away into the soil behind and below, which must be supplied with moisture from somewhere. There are many steep rockeries which are dust dry in summer, but in which flowers needing moisture at their roots are expected to thrive. It is almost needless to say that disappointment is certain to result should this requirement not be satisfied.

ALPINES IN FRAMES.

Rather a critical season for Alpines in frames is at hand; one may almost say is here. Air should be freely admitted unless in very hard

frost. But for being in pots, which might be rent by the frost, they would be better to have air even then. With the mild weather prevalent of late it is necessary to give air to prevent damping off. Rotting and decaying leaves ought to be taken away and a free circulation of air encouraged. Slugs may also be looked for and captured as speedily as possible, as on some plants their ravages are quite destructive. Coal ashes do not give the immunity they are said to yield. Sometimes these pests of the garden are found clinging to a piece of cinder, apparently quite comfortable upon the surface of what is placed to keep them away. The glass of the frames may be kept propped up at both back and front. If the frames admit of ventilation further down air may also be given there. Very small and weakly plants are better in a greenhouse with a little fire heat, but with plenty of air. Keep them near the glass and water carefully, keeping them slowly growing on until they can be properly hardened off before planting out in spring.

CYCLAMEN COUM.

The little space remaining for these notes may not unprofitably be devoted to the beautiful little Sowbread which bears the above name. An early form in my garden has its deep crimson flowers lifted up ready to unfold their closely packed petals. These little hardy Cyclamens are always much admired, although their flowers look tiny beside those of the best of the Persian Sowbreads. The admirer of alpine flowers can hardly help having an affection for these little plants with their round flattened tubers, round leaves, and beautifully formed and coloured flowers. There is not space to tell much more about this Cyclamen. It likes a sheltered but shady spot, and appreciates the partial shade of trees or dwarf shrubs. A little limestone or old mortar rubbish mixed with rich loam, or even sandy peat made firm, is not unwelcome to it.

It is, perhaps, safer to purchase plants of these in small pots, out of which they can be turned with the earth attached. The leading growers of hardy plants for sale keep them in stock in these pots, and there is less danger of losing them when thus obtained than if lifted from the open ground. C. Coum may also be grown from seeds, which should be sown as soon as ripe if they can be obtained. A few established plants will soon produce self-sown seedlings. The final words of this note must be:—"This is a charming little plant, worthy of care on account of its beauty."—ALPINUS.

(To be continued.)

WINTER WORK.

IN a note on the present severe weather we are experiencing, an esteemed contributor says "gardening operations are at a standstill." Never in my experience, which may be allowed to date from the time I went "Covent gardening" as a small boy in knickers, has it been my lot to participate in such a dead state of affairs as that indicated. The work of the ground, such as digging, may be temporarily stopped, but gardeners, as a rule, know in how many other ways their energies may be exercised. It is to be hoped in any case that with the advent of frost and snow the community at large do not believe that means the departure of work from any number of gardens.

I have jotted down a few things which may be worthy of mention in the Journal, and that may with advantage be proceeded with at the present time. We are at present busy clearing dead wood from shrub-berries, also pruning shrubs that are growing into each other, and where snow does not lie thickly giving a good clean out. Wheeling should, as much as possible, be proceeded with now; rubbish fires may be kept going, snow will require to be swept, pea sticks as they come to hand sorted over and pointed, and pegs made for use later on. Such work done now will save much valuable time in the summer.

Where labels are not bought they may now be made and tied in bundles according to the various sizes. Stakes for herbaceous plants in borders should be looked to, those worn out put on one side for firewood and new ones pointed and tied in bundles ready for use. Boxes for propagation and seed sowing may be made; sometimes frame lights are at liberty and may be taken under cover, when a handy man will paint and repair them where necessary. Manure should be obtained, turned, and got ready in preparation for hotbeds. The humble but useful art of pot-washing may now be practised in warm water.

In the middle of the day we have proceeded for a few hours with the pruning and nailing of Peaches and Nectarines, but we do not advocate this work to be done in very cold weather, as it is next to an impossibility to do it as well as is desirable. All these things, however, got well in hand now, will prove helpful hereafter when the pressure comes and work crowds on us faster almost than is in our power to cope with.

Extraneous help will in a number of cases be brought to bear on work under glass, such as limewashing, glass washing, winter dressing, the preparation of soils which have been placed under cover. There may be ice wells to fill, with all the work that this operation involves; but enough has been said to show that if we have no digging there need be no dearth or cessation of work simply because we are having a spell of wintry weather, and if our "Standstill" friend were at my disposal I could find him plenty of exercise.—A BUSY BEE.

IRIS.—Where there is a large demand for flowers Irises will be found most useful if only taken up and placed in early vinery or Peach houses, but if for conservatory work they will repay extra care by potting them. Their Orchid-like flowers predominating above other flowers form a feature for Eastertide if taken up at once.—A. E.

HINTS ON FORCING.

(Continued from page 53.)

THE various sections of hardy Azaleas each contain many varieties well adapted for forcing; indeed, they include some of the most showy plants that can be brought into flower during the depth of winter. In the numerous varieties of *A. mollis* we have, I think, the type best suited for forcing, as the flowers are of good shape, the trusses large, and the habit of the plants good. Although I am a great lover of the Belgian and Pontica varieties when grown in the open air, for forcing the mollis section is gradually superseding them, principally on account of their larger flowers and more compact habit of growth. The plants should be obtained as early as possible in the autumn, and after being potted plunged in ashes in the open air; then, if not introduced into heat till Christmas, they usually give a good account of themselves. The earliest batches I like to plunge in a little bottom heat, and syringe freely each day to induce the whole of the buds to open simultaneously.

With the best of attention, however, a few flowers will sometimes open greatly in advance of the majority on a given plant. When such is the case I use these early flowers in a cut state. Those left then usually open together, and are sufficiently numerous to make the plant attractive enough to place singly in a vase. By the time the flowers are beginning to show colour we often get bright bursts of sunshine, which cause them to flag badly. An inexperienced attendant is then tempted to give water freely at the roots, which often aggravates the evil. The right course to adopt is to damp between the pots with a syringe, and give temporary shade till it can be clearly ascertained whether or not the plant is in need of water. With this treatment well developed flower trusses may be obtained, when without such attention they would lack substance and drop quickly.

Amœna, and the improved type *A. splendens*, are good evergreen varieties that should be grown in quantity for early forcing; these succeed the best when kept in pots throughout the year.

Deutzia gracilis, although an old favourite, is still one of the very best shrubs for forcing, bearing white flowers. Mistakes are, however, frequently made in its culture. A common one is to pot the plants in the autumn only a few weeks before they are taken into heat. The result of this practice is that many of the flower buds turn yellow and drop, and the plants show great signs of distress if a little air is admitted into the house or pit in which they are growing, or if a few gleams of sunshine reach them. Shoots with flowers and leaves of this description are practically useless when cut; they have no lasting qualities. The way to avoid such mistakes is to grow the plants intended for early forcing in pots throughout the year. Then if given liberal treatment during the summer good firm shoots are produced, which will stand sharp forcing, and flower at every joint, because there are plenty of active roots to support the young growth as it develops. The main batch should be potted from the open ground in September before the leaves have fallen. The plants then have time to recover themselves, if not to form new roots, before they feel the strain of forcing.

Forced Lilac seems to become more popular each year, and in large establishments, when cut flowers are in great demand, it behoves the gardener in charge to work upon a good system in the endeavour to provide a supply. As in the case of *Deutzia gracilis*, an early batch should be grown in pots, so as to secure plenty of healthy roots ready to spring into activity when the plants are introduced to heat. Later bushes may be planted in the open air, and potted early in the autumn. When these have done flowering the shoots should be cut back to within 2 inches of their base, grown for a time under glass, and in April or May planted in the open air again, and allowed to remain there for eighteen months before being forced again. In forcing the earlier plants it is a good plan to place them in a Mushroom house or other structure which can be darkened, and in which a temperature of from 55° to 65° can be maintained.

A cellar will answer the purpose if sufficient fermenting materials are introduced to keep up the necessary temperature. Under this treatment the flowers of the common varieties will come perfectly white, but few if any leaves will be produced at the same time. This difficulty can, however, be overcome by placing in a forcing house a few bushes not furnished with flower buds shortly after the first plants are introduced into a darkened structure. The present is an excellent time to place a good batch in forcing houses, where a temperature of from 65° to 75° is maintained. If placed under the stage where light is partially excluded the flowers come white, and leaves are produced at the same time.

It does not answer, however, to pursue this plan in November, because at that season if plants are placed at the outset in so high a temperature strong growth is quickly produced, and the flower buds become hard and refuse to break. Every part of the plants should be syringed twice daily while growing in forcing houses at this season when high temperatures are maintained. Those who have not a supply of plants on hand can easily obtain them from any nurseryman of repute. Charles X. is the variety most largely used for forcing, but the common one answers the purpose very well. The new varieties now being sent out will in time supersede these, but at present they are rather too expensive for forcing largely.

A hint worth knowing about this forced Lilac is that if a strip of bark 2 inches in length is removed from the base of each shoot, immediately before placing it in water, the freshness of the flower will be preserved for a very much longer period than would be the case if only the end of the shoot was cut off.

The common Sweet Briar does not seem to be forced so largely as formerly, yet wherever its deliciously scented shoots are produced they are always appreciated. The right course to adopt is to lift the plants and pot early in the autumn, then plunge them in ashes till November or December, when they can be introduced to heat as required. At this season of the year, however, I have frequently lifted plants from the reserve garden and taken them directly to the forcing house with satisfactory results. One often omits to pot such things as these at the most seasonable time; it is, therefore, fortunate that it is not too late to do so now, and in the course of a few weeks be rewarded with shoots bearing tender sweetly scented leaves at a time when suitable greenery for arranging with cut flowers is generally scarce.

Solomon's Seal (*Polygonatum multiflorum*) is another extremely useful plant for forcing, as its long shoots, delicate leaves, and drooping white bells are of a type always welcomed by those who are constantly arranging cut flowers. An excellent way to force them is to lift the roots as required, pack them closely in boxes a foot in depth, work in a little soil among the roots, water, and cover the box with a board. The box can then be placed in a forcing house, vinery, or any other structure where room can be found, and the board be removed when a few inches of growth have been made. Treated in this way, a good length of stem is secured. As soon as the principal shoots have been cut the plants can be gradually hardened, and in April divided and planted in a prepared bed in the open air, where it is necessary to leave them about three years before they are lifted again.

I always make a point of growing a few plants of *Rhododendron Nobleanum* in pots continually, as they may with very little forcing be had in flower early in February. They must, however, be well attended to during the summer months, or only puny flowers will be produced. The older varieties have flowers of scarlet, rose, and light pink shades of colour; but there is a fine new addition named *N. coccineum*, which produces flowers of a very bright and attractive scarlet. I hope to conclude these hints next week by a note on Roses.—PLANTSMAN.

MANURE FOR TOMATOES.

HAVING last season suffered from various fungoid diseases in my Tomato houses, I have, in addition to taking in fresh soil, mixed with it a good dressing of lime; but as I think the soil will need some enrichment, would it be advisable to use some kainit previous to setting out plants? I wish to avoid altogether the use of stable or farmyard manure, as I am inclined to think this very often causes fungoid attacks. Advice will be greatly esteemed.—T. P. R.

[In order to have full and properly swelled crops of Tomatoes, something more than fresh soil, except it be unusually rich and lime mixed with it, will be necessary. The Tomato requires a good all-round food, as shown by the constituents of the ash of the plant in parts per hundred:

Potash	27.00
Soda	10.39
Lime	12.16
Magnesia	8.21
Iron	3.96
Phosphoric acid	18.58
Sulphuric acid	4.86
Silica	12.36
Chlorine	2.54

100.00

Nitrogen 2.31

Kainit would supply the requisite potash, soda, magnesia, and chlorine; superphosphate, the essential phosphoric acid, with some sulphur (sulphate of lime); sulphate of iron, the available iron required; either sulphate of ammonia or nitrate of soda, the imperative element nitrogen. It is therefore a question of proportions of the substances named, and the following is an excellent and economical formula:—

Dissolved raw bones	6	parts or lbs.
Kainit	6	" "
Sulphate of ammonia	2½	" "
Sulphate of iron	½	" "
Gypsum	5	" "
						20	" "

Mix and apply 4 ozs. per square yard, or 7½ lbs. per rod. If the soil be poor double quantity may be used, pointing-in well with a fork. This is a substantial food, as the substances come into availability gradually, and are safeguarded against loss. If the soil is light, the following simple mixture at a low cost gives excellent results:—

Fish meal ("white fish")	10	parts or lbs.
Mineral superphosphate	2½	" "
Kainit	5	" "
Nitrate of soda	2½	" "
						20	" "

Mix and apply 4 ozs. per square yard, or 7½ lbs. per rod, and point-in shortly before planting.]

WEATHER IN LONDON.—The weather in London has undergone a great change since our last issue went to press. Then we were in the midst of frost and snow, and now we are enveloped in fog and small rain. On Friday last the thaw commenced and rapidly proceeded until there were no remaining signs of frost and snow. On Tuesday rain fell incessantly, while in the southern suburbs there was a fog of the pea soup variety in the early morning. There was a very slight frost on Wednesday morning.

WEATHER IN THE NORTH.—For the past week the frost has not been so intense, averaging about 6°. The feature of the week has been the general snowstorm towards the close of it, Saturday's fall being especially heavy, resulting in blocked roads and railway lines in the northern counties, and the isolation of towns here and there. Tuesday morning showed 2° frost, with indications of more snow. —B. D., *S. Perthshire*.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will take place in the Drill Hall, Victoria Street, on Tuesday, February 9th. The various Committees will assemble at noon, as usual, and at three o'clock the annual general meeting of the Society will be held at the Society's Offices, 117, Victoria Street, Westminster.

A GREAT FORTHCOMING FÊTE.—A happy movement in connection with the long reign celebrations is the Imperial Fête in aid of the Victoria Hospital for Children, to be held in the Botanic Society's Gardens next June. The fête is receiving hearty support on all hands. The Prince and Princess of Wales and other members of the Royal family are taking a deep interest in it as patrons of the undertaking, and the whole of the Botanic Gardens have been placed at the Committee's disposal.

ILEX AQUIFOLIUM LAURIFOLIUM LONGIFOLIUM.—Of the many varieties of the common Holly in cultivation in our gardens, this is certainly one of the best. When planted in good soil it is of rapid growth, and forms a somewhat close-growing pyramid. The leaves are ovately oblong, narrowing at the apex to a spine. They average 5 inches in length by 2 inches in width, colour dark green and very glossy. Many of the leaves are quite destitute of spines, with the exception of the small one at the apex; other leaves have spines on the margins, ranging in number from one to eight. The berries are large and bright red. The free growth of this variety, together with its large, distinct foliage and good habit, should make it a very popular subject for ornamental planting as it becomes better known. Another variety, known as *I. aq. camelliaefolia*, is very similar; in fact, almost identical with the foregoing. —W. D.

THE RETIREMENT OF MR. DAVID THOMSON.—A wide circle of friends will learn with deep regret that Mr. David Thomson, Drumlanrig Castle Gardens, is soon to vacate the post of head gardener to His Grace the Duke of Buccleuch, and to retire from that responsible position next May, which he has held with such distinction for twenty-nine years. Mr. Thomson's successful career as a horticulturist, and manager of the princely gardens indicated, also at Archerfield and in England, is well and widely known to all who have seen the work which he has accomplished during a most active and exemplary life. In every branch great achievements have been made by his masterly skill. The urbanity, kindness, and high character of Mr. Thomson, his help and communicativeness to all who sought his advice on many matters of importance, as well as on gardening, has commanded the esteem of very many friends. Mr. Thomson has, with great lucidity on every branch of horticulture, written much which is greatly appreciated by many readers. His noble employers feel keenly the severance of their valued manager from their splendid domain, and have made many kindly overtures to Mr. Thomson to remain at his post. Though his activity of body and mind is much in evidence, the health and advancing years of the worthy veteran have now to be considered. Mr. David Inglis, head gardener to Lord Grey, Howick Hall, Lesbury, has been appointed successor to Mr. Thomson. This very able all-round gardener (now in the prime of life) well merits the choice which has been made.

MR. HUGH FRASER.—We learn that Mr. Hugh Fraser is about to retire from the service of Messrs. Methven & Sons, nurserymen, through failing health. Mr. Fraser has been with this firm during the last forty-eight years, and as a member of the Edinburgh Naturalists' Field Club and Microscopical Society, the Edinburgh Botanical Society, and the Scottish Horticultural Association, is widely known and respected.

SUDDEN DEATH OF LORD LEIGH'S GARDENER.—Widespread regret is felt in the neighbourhood of Kenilworth and Warwick at the sudden death of Mr. T. Beddard, which took place on the morning of January 24th, and was due to heart disease. The deceased gardener held for nearly twenty years the important position of chief in the management of the extensive and well kept gardens at Stoneleigh Abbey. He was highly esteemed by the noble family he served so faithfully, and his courteous uprightness and kindness of heart secured for him a host of friends among the many thousands of visitors to Stoneleigh. As a gardener he stood in the front rank, and his untimely death will be greatly regretted by his many friends in the horticultural world. —H. D.

THE HESSLE GARDENERS' SOCIETY.—The usual fortnightly meeting of the above Society was held on Tuesday, January 26th, Mr. Geo. Wilson (Swanland) in the chair, when a paper was read by Mr. Chas. Lawton, gardener to W. H. Harrison-Broadley, Esq., Welton House, Brough, on "Horticultural Exhibits and Exhibition Plants." The essayist referred to his first visit to a flower show in 1861, at which time fruit was shown in many cases quite equal to any now produced, and regretted that the culture of Pines had become almost a thing of the past. Speaking of the present-day exhibitions, he continued, taking them all in all, they are the best exhibitions of horticultural produce the world has ever seen, and no country can equal our own in producing such splendid examples of Nature's boundless wealth, both in fruits, flowers, and vegetables. Active steps are already being taken towards inaugurating a summer show in connection with this Society, which it is hoped will be successful. —F. L. T.

LIVERPOOL HORTICULTURAL ASSOCIATION.—The eighteenth annual meeting of the above Association was held in the Lecture Room of the Free Library on Saturday evening. The Secretary's and Treasurer's reports were read, the latter showing the Society to be in a better position than last year. The election of officers and Committee followed, several new members being added. Mr. G. Blackmore, Sub-Treasurer, and the Secretary, Mr. W. Dickson, were re-elected. A discussion ensued relative to the number of exhibitions to be held this season, it being decided to again hold grand summer and autumn shows. The Society has always endeavoured to have the shows of a high standard, and regrets exceedingly the poor attendance at the spring shows. The Committee earnestly hopes that the public at large will support the forthcoming exhibitions, and endeavour to place the Liverpool exhibitions up to the high position of a few years ago. A hearty vote of thanks to Mr. T. White, the Chairman, concluded the meeting.

READING GARDENERS' ASSOCIATION.—The annual tea of this Association was held in the Abbey Hall (lent by Messrs. Sutton and Sons) on Monday, the 25th ult., when the newly elected President, Mr. C. B. Stevens, presided. The party numbered about 100. After justice had been done to an excellent repast, the President read letters which had been received apologising for the unavoidable absence of several gentlemen. The second part of the meeting was a new departure as far as the Gardeners' Association is concerned. It was thought advisable to try and save the expense of engaging professional talent to carry out the entertainment and to have a smoking concert, the programme to be sustained by the members, and, with one or two exceptions, this was done. The new arrangement proved a great success, and was pronounced to be one of the most enjoyable entertainments ever held by the Association. In an interval in the programme Mr. T. Neve took the opportunity of proposing a hearty vote of thanks to the President. This was seconded by Mr. Dearlove, and carried unanimously. Mr. C. B. Stevens, in reply, thanked the members for the great honour they had done him in electing him their President for the year 1897, and said that although a stranger to most of them he hoped this would not long remain so. He confessed that he knew little of the practical part of gardening, yet he knew that the gardeners' was one of the most difficult of crafts, requiring a great amount of forethought, care, and knowledge, and he considered that these social meetings and their meetings devoted to lectures were most valuable, as they enabled them to know each other better, and to obtain knowledge from one another which would help them in their work and in their Association.

— GARDENING APPOINTMENT.—Mr. J. P. Kendall, hard gardener and bailiff for thirteen years to the late H. L. Holland, Esq., Templeton, Roehampton, S.W., has been appointed in a similar capacity to J. P. Gassiot, Esq., The Culvers, Carshalton, Surrey.

— DEATH OF MR. ALEXANDER CURLE.—We regret to have to announce the death of Mr. Alexander Curle, which took place a short time back at Priorwood, near Melrose Abbey. Mr. Curle took a keen interest in botany, and had an observant eye for all things beautiful in Nature. He had a knowledge of all classes of horticulture, and his garden and grounds were an interesting study.

— WINCHESTER GARDENERS' ASSOCIATION.—On Tuesday the 26th ult. Mr. P. H. Foulkes, B.Sc., M.R.A.S. (of the University Extension College, Reading), gave a lecture on "Insects Injurious to Plant Life, and How to Deal with Them." The lecture was made more interesting by the different subjects treated on being clearly shown by the lantern. The principal subjects were the winter moth, eelworm, and weevils, giving the life history of each, the time when they could be dealt with successfully, and the best methods of doing it. Many useful and practical hints were given, and the lecture was highly appreciated. A vote of thanks was given to Mr. Foulkes for his lecture.

— A TREE DIAMOND MEMORIAL.—The intimation that a northern nobleman proposes to plant some trees on his estate in memoriam of the Queen's sixty years' reign seems to be a singularly happy one. It is a suggestion that might be acted upon in a thousand directions, not only by private landowners, but by many public bodies who have parks or open spaces of considerable area under their control. There are several parks in London, for instance, where sixty enduring trees, such as the Oriental Planes, might be planted, either in one huge group or in several, or in avenue form. In how many large private parks might not a grand group of sixty trees become in time one of the finest objects in the landscape! Those whose parks or land are limited might plant Thorns, Laburnums, or small Conifers, or even shrubs. In other directions fruit growers might plant specially selected sixty trees of Apples, Pears, or other fruits. Wherever so planted and labelled these trees would have enduring interest as a memorial of the Royal event of the century, one so far unique in the history of England. In how many small areas and gardens might not a single memorial tree be planted! Indeed, were this idea acted upon generally it is not too much to assert that over a million of such memorial trees would be planted during the present year. In the majority of cases the planting would have to be done in the autumn, as the month of June for the purpose would not do. That is of little moment so long as planted in the diamond year of 1897. I venture to think this proposition is very sensible, is very practical, and most certainly is eminently fitted to benefit horticulture.—A. D.

— WAKEFIELD PAXTON SOCIETY.—Under the title of "Rambling and Scrambling among the Alps," Mr. J. W. McPherson, B.A., of the Wakefield Grammar School, delivered a highly interesting lecture at the meeting of the Paxton Society held on the 23rd ult., in presence of a good company, over which Mr. W. Tunnicliffe, Denby Dale Road, presided; Mr. J. G. Brown, Outwood, being Vice-Chairman. By the kindness of Mr. Harold Parkin, who lent and cleverly manipulated his lantern, the lecture was profusely illustrated with excellent slides obtained by the lecturer for the occasion. Mr. McPherson eloquently and felicitously described the pictures presented, the earlier part of his lecture and the accompanying illustrations setting forth the beauties of Lucerne, the lovely villages nestling on its shores, the resorts of tourists upon the hills around, and the wonders of Pilatus and the superstitions of the natives in regard thereto, and gave many interesting details of the Righi, in the ascent of which botanists might see a marvellous variety of floral specimens, including the Harebell, which was of large growth and tinged considerable patches of the slopes with blue. At one stage of the lecture Mr. McPherson gave his audience an example of the unmusical call of the mountain horn, so much in use in the Alps by tourists and others. The references to Schiller's *ahode* and Tell's Chapel and monument revived in the minds of the audience the legends learnt in their boyhood, and were also a diversion from the beaten track followed by the ordinary tourist. Having described the ascent of Pilatus by railway, the lecturer passed on to the St. Gothard district, and exhibited many picturesque or otherwise interesting views, embracing the Rhone glacier, Basle, and the Rhine. Concluding, Mr. McPherson said our own north country scenery compared very favourably with the much-vaunted scenery of the Alps. The lecturer and Mr. H. Parkin were cordially thanked for their services.

— SOUTH SHIELDS WEATHER.—Mr. Bernard Cowan writes:—"We are having severe weather here just now. The thermometer has only been 11°, but the north-east wind has been of the bitterest description. I am more than anxious, as we have 17,000 Wallflowers planted out this spring and 8000 Stocks."

— JANUARY WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected), 33.80°. Wet bulb, 33.17°. Mean maximum, 38.01°; mean minimum, 30.66°. Highest, 43.6° on the 1st; lowest, 18.8° on the 26th. Mean of maxima and minima, 34.33°. Mean radiation temperature on the grass, 26.93°; lowest, 14.6° on the 25th and 26th. Rainfall, 2.44 inches. Number of rainy days, twenty-one; greatest amount on one day, 0.36 inch on the 7th and 8th.—W. E. LOVEL, *Observer, York Road, Driffield.*

— WINTERY WEATHER.—A touch of real winter has been experienced over the British Islands during the past week, and the thermometer has in many places registered a lower reading than on any previous occasion since winter set in. Towards the close of last week, and especially on Friday and Saturday, snow fell very generally at many of the English stations, and on Saturday night there was a heavy fall in the metropolis. The snow quickly disappeared from the more crowded parts of London, but it remained unhawed in the suburbs on Tuesday morning. The thermometer in the screen at night has registered 10° or 12° of frost in many parts of Great Britain, while the exposed thermometer, on the grass, has fallen several degrees lower. The type of weather over our islands has become anticyclonic; and if these conditions continue a spell of settled cold weather will be experienced.—("Nature.")

— PRESENTATION TO MR. CYPHER.—In a recent issue we called attention to a supper that had been given by this well-known nurseryman to his employes to commemorate the attainment of his seventieth birthday. It appears that the object of the supper came as a complete surprise to the men, who were consequently unprepared to make any recognition of the interesting event at the time; but as the outcome of subsequent action of the men, who were determined not to let such an event pass unrecognised, Mr. Cypher was on Friday night the recipient of a handsome armchair as a mark of the high esteem in which he is held by the men, and of the cordial relations that have so long subsisted between employer and employed. The presentation was made by Mr. Richard Cull, who expressed the hope that their respected master might long be spared to enjoy the ease and comfort he so richly deserved. Mr. Cypher was much affected by this mark of appreciation.

— ANOIGANTHUS BREVIFLORUS.—This has been known to botanists for over fifty years, but it is only within the last decade that it has been in cultivation. It is a bulbous plant nearly related to the *Cyrtanthus*, and is a native of several portions of Eastern South Africa. Its value lies in its being an easily cultivated plant, which flowers freely when once established, and generally during the winter or spring months. At present, says a contemporary, it is not common, and it would be a gain to horticulture if a large importation of it could be made so as to enable it to be grown in quantity. There is one mass of it which bore four spikes of flower in the Heath house at Kew, which is just sufficient to show what a charming display could be made with fifty or one hundred scapes grouped with Maidenhair Fern or some such plant, for it is itself destitute of foliage at this season. Strong scapes carry from nine to a dozen flowers, which are of a clear bright yellow. The segments of the perianth being 1½ inch to 2 inches long. It requires quite cool treatment, and may be grown in an unheated frame.

— BEGONIA GLOIRE DE LORRAINE.—Gloire de Lorraine, of which there is a notice and illustration on page 48 of the *Journal of Horticulture*, well merits the praise it has received, as it is undoubtedly a valuable acquisition. As seen during the last months of the past year in the Oxford Botanic Garden it was exceedingly pretty; dwarf compact plants 10 to 12 inches in diameter were so profusely bloomed as to present really delightful masses of clear rosy-pink flowers so dense as to almost envelop the neat foliage that emerged from their lower branchlets, as though designedly to garnish the rims of the pots in which the plants were growing. There is a distinctive prettiness in this Begonia that makes it particularly welcome, especially at a season of the year when flowers are none too abundant, and a quality that will doubtless speedily win for it universal favour. The parentage of this triumph of hybridisation is said to be Begonia socotrana and B. Dregei, the former being introduced into this country by Professor J. Balfour, I believe, during his directorate of the Oxford Botanic Garden. Mons. Lemoine may be heartily congratulated on having raised and distributed such a charming hybrid Begonia as that of Gloire de Lorraine.—JOHN E. JEFFERIES.

CALANTHES VEITCHI AND VESTITA.

It is much to be regretted that the above *Calanthes* are not nearly so well grown as they were some few years back, not that it is altogether lack of knowledge of their cultural requirements, but the numerous hybrids and importations so frequently appearing seem to have relegated these beautiful and useful winter-flowering Orchids to a much lower position than they deserve. Yet the fact must not be overlooked that either as cut flowers or for decorative purposes in pots we have few modern Orchids that are so accommodating, the length of stem when cut being of great service, whilst for grouping they can be so arranged as to present the most graceful appearance, the lasting properties of the flower spikes being a great feature in their support. The variety *Veitchi* is certainly the more valuable, and if the late Mr. Dominy did no more than raise this one variety it was sufficient to keep his name perpetuated.

Having had for some years past to keep up a large supply for various purposes I am sending a few notes on their culture, also some spikes from plants which have not been repotted for three years. They are not of the best, yet you will see how bright and useful they are at this dull season.

After the plants have finished blooming they may be kept on the dry side until the new growths are seen to be moving. Many growers let them start in the old compost, and with careful watering, or if they are to be grown in it a second season, it is all well and good, but ours are shaken out of the pots and laid in a box of charcoal and sphagnum, into which they soon begin to make new roots, and when ready for potting they lift much easier and have a portion adhering to the roots, no check being experienced. The cultivator must determine on the size of pots suitable to his requirements; the largest sized pseudo-bulbs may be placed singly in 5-inch pots, 7-inch for three, and 9-inch for six bulbs. The pots must be carefully drained.

The compost we use is composed of two parts fibry loam, one peat, with the remaining part coarse silver sand and dried horse droppings. The latter I use in preference to cow manure, as being sweeter and less liable to get sour. Some rough pieces are placed over the drainage, and fill up level to the rim. A small stake is placed against each pseudo-bulb to keep them in position until they have taken hold of the soil, when they may be filled up to the rim of the pot with the same compost.

After repotting a moist growing temperature of from 65° to 75° will suit them to a nicety, watering most carefully at first, gradually increasing the supply as the summer advances, giving weak guano water about twice a week, and shading from hot sunshine. When the flower spikes can be detected at the base of the pseudo-bulbs less water will be needed, and if when in flower the plants can be arranged in the midst of a bank of Maidenhair Fern and Asparagus the effect is greatly enhanced. If a larger stock is required break the pseudo-bulbs at a joint, and lay them on some sphagnum moss, when growths will be the result in almost every instance.

To sum up, success is only to be obtained by moderate watering after repotting, heat and moisture, with shade from strong sunshine during the summer, weak applications of liquid manure, which helps to consolidate the pseudo-bulbs, and growing from start to finish without a check.—R. P. R.

[Our correspondent has taken an excellent means of proving the correctness of his methods of procedure by forwarding specimens of the flowers, the cultural details of which he treats so well in the preceding paragraphs. The spikes are of good length, the flowers even and closely distributed on them, and what is more advantageous all on one side, thus allowing each to be seen readily. Though the notes above deal with *C. Veitchi* and *C. vestita* only, there are many others of great utility—namely, *C. porphyrea*, *C. rosea*, *C. Limatodes rosea*, *C. Veitchi lactea*, and *C. sanguinaria*, each of which is represented in the engraving (fig. 24)]

ORCHID SALES.

WEEK by week and month by month bring in their train that institution of a comparatively recent growth—the Orchid sale. One may always purchase Orchids at the sale rooms of Messrs. Protheroe & Morris in Cheapside. Not a lot of rubbish, but good plants from sound and reliable sources. On Friday last Messrs. Sander & Co., St. Albans, had sent a large consignment of Orchids

in and out of pots, though, owing to the weather, nothing of startling merit was noticeable. Buyers were not particularly numerous, but the plants were rapidly taken up. On Friday, February 5th, there will be another Orchid sale, the specimens this time coming from Messrs. W. L. Lewis & Co. and J. W. Moore, and comprise numerous lots of *Cypripediums* and *Odontoglossums*.

A GARDEN IN THE ISLE OF WIGHT.

[An Address (amplified) by Rev. H. EWBANK to the members of the Horticultural Association at Newport.]

(Continued from page 71.)

SPEAKING of winter flowers, by which I mean those that blossom in the dead time of the year—long before *Helleborus colchicus* has put in any appearance, and running a race with *H. niger* itself—I know of nothing which more astonishes a beholder for the first time than some *Irises* do. *Iris stylosa* and its very desirable varieties, such as *pavonina* and *speciosa*; *Iris Histrio*, *I. histrioides*, and *I. Danfordiae* charm away the desolation of winter, and, at all events in the Isle of Wight, lighten up the borders in a way which could never have been suspected beforehand.

I was once walking along the road in December with a blossom of *Iris stylosa* in my hand, and I happened to meet Sir W. Hutt. A flower was certain to draw him, and he stopped me and asked me what I had chanced to get hold of. I told him at once, and he then wanted to know where and how it was grown. I explained to him that it came from the open border, and called for no attention at all, whereupon he remarked, "How foolish I am to spend so much money for coals to grow Orchids if you can do a thing of this sort without any expense." *Iris stylosa* is of a most captivating lavender colour, very delicate indeed, and quite certain to please. There is also a white form of it, which should not be overlooked. The great mistake in growing it is that of catering for it too much. It does best in a dry, hungry soil, and will then blossom profusely.

Iris Histrio is a most charming little bulb, and quite as much at home with me as if it were on the slopes of Lebanon. It often comes upright through the snow, and is quite a winter flower. It differs from *Iris reticulata* mostly in point of colour, which, to use Professor Foster's words, is as follows:—"The fall in its central parts is of creamy white dotted over with blotches of a bright blue; these blotches fuse together at the edge and tip of the fall into a uniform ground colour of blue; the blue, however, is not a pure blue, having a slight admixture of red." *Iris Danfordiae* is of a very rich yellow, and therefore noticeable in the dark days of the year; but it is small, low, and "the inner segments or standards of the flower are reduced to mere spikes, hardly visible when it is looked at in the ordinary way." Sandy loam is what these bulbous *Irises* require, and no one should be without them who has a garden at Ryde.

And soon we come to a time when it is difficult to select. There is no season of the year like spring; there are no flowers like those of its opening months. *Flores sunt sidera Terræ*, and the early flowers of the year sparkle like jewels in the ground—so bright and so various they are. The string of names that could be given would utterly weary you. *Muscari*, *Chionodoxas*, *Scillas*, *Fritillarias*, *Crocuses*, *Anemones*, *Narcissi*, *Trilliums*, and a thousand more form a concatenation of beauty which could not be exceeded. The *Anemones* are known to you all, and I will say a word about them, as some choice must be made. The origin of the name is a matter for speculation. Some say that it comes from the Greek word *anemos*, wind, and that the *Anemone* is very much blown about in the gusty month of March, and that the flowers do not expand till then. Certain it is that they are very often found in bleak windy places; but on the other hand the flower seems able to defy any storms to which it may be exposed, and the petals cling tightly to the stalk. Another explanation is that the seeds of the *Anemone* are light as thistledown, and they are tossed hither and thither as soon as they are ripe.

There is a large number of species which come from the South of France, Italy, the Levant, Palestine, and other countries. In Palestine the masses of *Anemone fulgens* are called the Saviour's blood drops, and in some places you can hardly walk at all without stepping on them. The finest show of this sort that I have seen was on the Pic de Sancy in France, where millions of *Anemone sulphurea* and *A. alpina* were nodding together in beautiful and indiscriminate profusion. The *Anemone* has three colours—red, yellow, and blue, and in that respect it is on a footing with *Lilium*; but I do not remember anything else in the same way. *Anemone blanda* is of a rich blue. *A. ranunculoides* is yellow, and *A. fulgens* is red. In Britain we seem to have three species—*A. nemorosa*, *A. pulsatilla*, and *A. ranunculoides*; all these are most delightful in the garden, and so are *A. narcissiflora*, *A. palmata*, *A. apennina*, and *A. sulphurea*. I should be sorry to be without any one of them, and *A. nemorosa Robinsoniana* is one of the most delightful of all spring flowers, or as Mr. Nicholson puts it, "one of the prettiest of the whole genus," which comes to the same thing in other words.

There is a magnificent *Anemone*, which was raised by Mr. Nelson of Aldborough, and which takes its name from its native place. It must be 3 inches or more across, and it runs in my head that even this has been eclipsed by the efforts of Herr Max Leichtlin; if so it would be difficult to imagine anything finer. *Anemone palmata alba* is a plant that loves the Isle of Wight, and my garden in particular, but the odd thing is that *A. palmata* is not of the same mind at all. It does hold on,

and it blossoms occasionally, but the one would soon cover the whole place with its pretty stars if it only had licence to do so, and the other seems to bloom as a favour, and takes no particular interest in it.

With regard to cultivation I do not think I can do better for you than by reading a passage which is full of advice on the part of Mr. Fish, and is of great value. He says that "care should be taken when

or flowers of the next, and, of course, if they are removed or smothered in the middle of their work, these processes are either wholly arrested or imperfectly performed. Hence the great importance of allowing the leaves of Anemones and such-like plants room and time to complete their work properly. They should be planted in September or October. With regard to tuberous-rooted Anemones, it is not a bad plan to take them

FIG 24—CALANTHES.

Anemones are planted in borders that they are not cut off till they ripen and die down of themselves. It is the premature destruction of the leaves of such tuberous-rooted and bulbous plants as Anemones, Snowdrops, &c., that causes them speedily to dwindle and degenerate. The leaves of one season are always engaged in forming the roots, crowns, bulbs,

up and store them in a dry place for a few months. The reason is they often have a late and unseasonable growth. Anemones left in the ground start afresh in wet or growing weather. The strength that might have been expended in making the flower is wasted in the growth of useless leaves in late summer or autumn. It is no uncommon thing to find

Anemones with leaves early in August. The leaves generally reveal the proper time for taking up by turning yellow and flagging. If put in a tray or drawer they may be propagated by division of tuber or they may be by seed. The tuber is a rough, spreading, irregular, rather flat mass, full of gnarly-like protuberances. In most of these there is a growing point, though neither prominent nor conspicuous; the tuber may be cut into as many parts as eyes, and each will form a plant. But propagation by seed is the best and by far the quickest way of increasing Anemones. The seed is difficult to sow by reason of the mass of cotton-like down which adheres to it, being a sort of wings to carry it away. These should be separated by rubbing them in dry sand or soil until it is removed, and there should be a covering of about a quarter of an inch of dry sandy soil."

The genus *Narcissus* now comes in turn before us. The wild Daffodil is a native of England, and it is found abundantly in the Isle of Wight, but not in Scotland or Ireland. Canon Ellacombe tells us that "There are thirty-seven distinct species, besides many varieties and hybrids, and its headquarters are in the South of Europe. A few, however, are found in Northern and Western Asia, one in Teneriffe, and a few in North Africa. None of the family is found wild in America." Nurserymen's catalogues have become perfectly bewildering; so many varieties are so nearly alike. This flower has always been a favourite with the poets. Thus Keats sings:—

"A thing of beauty is a joy for ever;
It's loveliness increases. It will never
Pass into nothingness.
In spite of all
Some shape of beauty moves away the pall
From our dark spirits. Such the sun, the moon,
Trees old and young, sprouting, a shady boon
For simple sheep; and such are Daffodils,
With the green world they live in."

And Herrick cannot be surpassed:—

"Fair Daffodils, we weep to see
You haste away so soon.
As yet the rising sun
Has not attained his noon.
Stay, stay,
Until the hasting day has run
But to the evensong."

The best division of *Narcissus* is into three groups (*Baker*).

I. The Large-crowned or Magni-coronati, which includes those in which the corona equals or excels in length the divisions of the perianth. Here may be placed the *Corbularias* and the *Ajax* section, and such Daffodils as *maximus*, *obvallaris*, *pallidus præcox*, *cernuus*, *minimus*, &c., belong to it.

II. Medio-coronati, of which the crown is half or not more than three-quarters as long as the divisions of the perianth. To this belong *N. incomparabilis*, *Parkinson's Peerless Daffodil*, *N. calathinus*, *N. triandrus*, and others.

III. *N. Parvi-coronati*, of which the crown is less than half as long as the divisions of the perianth. In some it is little more than a raised line; in some it is highly coloured. *N. orientalis* and *N. papyraceus* may be mentioned here, and *N. poeticus* belongs to this group, which is one of the greatest favourites of all.

But my reason for saying a word about *Narcissus* is because I think it is especially a flower which loves this part of the world. Of course there are difficulties about growing some of them well, but it is the exception to the rule when any special trouble occurs. Even the little tender *N. monophyllus* will often do well in the open, and I have blossomed it here several times with nothing more than a little bit of glass over its head to keep off frost and rain. There are some plants which I pre-eminently regard as Isle of Wight plants—by which I mean that while they certainly refuse to do well in many gardens on the mainland, they blossom and increase here in a most free and satisfactory manner. Of such I consider *N. triandrus* to be a very conspicuous example. The petals are reflexed as are those of the *Cyclamen*, and it is without doubt one of the most elegant and graceful of all the flowers by which the month of April is adorned. It seems to have been introduced into this country about 300 years ago, and then it was lost and afterwards recovered. The bulb is very small, rather thin and long; the leaves, generally in threes, are exceptionally tender, and there is everything about it to suggest that it is not very robust.

N. triandrus loves the slight attentions which it receives, and it multiplies in this garden in the most rapid manner. Only last year Messrs. Burbidge and Barr paid me a flying visit in the spring, and Mr. Barr very soon pitched on some of the clumps of *N. triandrus*, with which he seemed to be surprised. Nor is this all which might be said on this head. I fancy that, as a rule, *Narcissi* multiply here in an exceptionally rapid degree, and I am quite certain that they blossom here more satisfactorily than they do in many other places, and they are very highly coloured. Mr. Boyd of Melrose, N.B., told me some years ago that he was very much surprised with the performance of *N. maximus*, both as to freedom and colour, and that he had nothing like it in Scotland.

A very long list might be given of the *Narcissi*, which do well in my hands, but these remarks must be cut short. I would merely add that Mr. Fish has given some good cultural advice to those who have difficulties to contend against. He says, "That the utmost care should be taken of the leaves till they are ripe; in exposed places the winds are apt to twist and bruise *Narcissus* leaves into uselessness. As a rule

they are generally quite free from disease. A species of dry rot may be sometimes found in some bulbs, which is probably the result of excessive drying or keeping the bulbs too long out of the ground. Jaundice is a more difficult matter, and what are called miffy species not seldom go off in this way. A change of soil, the removal of the flower stems as soon as they appear, are the best palliatives that can be named. Blindness is a fault rather than a disease, and is generally caused by overcrowding or starvation." The Rev. G. Engleheart presides over the genus in this country, and with very conspicuous success. Some of his seedlings show a marked improvement upon anything we have had before.

(To be continued.)

IN A GLOUCESTERSHIRE APPLE ORCHARD.

I WAS much interested in reading the article under the above heading by Mr. Alex. Dean which appeared in the *Journal* of the 21st inst., page 54.

It was my privilege to be employed for ten years in the gardens at Lydney Park, and although some seventeen years have elapsed since, I have a vivid recollection of the grand crops of Apples the orchard in question used to produce at that time, having helped year after year to gather and store the fruit which was required for use of the family. Blenheim Orange and King of the Pippins were much in evidence, with other good varieties for culinary use. Cider being the working man's beverage in that part of the country, a good deal of the fruit is used for that purpose and a certain quantity supplied to the men daily, such fruit realising good prices for the purpose named.

It is pleasing to note that Mr. Bathurst, the generous and popular owner of the Lydney Park estate, is animated with a desire to arouse interest amongst his tenants and neighbours in the matter of fruit growing, which no doubt will stimulate them to further energy in the production of British-grown fruit, for which the soil and situation of the locality is admirably adapted; and after Mr. Dean's excellent advice it may be expected that more of the better varieties will be planted in the future than has been in the past.—R. MORSE, *Berkley House Gardens, Frome*.

EXHIBITING DAHLIAS.

I WISH to know to what size show Dahlias are now grown for exhibition, and the size of stands used for twelve and twenty-four blooms respectively. Also I wish to know whether good medium-sized blooms of Cactus, decorative, and single Dahlias weigh more in the estimation of competent judges, other points being equal, than very large blooms, as some remarks in a report of the Dahlia exhibition at the Crystal Palace in 1892 led me to infer that such might be the case.

I shall esteem it a favour if you would inform me the breadth and depth of a good exhibition bloom of a Show Dahlia. I have frequently seen the measurements of *Chrysanthemums* in the *Journal*, but never remember to have seen any of Dahlias. I have no doubt that the Show Dahlia, like the *Chrysanthemum*, is now much larger than those I as a young gardener used to see at home.—H. F., *Uitenhage, Cape Colony*.

[*Size and Qualities*.—The average size for exhibition of a double Dahlia, either "Show" or "Fancy," is 5 to 6 inches across, and 3½ to 4 inches in depth. The "points" of a Show Dahlia are the same now as twenty years ago—fair size, good depth, globular shape, petals well cupped, the centre full and high, but not above the edges of the surrounding petals, and the colours clear and good. Mrs. Gladstone is still the most perfect Show Dahlia.

[*Size of Stands*.—For twelve blooms, 24 inches long, 18 inches wide, holes 6 inches apart from centre to centre; legs 9 inches high at the back, 3 inches at the front. For twenty-four blooms, 48 inches long, and other measurements as before, all painted dark green and varnished. Cactus Dahlias are sometimes shown in this way, too, as single blooms, but most fanciers would think it absurd to do the same with singles.

[*Comparison of Qualities of Different Sections*.—Cactus and single Dahlias are not exhibited together or against doubles in this country, except in groups for effect; but if they were shown against each other in stands the doubles, if perfect blooms, would almost certainly win, a well-grown double Dahlia being one of the most perfect florist flowers that can be produced. Single, Cactus, and Pompon flowers are invariably exhibited in bunches of six or nine flowers, triangular in shape. The qualities of a Cactus Dahlia are medium-sized flowers, produced on long stalks well above the foliage, the petals well twisted, curled, and pointed, the centre full—that is, not showing an "eye," and the colours clear and distinct. Fasilier or Mrs. Wilson Noble are good types.

[*Decorative Varieties* are not recognised now by the National Dahlia Society, but the good qualities consist in freedom of flowering, and displaying the flowers above the foliage for garden decoration.

The points of a good single for exhibition are medium size, petals round and reflexed, but not too much so, and the colours clear and distinct. Mrs. Henshaw (scarlet) is a good example.

The Show Dahlias, unlike the *Chrysanthemum*, have not progressed very much in size for ten years. New colours and form are the greatest improvements. Yellow Globe, John Hickling, Arthur Ocock, Duchess of York, Virginale, Chieftain, Mabel Stanton, Shottesham Hero, and Penelope are amongst the most notable examples of the introductions of the last few years that combine size and the other good qualities. The chief prizes rarely go to the largest blooms, as these are not unfrequently coarse, and coarseness is a defect.]

A TOUR ABROAD BY A HAPPY TRIO.

(Continued from page 31.)

It is certainly worthy of remark and a conspicuous tribute to the widespread influence of the N.C.S. when I say that every exhibit of cut blooms at the Ghent Show was, with one small exception, staged by members, either English or foreign, of the National Chrysanthemum Society of London. The business of judging occupied the best part of the day, and then the jury adjourned to a banquet. The following day was Sunday, and the show was beautifully arranged. On entering we were supplied with a neatly printed catalogue of the show of thirty odd pages, in which were supplied not only the names of the exhibitors and the varieties they had staged, but a list of the prizes, the names of the members of the jury, and other matter likely to be of interest to the visitors. The visitors were numerous, and evidently of good social standing. We spent several hours taking notes and observing in detail some of the more striking variations between a Belgian and an English Chrysanthemum show. Then we remembered an invitation to dine with Mr. Ed. Pynaert. Mr. Ed. Pynaert's nursery lies at some distance off in the Rue de Bruxelles, and, as he reminded us, he was something like Robinson Crusoe, for it is almost an island, being bordered by canals on almost every side. We took a stroll through the greenhouses; but our host is not a specialist in Chrysanthemums, and his stock consists principally of Azaleas, Araucarias, Palms, Ferns, Orchids, and Rhododendrons. Here we had a splendid example of Belgian hospitality. For three hours we were at table, provided with the best of everything, and both Mr. and Madame Pynaert did their utmost to make our visit enjoyable.

We inquired whether there were any establishments, either private or public, in the vicinity of Ghent where Chrysanthemums could be seen, and which were worthy of a visit, but discovered that the best plants were at the show, and so we decided in our anxiety to reach Paris to move on to Brussels early next morning. Mr. Anatole Cordonnier, the well-known Chrysanthemum specialist of Bailleur, just over the frontier in France, was desirous that we should pay his establishment a visit, and came over to Ghent to meet us and make the request in person, but we found it impossible to accept his pressing invitation.

On Monday morning, the 16th of November, we started for Brussels, and knowing the N.C.S. had a foreign member living not far away, a Mr. de Wolf, we decided to give him a call and see his collection. We took a queer-looking conveyance called a steam tramway to Ixelles, and were landed in what appeared to be the heart of a forest of Beech trees, then after a journey by tram and road found ourselves in a curious little provincial town with narrow streets and queer-looking cottages. We found Mr. de Wolf's house after several inquiries, and as he was not at home his gardener obligingly allowed us to go through the greenhouses and view the flowers. There were in all four curvilinear houses full of Chrysanthemums. The total number of plants amounted to about 2000. The best of them were arranged in four rows in a large structure measuring about 100 feet in length by 35 feet wide. They were well-grown dwarf plants, such as might be seen at the house of an English suburban enthusiast, most of the leading varieties being represented. We were pleased with what we saw, for it was the only opportunity as it happened that we had of visiting a private collection while abroad, and thanking the old gardener, who seemed to take a pride in his productions, we returned to Brussels, dined, and caught the six o'clock express to Paris. —C. HARMAN PAYNE.

(To be continued.)

INCURVED CHRYSANTHEMUMS.

THE General Committee of the N.C.S. has bowed to what it has considered the inevitable, and has drafted into the ranks of the "incurved" section a miscellaneous assortment of varieties, many of which have hitherto been classed, in the trade catalogues and even in the catalogue of the N.C.S. itself, as "incurved Japs," or even pure "Japanese."

In face of the general "bolt" of both exhibitors and judges from the old condition of affairs, when a "Queen" or "Empress" was the standard of the true "incurved," it was obvious that the N.C.S., powerless to resist the revolt, would probably be forced to do something; but whether the "something" which the Committee has done will not, in the long run, be found to have provided a remedy far worse than the disease is a question to which it will require the lapse of a season or two to supply the conclusive answer. It seems to me that the exhibitor, having asked for a draught of water, has been treated to a deluge.

With the admission of these twenty-two new so-called "incurved"—the pioneers obviously of an army soon to come—we may take it that the knell of the old Chinese incurved has been rung. It will be interesting indeed to compare the "best eighteen incurved" of 1898 with those of a couple of years ago.

It was perhaps inevitable, in view of the strong pressure which had arisen, to somewhat loosen the stringency of the old standard of an "incurved" so as to permit of the introduction, after a full knowledge

of the new candidate had been acquired, of certain of the new varieties which seemed almost to attain to the old standard; but surely, when we analyse the crowd just admitted, one cannot resist the conclusion that the matter has been altogether overdone.

But the chief danger lies in the future. The only principle which is to guide future action seems to be that stated in the resolution passed, "That the position of any variety shall be determined by the majority of those voting." Naturally the majority must prevail where there is a difference of opinion, but where do we find the standard which is to influence and form that opinion, and so provide that it shall be a constant quantity, and not vary with the individual notions of the members of the Committee in the future?

I am aware that the action of the Committee in making these additions to the incurved class is supposed to have been upon the basis of the Society's definition of an incurved, but such a suggestion can scarcely be accepted; certainly not if we are to believe for a moment in the consistency of those responsible for the definition in question. The definition stands in the centenary edition and also in the Jubilee edition of the Society's catalogue, and with this definition before them Messrs. W. H. Lees, C. H. Payne, and H. J. Jones, as members of the Revision Committee, classed Duchess of Fife and Mrs. Airdree as Japs, and Egyptian as an incurved Jap.

The same gentlemen, with others, on the late Special Committee proceed to group these varieties with the "incurved," as "being varieties which may be regarded as incurved, according to the standard of characteristics set forth on page 20 of the Jubilee edition of the Society's catalogue." It is all very well to take the bull by the horns in this fashion, but which do these gentlemen mean, and on which occasion were they right in their interpretation of the definition? If these varieties had the "characteristics" of the true incurved when the catalogue was revised for the Jubilee edition, why did they class them as Japanese?

Again, Miss L. D. Black, classed by Mr. Wells in his catalogue as a "Jap," which, "on second crowns or terminals, is almost as pure an incurved as it is possible to get," and which was, so late as the 25th of November last, declared by a large majority of the Floral Committee of the N.C.S. not to be an "incurved," is, on the 25th of January inst., unanimously declared by the Society's Committee to be one. And other cases might be cited. Of course, there is the convenient retreat covered by the plea that the true character of the varieties had only been discovered after the earlier classification; but this only adds emphasis to an old complaint, and is an admission that classification takes place before the varieties have been fairly tested. And how about such discoveries of latent character between the 25th of November last and the 25th of January inst.?

The cases which I have cited show that we have drifted away, for better or for worse, from the old standard, and have now no real standard applicable to the "reformed incurved" at all. What can more forcibly demonstrate the confusion which prevails at the present time than the following?

The Special Committee declares Sir Trevor Lawrence, which Mr. Jones in his catalogue calls an "incurved," to be a "Japanese incurved," and so classes it; and then defers the classification (votes being equal) of Harold Wells, which, in fact, is a primrose sport from Sir Trevor Lawrence itself. Truly a curious result of the "one man one vote system."

"What is done cannot be undone," but it behoves the Society to lose no time in getting back on to safe and definite lines by carefully constructing a definition which shall be a reality, having regard to the character of the varieties now admitted as "incurved."

The floodgates have been opened, and the stream has commenced to run with a vengeance. Unless it be confined within definite and recognisable limits it may soon get altogether beyond control.—TOKIO.

THE VICTORIAN MEDAL.

AN admirable suggestion of yours, Mr. Editor, so far as relates to the interests of the Gardeners' Benevolent Institution; but it has the demerit of suggesting that the proposed medal of honour may thus be purchasable, a conclusion from which the Council of the R.H.S. will doubtless revolt. I have no objection to give a guinea to the Benevolent Fund, but not to secure some medal equivalent. If the Committee of the Benevolent Fund had proposed to give to every subscriber to their Victorian Fund of 1 guinea some sort of medal specially struck for the purpose, and commemorative of the year and the event, then might a capital stroke of business have been done, and in such a way as to provoke no hostile comment.

A medal for honour, or merit, or service, or whatever object proposed to be given, must not in any way be associated with cash payments. However, it does seem to me that in the ranks of horticulture it would be nearly as easy to name 1000 good men deserving the honour as to name twenty. There are numbers doing good and honest work in their respective spheres, though often unnoticed, who are in their ways as meritorious as are others who have greater opportunities. That much you, Mr. Editor, know as well as I do. With respect to medals for special work, what I meant was that whilst these Victorian medals would probably be given for general service to horticulture, special medals, such as those of the Fruiterers' Company, could only be secured by special work or service.—A FELLOW OF THE R.H.S.

[A good "Fellow," too, and we are glad by having nearly drawn a guinea from him for the Gardeners' Benevolent—it only needs to be

sent to us to be forwarded. We quite anticipated the objection to our proposal, which is valid, but if it earned a guinea to the charity few will complain. It would seem that our friend's supplementary proposal does not differ very materially. He had better send his guinea, lest, peradventure, he should become a medallist and then object to pay—"on principle."]

LLANGEDWYN.

"FAR from the madding crowd" is literally true of Llangedwyn, one of the Welsh seats of that illustrious family—the Wynns of Wynnstay. It is best approached by road from Oswestry, a distance of about twelve miles, and given summer weather it is a most enjoyable drive; not so, however, in dry windy weather, for the limestone dust from the roads and the lime itself from the numerous lime kilns *en route* combine to prevent any undue gazing at the scenery.

If we digress slightly through a valley running nearly parallel with the Vale of Llangedwyn we are repaid by a beautiful panorama of mountain scenery, and whilst almost lost in admiration we come upon a site of an old habitation of which hardly anything besides a mound and a moat remain, denoting the once stronghold of the wise and brave leader of the "Cymry" in the troublous times of Henry the Fourth, who himself is supposed to have set fire to the above stronghold during the temporary absence of the chieftain, "Owain Glyndwr." Leaving "Lycharth" and its remains we cross the hill into the Vale of Llangedwyn, and quickly find ourselves within the beautifully kept grounds of the mansion.

The Dowager Lady Williams-Wynn, an enthusiast in gardening, has done great things during her residence in transforming the strictly formal garden into one of the most interesting to be found in the country, and Her Ladyship's good taste and enthusiasm are creditably reflected in the head gardener, Mr. Squibbs, who served formerly in the capacity of foreman at Wynnstay.

The first objects of admiration on approaching the grand entrance are the stately Limes, which form an avenue leading to the mansion, its only drawback being that it is a wee bit short. The church on the opposite side of the main road faces the entrance, and forms a pretty picture as seen from the house through the avenue. To the left of the avenue is an extensive kitchen garden, divided diagonally by grass paths, and devoted to lots of choice flowers, besides the culinary necessities. Roses in abundance, gems of the herbaceous families, of which Her Ladyship is particularly fond, Dahlias, Gladioli, and most other kinds. We noticed a fine plant of *Romneya Coulteri*, the picture of well-doing, which flowers abundantly; and the cream of florists' flowers might be seen here in all kinds of happy nooks.

A peep into the glass department within the walls in the summer reveals a state of high-class gardening, and if anything must be specially mentioned it is the splendid collection of tuberous Begonias, which include the most up-to-date doubles and singles. We pass with the bare mention Vines and Peaches with a general verdict of excellent, and come to a cool lean-to house devoted to Roses—Teas and Hybrid Teas—which are a remarkable success, and, as can readily be imagined, of considerable value during early spring. Indeed, the Roses in and outdoors seem to thrive admirably, and whilst still under the spell of those in the house referred to we emerge suddenly upon some veterans whose charms are resistless. One is a *Rêve d'Or*, occupying and furnishing completely a high wall and trellis, about 30 feet run, in the happiest condition, and an equally good companion plant of *Bouquet d'Or*. How many a gardener would delight in having such a pair of pictures!

Within the semicircle where these Roses are, specimen Hollies, beds of *Tritomas*, splendid masses, which are heavily mulched each autumn, with grand results; autumn-flowering Heaths, used as borderings; and a fine plant of *Choysia ternata* were the chief items, the latter indicating either a greater hardiness than it is usually credited with—or a better climate than we would expect at so high an elevation. Near us is a fine specimen of Tulip Tree, and as we proceed we come in sight of some grand old Box hedges 9 or 10 feet thick and as much high.

We are now on the lowest of a series of terraces which rise on the naturally sloping ground flanking the mansion to the right, or the opposite side from the kitchen gardens. Each terrace has its retaining wall, and these are variously furnished with Apples and Pears, Apricots (a fine lot of trees), Peaches, and Plums. The higher terraces, which comprise the flower gardens, have their supporting buttresses clothed with Clematis in all leading sorts and colours—a very pleasing effect between the fruit trees. The borders to the front of these walls are well furnished with herbaceous plants, a rich and varied collection; plentiful use is made of choice annuals also during summer, but at no time are these borders dull and uninteresting; and whilst it occurs to us, the beds of Pæonies which are in season such a feature here, we had already passed in the other portion of the garden.

A platform at the end of one of the terraces enables us to have a splendid view of the flower garden, to the back of which a closely clipped Laurel hedge merges in the woodland; a splendid *Cedrus atlantica* stretches its limbs over a large space of lawn, in which formal beds of the ordinary summer bedding plants with serpentine and scroll beds are well and not too thickly arranged. The dwelling itself is snugly clothed with a variety of creepers, so that hardly room for another is left; standard-trained Heliotropes form a sentinel-like row next the front of the house, standing in beds, the dwarfer occupants of which for the most part are tuberous Begonias.

We are sorely tempted to enumerate and dwell on the gems in the herbaceous borders, but they are too numerous, and our scribble would bear so much semblance to a trade catalogue; so we forego this pleasure, and hasten to prepare for our twelve-miles drive.—BRADWEN.

DOUBLE YELLOW DAFFODILS.

DAFFODILS again! It is nearly two years since I wrote about this old Daffodil for flowering from Christmas onwards. With experience, taking one season with another, there is no difficulty in doing this, but to accomplish it no time must be lost from the lifting of the bulbs, boxing them, and pushing them forward in their various stages as rapidly as possible. This year we did not have them in flower at Christmas. We took things fairly easy, because we had no need for them at that festive season, and we had such an abundance of Chrysanthemums. We were, however, able to cut the old double Daffodil during the early days of January, and had ample with which to furnish a dinner-table on the evening of the 10th ult. for twenty-four people. How we manage these Daffodils may be useful to others. I know it will from inquiries received, and therefore I will give every detail of culture necessary.

I obtain my bulbs from my father in the fens of Lincolnshire, where the old double "Daff" is at home and many other kinds beside. He lifts my bulbs when the foliage is dying away, and the leaves have practically done their work, consequently a fortnight is saved. The bulbs are spread out in the sun to dry, sorted, and dispatched. I have them sent with the old roots attached, not pulled off. Perhaps when taken off the bulbs look better, but it is only a matter of appearance. By this method I have the bulbs before the trade receive theirs, and after they do receive them some delay is occasioned by the further process of cleaning and sorting.

Directly the bulbs come to hand they are turned out for fear they should become heated, and are at once packed closely together in boxes. The boxes are about 2 feet long, 1 foot wide, and 3 inches deep. They can be any size. I like them a trifle deeper. A little leaf mould or old Mushroom bed refuse is placed at the base, then a layer, generally of old potting soil. Any kind of soil will do provided it is fairly light and rich. The boxes should be full of soil well worked amongst the bulbs and made firm. No water is given, the soil must be intermediate for moisture at the time of boxing.

After boxing they are placed in a fairly cool place outside and covered with fine ashes, a good depth, say 9 inches, so that we are certain the soil in the boxes will not become dry. They remain in this position for about six weeks, or until the boxes are a mass of roots, and the tops have grown about 1 inch. The next move is into a cold frame, the lights closed, and a mat thrown over, admitting light gradually. They soon turn a semi-green. Let me here say no water is given in this stage, not even syringing; as a rule with the shade and the frame closed sufficient moisture is condensed upon the plants for their requirements if they stand upon a base of ashes. Cultivators are too fond of pouring water into the pots and boxes of bulbs in their early stages.

From this stage, that is, from the time they are semi-green, two or more boxes according to requirements are removed from the cold frame. Where they are removed to is somewhat difficult to describe, but it is a position we have found from experience to suit them exactly. The house in which they are placed is a cool Carnation house, span-roofed, and in the centre the main pipes enter by means of a brick chamber, the end into the house being open. A little heat always comes up in this position, what the temperature is I cannot say. The boxes are stood on the floor opposite this open chamber, and one side of the boxes soon displays signs of movement, when they are turned round until activity is visible over the box. This is rather a drying position, but the boxes are not watered, only syringed twice daily.

Some may think we grow Daffodils without water, and thus attribute our success; such is not the case. Our object is to keep the soil in which they are boxed in an intermediate state for moisture as long as possible, and after the flower buds are visible we water freely, but resort to no system of feeding by means of liquid manure. If the soil displays a tendency to be dry, we give a good soaking and then follow the syringing process again. From the floor of the Carnation house we remove the boxes to any house where a genial temperature of about 55° is maintained, where they remain until the flower buds are visible all over the boxes. From this they are placed in a temperature of 65° to 70° at night. We do not believe in an excessive high night temperature, and really prefer 60° to 65° to the higher one. If wanted by a given date, a high temperature may be maintained with safety without the fear of many going blind—a few odd ones will certainly do so. When open we remove them to cool quarters again, if only for a day or two, before cutting, which gives strength and solidity to the stems and foliage.

These are the principles which we follow, and a very similar method is adopted for early Tulips.—WM. BARDNEY.

ENDIVE.—The Endive is usually esteemed as a salad plant, but some people consider it too bitter for that purpose, and Professor Waugh states in a late bulletin that it makes most excellent greens when cooked. The variety known as the Ever White Curled does not run quickly to seed, and when blanched like Celery or Cos Lettuce by tying up the leaves or drawing the soil up about the plant it makes an attractive salad plant. For eating cooked, however, it is best to take the plants when very young before they have time to make heads and when they are in their tenderest stage. The seed can be sown early in cold frames or in the open ground like Lettuce, and of course plants can be grown in from forty to fifty days at any time during the summer, but in the very hottest weather they are not of the best quality. Autumn-grown plants can be taken up with some earth adhering to the roots and stored in a dry cellar or in a cold frame for winter use.—("Garden and Forest.")

LILIUM CANADENSE.

THIS usually grows about 2 feet high, producing slender stems, clothed, lanceolate leaves arranged in whorls, and terminated by a few pendent flowers; the perianth is bell-shaped, yellow, spotted inside, especially below the segments, slightly recurved (see engraving). It is a very distinct and, to my mind, pretty species, and can easily be distinguished by the bulbs, which are often supported on almost naked runners. It was one of the first introduced Lilies from America, having been figured by Parkinson (Parad. 32, t. 2), where also a good description is given. It is very variable in character, mainly in colour, as distributed over the continent of North America, passing from yellow to deep orange red.—C.

THE YOUNG GARDENERS' DOMAIN.

R.H.S. EXAMINATION.

I MADE a promise recently which the Editor has allowed me to keep, and below will be found my friendly lecture.

The R.H.S. examination will be held this year on the 6th of April, and all candidates wishing to sit must send in their names to the "Secretary, 117, Victoria Street, London," not later than the first week in February. If any young gardener would like to sit, and there is no centre near, he should ask the clergyman or schoolmaster in his district to conduct an examination on his behalf. On the night of the examination a paper of questions is given to each candidate. Look through the paper carefully, and read the rules, if there be any, following them out explicitly. Then read through the questions, and mark those you can answer best, selecting and answering the easier questions first, leaving the more difficult until last.

Before beginning to answer the questions, read each one through carefully and try to understand its real meaning; then give your answer clearly, in the fewest words possible. Read through your answers, and see that you have made no mistake, or left anything unanswered. It is always best to divide the question into parts where several items are asked; take each part separately and answer it, putting *a*, *b*, &c. (in brackets), before the separate answers, similarly to the way I have in my answers.

Make use of every minute of the two and a half hours allowed—which I think is half an hour too short—and only reply to what you are asked, for I know from experience what a tendency there is to drag in something which has nothing to do with the question. My advice to those who intend to try to gain the medal, or a first-class certificate, is, every night try and read something about the work you have that day been engaged in doing, and when finished, ask yourself a question and write out an answer to it. Read how others do the same work in which you are engaged, and try to think which method is best. Buy Mr. J. Wright's "Primer of Horticulture" (1s.), Mr. R. P. Wright's "Agriculture" (1s. 6d.), and Mr. J. Oliver's "Elementary Botany" (2s. 6d.), and from these you will be able to get sufficient information of a scientific and practical nature to answer any questions you may be asked at the R.H.S. exam.

And now, young gardeners, take my advice, go in for the exam and win, and if you get the medal before I do, no one will be more pleased at your success than—A STUDENT.

POTTING.

FIRST in this important branch of plant cultivation we must have clean pots, and a stock should always be ready when wanted. If dirty pots be used much harm will be done to the plants by their roots clinging to the sides when the plants are turned out for repotting; and besides, dirty pots are unsightly and discreditable.

Next comes the draining of the pots. This must be carefully done, or stagnation at the roots will ensue, ending in the ruin of the plants. The proper way to drain a pot is to place the outer part of a piece of potsherd over the hole, cover this with a layer broken smaller, finishing with the smallest at the top. As to the depth of drainage required, judgment must be exercised, according to the nature of the plant and the size of the pot. For thumbs two or three pieces would be ample, whereas for a 5-inch pot not less than an inch should be given. A very good guide is, for every 4 inches in depth to allow 1 inch of drainage. Protect with a layer of sphagnum moss or turf, to prevent any of the soil being washed down and choking the drainage.

Soil used in potting should neither be too wet nor too dry; the former will probably become sour, while the latter will not take the water properly. The soil should be rough and open—never sifted, except for cuttings. The chief materials used in potting are fibry loam, peat, leaf mould, sand, horse, cow, and artificial manures. The loam and peat should be broken in pieces with the hand, in different sizes, from a horse bean to that of a hen's egg, according to the size of the plant.

The plants to be operated upon should be watered at least a day before potting, so as to properly moisten the ball. The plant after being potted will not then need water for some time, and the roots will heal that may have been damaged in shifting from one pot to the other. In potting never fill the pots full of soil, but leave space for sufficient water to pass to the drainage. For plants in 6-inch pots three-quarters of an inch suffices, up to about 2 inches for the largest pots.

In using the new soil, it should be used of the same firmness all

round as the older central ball. For hardwooded plants the soil requires to be rammed solid, to prevent the water making its way down the sides of the pots, leaving the centre dry. For stove plants the soil should always be warmed through, so as not to give the roots a chill, which is harmful.

After potting the plants should be kept rather closer, until root action has commenced, shading from the hot rays of the sun and syringing them occasionally, again bringing them gradually to full light and air.—J. W.

POTTING CATTLEYS.

FIRST, the pots must be clean and of various sizes, while if new they should be soaked before using them. The crocks should also be clean, and as large as they can be used. The soil must be good fibrous peat, broken to about the size of hen's eggs; if it is rubbed on the hands two or three times whilst breaking most of the small particles will be removed. When much has to be prepared a coarse sieve may be used for the purpose. Potting sticks made of hard wood are necessary. One should be about 14 inches in length for pressing down the crocks, the

FIG. 25.—LILIUM CANADENSE.

other 8 inches for the soil; both should be somewhat pointed, and if rubbed on a smooth piece of iron the hard smooth surface imparted will work freely in the soil.

Imported plants must have the roots loosened, leaving enough to help to fix the plant when potting. Sponge the plants with soapy water, using a rather stiff brush for the pseudo-bulbs, taking great care not to injure the eyes or buds at the base. Six-inch pots and larger may be half filled with crocks, using straight ones, and placing them upright, working more in when the plant is in position until the pot is nearly three parts filled. With smaller pots it is best to hold the plant in position with one hand, working the crocks amongst the roots with the other. Keep the back bulbs against the side of the pot, and if there is room for them to make a season or two's growth in the pot it will be large enough. When there are several leads some must be placed towards the centre as well as the sides, thus making good round plants; if this is neglected there will be nothing but old bulbs in the centre, which make the plants unsightly.

Some growers fix their plants with crocks, placing one end against the rhizome and the other against the pot, letting them stand a little above the soil and keeping clear of the eyes. This is the method I follow, as it prevents the soil going together and getting sour. A stake ought to be placed in the centre of the pot for securing the tallest pseudo-bulb, and keeping the plant firm. If the crocks are straight and placed in the pot upright, the stake will drive down straight; if not, it will loosen the crocks and disturb the plant, and a slanting plant looks slovenly.

Begin potting at the front of the plant, which should be a little

above the rim of the pot, working the peat in firmly, keeping the rhizomes clear; a few heads of moss may also be worked in as the potting proceeds, but not too thickly, as it keeps too wet for a *Cattleya*. When finished the stick should be run around the rim of the pot, making a small groove so that the water will soak through the peat. Finish staking and tying the plant into shape, having the stakes the same height as the pseudo-bulbs.—SECOND OF THREE.

(To be continued.)

GROWING AND FORCING LILY OF THE VALLEY.

No flowers are more esteemed during the dreary months of winter than the fragrant Lilies. They are equally welcome in sprays, wreaths, bouquets, or glasses for house decoration associated with their own charming foliage. When retarded crowns are available for autumn and early winter work, and specially prepared English and Dutch crowns can be procured for early forcing, there is no difficulty in keeping up a supply if good bottom heat is provided.

I wish now to draw attention to a system which combines the minimum of labour and expense with very satisfactory results. To begin with, one must have a good plantation of well-grown crowns established for three or four years. Lilies delight in rich soil and a northern aspect. The crowns should be planted early in spring, 2 or 3 inches apart, in rows a foot asunder. The after treatment consists in keeping the surface free from weeds, affording an annual top-dressing of leaf soil or well-decayed manure, and seeing that the plants do not lack water in the growing season, weak liquid manure being beneficial. At the end of three years, if grown successfully, the ground will be a mass of crowns, and then forcing may begin.

Pieces to fit exactly into ordinary seed boxes should be cut in the early winter, and the boxes when filled stood where they will be exposed to the frosts till required for forcing. When taken in they may be stood on the hot-water pipes under a stage, covered thickly with moss and given abundance of water. In a week or two they will have started growing, and when the flower spikes are visible the boxes must be assigned a light position in a warm house.

By this treatment we have had an uninterrupted supply of fragrant Lilies since the middle of December, and the foliage developed with the spikes. I may mention that in this district (South Lincolnshire) great tracts of woodland are carpeted with Lilies which flower profusely.—O. C.

CONSERVATORY MANAGEMENT.

THIS is a very important and at the same time a very pleasant portion of a gardener's duty. It is a subject about which comparatively little is written, and I am afraid the manner in which some conservatories are managed, judging from the appearance of their interior, admits of very little being said. It makes very little difference in giving a general description of management whether the conservatory is attached to the mansion or only a house set apart for the display of collections of ornamental plants.

In the selection of climbers judgment should be exercised. There is a large variety from which to choose. *Cobaea scandens*, *Tecoma Van Volxemi*, *Clianthus puniceus*, *Lapagerias rosea* and *alba* are all well adapted to certain positions, thriving well and retaining their foliage all the year round. In the case of those climbers which are victims to thrips, green fly, and red spider, such as *Lapagerias* and *Clianthus*, it is a good plan to hang to the rafters with a lightly constructed wirework frame, which should be fastened in such a manner that it could be easily detached. The climbers should then be tied on to the framework. If this is done the task of keeping them clean will be made much easier, particularly where the conservatory adjoins the residence, when fumigating is out of the question. All that it is necessary to do is to take down the wirework frame with the climbers attached, lay it on the floor, and syringe with some insecticide. This operation does not take up much time, and it can be done much more efficiently with the plant on the ground than if it were tied to the fixtures in the roof. Before replacing it wash the rafters with a weak solution of soft soap and water to kill any insects which may be lodging in the crevices. Not only will this method be found convenient in the work of cleaning the plants, but it is equally so when the house has to be painted. Instead of being possibly one or two days in removing climbers, as is often the case, they can be taken down in almost as many minutes and without much injury to the shoots.

In many conservatories there are pillars or supports of different kinds for the roof. It is necessary that these should be covered, and suitable plants must be selected. *Acacia dealbata* is perhaps one of the best plants for this work, beautiful foliage rendering it very attractive even when not in bloom. *Asparagus plumosus* is also very useful and elegant. Plants of *Maréchal Niel* Rose are attractive in association with the *Asparagus*. These Roses should be grown in pots so that they can be easily taken out and cleaned in case of attacks of mildew or green fly. When they have finished blooming they may be taken down altogether, leaving the *Asparagus* alone to cover the pillar. There are many other plants suitable for pillar work which may be used with equally pleasing effect.

Suspended baskets add very much to the beauty of a conservatory. Ivy-leaved Geraniums (*Pelargoniums*) are excellent plants for basket culture, flowering freely, and are highly attractive. The Stag's Horn Fern (*Platycerium alcicorne*), planted in a compost of peat and sphagnum, is also very useful. This Fern will completely cover the baskets and is very effective. Another thing in its favour is that it does not require so much attention as most other plants.

In the selection of the plants which I have mentioned I have not

included any of a deciduous nature excepting the Rose. There are many of this (deciduous) class which are very pretty, but I do not favour them for conservatory decoration, preferring those which are evergreen, so that the roof is always furnished with foliage if not with flowers.—P. W.

(To be continued.)

DRACÆNAS.

ONE of our most useful foliage plants for room decoration, I think, is the *Dracæna*. Its graceful habit, combined with the richly coloured foliage, rendering it attractive in whatever style of decoration it is employed. Especially are well-grown plants adapted for single vase work in 48-size pots. To obtain good plants for autumn and winter work they should be rooted early. The stems and roots of old plants which have grown tall may be cut into lengths of from 1 inch to 1½ inch and placed in well-drained pans of light sandy soil, then plunged in bottom heat of 75° to 80°. In the case of root cuttings I would advise keeping them separate. Give a thorough watering with warm water, but withhold the water from the stem cuttings for a week or so, for by so doing they are not so likely to decay. The tops from the old plants may be readily rooted by placing them in small pots (in the compost advised) and plunged in a close hand-light in brisk bottom heat, shading from strong sun.

As soon as the young plants in the cutting pans are large enough to handle place them singly in 60-size pots, and keep them growing in brisk moist heat. As soon as these pots become filled with roots the plants should receive another shift, taking care, however, not to overpot. A suitable compost is two parts good fibry loam, two parts peat, with enough sand to keep the whole open, to which add a sprinkling of horn shavings or bonemeal. *Dracænas* are subject to the ravages of red spider and thrips, and plants are very soon disfigured if the damping is at all neglected. When the days are bright the plants should be shaded from the sun or the tender leaves will scald. A temperature of 70° to 80° will suit them best.—E. H., Osberton.

GLOXINIAS.

GLOXINIAS are very easy to grow, and should be in every collection of plants. They make a charming display when the different colours are blended together. The flowers being very delicate should be handled carefully. Dotted about in a fernery or a subtropical house shows the plants to perfection. They can be raised either from seeds or from leaves. Seed should be sown as soon as gathered, or in the spring, in shallow pans, using a light compost, watering it previously with a fine-rosed can, covered with a sheet of glass, and shade till germination is apparent. Great care must be taken at this stage not to let the plants get drawn or the soil dry, or the seedlings will perish. When large enough to move prick them 2 or 3 inches apart. When nearly touching each other place them singly in large 60-size pots, using one-third each of loam, peat, and silver sand, and a little powdered charcoal.

Stand them in a frame or pit with a good bottom heat, keeping close and shaded for a few days till they start into growth, when a little air may be given, but avoid sharp currents. Shade on all occasions during bright weather, and close early in the afternoon with plenty of moisture. *Gloxinias* should not be syringed at any time. In a few weeks they will be ready for 48's, using the same mixture as before, adding a little leaf soil.

On all occasions use clean pots with plenty of drainage. Some growers prefer to pot firmly, but my experience has been the reverse. When the plants have commenced to root into the new soil give a little liquid manure once or twice a week till further established, when it may be given every watering. A great point in growing *Gloxinias* is to feed them well, also damp the walls and pathways with the liquid. They will revel in this atmosphere, and give large clusters of blooms with handsome foliage. The night temperature when growing should be 60°, with a rise of 10° in the daytime; when in flower 55° to 60°.—DUNELM.

VINE CULTURE.

(Continued from page 80.)

WHEN the Vines are in flower give the canes a gentle shake two or three times in the middle of the day, which is all free-setting varieties like Black Hamburg, Black Prince, Gros Colman, Gros Maroc, Appley Towers, Buckland Sweetwater, and Foster's Seedling require. Muscats, white and black, should be gone over with a camel-hair brush, or a rabbit's tail will do quite as well, first brushing over a bunch or two of Black Hamburg if in flower, as it has always plenty of pollen; Appley Towers will do as well, and is in flower after Black Hamburg in the same house.

The most difficult varieties to set well are Black Morocco, Canon Hall Muscat, Alnwick Seedling, and a variety of Alicante of which there is one cane here. Have two rabbits' tails, one well dusted with pollen off some free-setting variety; with the other gently take off the little globules of water at the point of the pistil, then with the first tail or brush apply the pollen. Without doing this most of the berries will be stoneless. When the berries are stoning the house may be kept cooler till the berries commence swelling again, when the thermometer may run up to 90° after closing in the evening without doing any harm.

When the Grapes commence colouring more air will be required and ventilation continued much longer in the evenings; in fact, a little all night will do good if the nights are mild. With regard to thinning the bunches and the distance between each berry we must be guided by the variety; Muscat of Alexandria and Gros Guillaume, when the shoulders

are well strung up, require little thinning. Small-berried sorts, such as all the Frontignans and Black Prince, may be left fairly close; Alicante, Black Hamburg, Buckland Sweetwater, Golden Queen, Mrs. Pearson, and Trebbiano require more room; while Gros Colman, Appley Towers, Madresfield Court, Gros Maroc, and Cooper's Black (the last two are quite distinct here, Maroc being larger in the berry and never carrying the bloom of Cooper's Black, both growing in the same house), which are from 4 inches to 5 inches in circumference, must be severely thinned; also Canon Hall Muscat, which has berries as large as Orleans Plums.

To the question, Why do so many fail to grow good Grapes?—by good, I mean Grapes fit to win prizes at our leading shows—I answer want of attention in ventilation, watering, and not keeping the growths pinched back. Never let the thermometer rise much in the morning without admitting a little air, and never admit much at a time. Up to the time of the colouring of the berries you will be constantly putting air on, and taking it off, especially during March and April to keep the temperature steady.

With regard to watering the borders those inside must never get dry. Give a little artificial manure—Thompson's or Wood's Le Fruitier are good—before finishing watering, to be gently washed down. Outside borders, except in dry summers, require less water, especially if covered with leaf mould or some other retentive material. As with inside borders we give a little artificial manure when watering the outside borders, which we find does good even when watering with liquid manure from farmyard.

And now a few words on stopping the laterals. In this important duty we must be guided by the distance between the Vine and by the variety. Varieties that show bunches at the third or fourth leaf may be stopped two leaves beyond the first bunch, while those that show bunches beyond the fourth leaf stop one leaf beyond the bunch; also those that are long jointed, for instance Cooper's Black, stop all laterals at the first leaf, and if there is not room pinch out all sub-laterals. Always remember that one well-developed leaf is worth half a dozen crowded leaves.—W. T., Ireland.

OBSERVATION.

A FEW lines on the above subject may be of interest, and at the same time convey a lesson to young gardeners. Observation; what is it? A dictionary will tell us "it is the art of fixing the mind on anything." How do we observe? It should be with a combination of eye and brain, but it is to be feared it is more often with the former alone. We see something done, and think no more about it. That is a mistake. We should strive also to understand, so as to be able to do it ourselves.

What are we to observe? Firstly the kitchen garden—the one great branch, and at the same time perhaps the most neglected. Could we but devote part of our spare time to the study of it, we should not only derive pleasure, but benefit in after life. Why not make a daily round of the kitchen garden, carefully noting the routine of work, make a note of the time of sowing seeds, and as the crops come to maturity note that as well? What a study one could get out of Brassicas alone, or the Pea for instance! Then there is another branch—outdoor fruit culture. How greatly we could benefit ourselves by studying the various ways of planting, training, grafting, and pruning, also observing the different varieties as they ripen in their season. And again there is the forcing of various roots, such as Asparagus, Rhubarb, and Seakale; also Mushroom growing—all too much neglected by us. Then again, what can be gained from visits to the flower garden? The different kinds of bedding in their season and the various styles, for we must not limit ourselves to observing one garden only. The Rose garden in itself would form a most delightful course of observation. The pleasure grounds too, what could we not learn from them? Would not the study of Coniferae, and various shrubs and trees, yield both pleasure and instruction?

The glass department demands much thought. There are the various kinds of plants, all worthy of observation. And fruit culture under glass is perhaps a greater subject still. Take a house from the time of starting to the ripening of the crop, look at the various stages of growth and their requirements. There is air giving, how observant we must be in that. And temperatures, too; we are told by one very able writer that this alone is one of the hardest lessons a young gardener has to learn. Writing of temperatures brought the stokehole to my mind. We should always do our best to have our fires clear, and the surroundings of the boiler as neat as circumstances will permit.—S. S.

[This contribution on "Observation" in the present series leads us to say that a great lack of that valuable acquisition—intelligent observation—has been revealed by several correspondents. In our issue of December 31st, 1896, page 632, we gave what we thought clear instructions for the guidance and benefit of earnest young gardeners. The majority have followed those instructions in the most admirable way; but a considerable minority have either not read them or soon forgotten what they did read. The result is that we have many contributions, and most of them good, which cannot be published. Some are written on both sides of the paper, others are too crowded for revision, while several have failed to write their names and addresses on their MS. All the conditions mentioned are simple, and compliance with them is necessary for purposes of publication. In the case of accidental omissions on the part of writers of notes which have not appeared, if the subjects are quoted, also names and addresses supplied, the MSS. shall be examined. We repeat that every young gardener who aspires to become a creditable writer should attentively read and preserve the article above referred to.]

FRUIT FORCING.

Cherry House.—The Cherry is very impatient of undue warmth in the early stages of growth, particularly when the ventilation is indifferently provided. This is a vital point as regards crop, therefore commence ventilating at 50°, allowing an increase of 15° from sun heat with proportionate ventilation, closing the house at 50°, 45° being sufficient by day artificially, and 40° at night. The trees advanced slowly from December are now unfolding their buds, those previously forced being in blossom, and will need attention in fertilising the flowers on fine days, using a camel's-hair brush, bunch of feathers, or rabbit's tail mounted on a small stick. Where the flowers are not expanded it is advisable to fumigate the house, so as to make sure that the trees are free from insects, repeating at intervals of a day or two. Examine the border to see that there is no deficiency of moisture, affording a thorough supply of water when necessary. Trees in pots will require more frequent attention. Any alterations in the way of introducing fresh trees must be completed without delay, and taking precautionary measures, so that shading may be applied to such trees whenever sunshine is powerful, and in order to promote the re-establishment of the trees they should be lightly sprinkled more frequently, and other surfaces moistened, but avoid making the soil sodden.

Cucumbers.—Young plants being now ready for transference to the hillocks in the Cucumber house, which, having been thoroughly cleansed and the soil placed in a few days previously to become warmed, they should be planted. Press the soil firmly about each plant; place a stick to each and secure it to the first wire of the trellis. If bright sunshine occur shade lightly in the middle of the day to prevent flagging, and after the plants become established it can be discontinued, subjecting the plants to the full influence of the sun. Keep the night temperature at 65°, 5° less on cold, but 5° more on mild nights, and 70° to 75° by day, with 80° to 90° from sun heat, closing early in the afternoon, with plenty of atmospheric moisture on fine days. Plants in bearing will need copious supplies of liquid manure in a tepid state. Crop lightly, and keep the plants clean. Avoid over-watering, keep the foliage thin, remove bad leaves and exhausted growths, stopping others one or two joints beyond the fruit as space allows, maintaining a succession of young growths for bearing.

Cover the lights of dung-heated frames with double mats at night, the linings of the beds being attended to weekly or fortnightly, according to the state of the weather, keeping a supply of well mixed manure and leaves in readiness for that purpose. (See Melons.)

Figs.—*Earliest Forced Trees in Pots*—Pinch out the points of the shoots when they have made five leaves. Maintain a steady temperature of 55° to 60° at night and 65° by day, advancing to 75° with sun heat, closing early and allowing an advance to 80° or 85°. In dull weather a little extra heat early in the day will allow of ventilation, if only for an hour or two, to give a change of air, which tends to solidify the growth. Keep the bottom heat steady at 70° to 75°, introducing fresh leaves as required. Red spider must be kept down by syringing, but always early in the afternoon, to allow the leaves to become dry before night. In dull weather it is better to damp the paths than to keep the plants constantly dripping with water, which hinders evaporation and prevents the elaboration of the sap.

Early Forced Planted-out Trees.—As these are growing maintain a temperature at night of 55°, and 60° to 65° by day, with a rise of 5° to 10° from sun heat. Syringe twice a day on bright days, but in dull weather morning syringing, with damping in the afternoon will be sufficient, ventilating freely on all favourable occasions, as a weakly growth cannot afterwards be made stout nor thin foliage become thick, therefore strive for sturdy growth, well developed, thick leathery leaves from the commencement. A little partially decayed lumpy manure placed on the border will attract the roots to the surface, whilst not depriving the soil of air, and water in a tepid state should be given as necessary, but avoid overwatering in the early stages, especially with liquid manure.

Second Early Forced Trees.—Where there is more than one Fig house with the trees planted out the second may now be started, and these will give a first and second crop of Figs. The trees bearing on the extension growths produce grand fruits, those having borne and become bare being cut out so as to give place to sturdy well-furnished growths, thinly disposed and kept clean. Bring the border into a thoroughly moist state by repeated supplies, if necessary, of tepid water or liquid manure. Syringe the trees occasionally, damping the paths twice a day. A temperature of 50° at night and 55° by day is sufficient to commence with, advancing to 65° from sun heat, ventilating freely on all favourable occasions.

Melons.—A brisk bottom heat is necessary in the cultivation of early fruit, and it should be durable. In houses hot-water pipes are unquestionably the best, but for pits and frames fermenting materials are relied on, and with good results. Stable litter and an equal proportion of Oak or Beech leaves should be thrown together about a fortnight before they are required, thoroughly incorporating them, and if dry they must be moistened. In a few days they will, if sufficiently moist

become heated, then turn the material before violent heat is produced, outside to inside, damping any dry portions, but in case the heating does not occur quickly the materials must be turned after a few days and receive water as required. In making hotbeds select a dry place or employ a layer of faggots for the foundation, taking care to make the bed large enough for the season; 5 feet high at back and 4 feet in front, with the material well beaten down, will not be too high.

Place the frame in the bed, and in four days or so level the bed if necessary by adding the requisite material, and place on the centre of each light about a barrowful of soil in the form of a flattened cone, the top about 1 foot, not more, from the glass. When the heat does not exceed 85° to 90° in the hillocks place a plant in the centre of each, pressing the soil firmly around the ball, taking care not to injure the stem, and a little dry soot drawn in a ring round each plant will protect it from slugs. The day temperature should be 70°, with 10° to 15° more from sun heat, losing no opportunity of admitting a little air to allow of the escape of rank steam or accumulated moisture, but in no case must air be admitted to lower the temperature below 70°. The night temperature should be 60° to 65°, 5° more in mild weather. The plants should be stopped at the second rough leaf for frames and pits. Instead of planting out too soon in houses shift into larger pots as required, securing the stems to small stakes and rubbing off the laterals to the height of the bottom wire of the trellis.

Pines.—The plants recently started into fruit will, if in good condition at the roots, produce strong suckers. When these are large enough to handle all, except one to each plant, should have the centres taken out in order to check the growths. To supplement the autumn-potted plants select others which have been wintered in 7 or 8-inch pots, choosing the most vigorous plants. The remainder of such plants should be reserved until the general spring potting, when they should be shaken out and treated like suckers. Procure fibrous loam with the herbage reduced, or if used fresh it should be placed where it can be heated so as to kill the grass and any larvæ or insects it may contain, and when torn up in suitable compost add a quart of soot, two of wood ashes, and a pint of superphosphate to each barrowload. If the loam has been laid up it must be had under cover some little time before using to become dried. Drain the pots moderately but efficiently, dusting with wood ashes or soot so as to exclude worms; and keep the plants well down in the pots, ram the soil firmly round the roots, leaving sufficient space to admit of copious supplies of water being given when necessary. For Queens 10-inch pots, and 11 or 12 inches are suitable for those of stronger growth. A temperature of 60° to 65° will be sufficient for these plants, also for those potted last autumn, and 80° to 85° at the roots.

Plants in beds about to be started into fruit must not have the heat at the base of the pots over 90° or 95°, or their roots will be injured. If sufficient fruit be started to meet the requirements, late successional plants may be advanced slowly, these with autumn potted suckers requiring careful watering, especially where the heat is supplied by fermenting materials.

Strawberries in Pots.—The earliest plants have thrown up trusses strongly, especially La Grosse Sucrée, Royal Sovereign, and Vicomtesse Hericart de Thury. The fruit having set freely and being well thinned are advanced in swelling. This should be accelerated in a temperature of 60° to 65° or 70° by artificial means, and 10° to 15° advance from sun heat, maintaining a genial condition of the atmosphere by damping and light syringing on fine afternoons. When the fruit commences ripening a drier atmosphere will improve the flavour and colour of the fruit. Plants advancing to the flowering stage must not be hurried, 50° to 55° being ample by artificial means, and 60° to 65° with sun heat and free ventilation, but avoid cold draughts, especially directly upon the plants, as these cause the young fruit to become brown and cease swelling. More plants should be started without delay, such varieties as Noble, President, Sir Joseph Paxton, Auguste Nicaise, James Veitch, Lucas, and Sir Charles Napier, affording grand fruit, introducing along with them some of the early varieties, such as La Grosse Sucrée, Royal Sovereign, and Vicomtesse Hericart de Thury, so as to secure the succession unbroken, and have high-class produce. Keep a sharp look out for aphides in the early stages, fumigating upon their first appearance, for they insinuate themselves into the opening buds, and give much trouble unless promptly destroyed; indeed good fruit cannot be had if the pests get a strong hold on the plants, and the time to destroy them is before flowering.

THE KITCHEN GARDEN.

Carrots and Radishes.—These can be forced together in the same frame or pit. Prepare a gentle hotbed of leaves and stable manure, or the latter alone. If frames are deep, after setting these on the beds half fill with some of the shortest of the heating material, raising to 6 inches from the glass with fine sandy soil. When all danger of over-heating is past open shallow drills 8 inches apart for the Carrot seed, and midway between these sow the Radishes. Sow the seed thinly, and cover with fine soil. The frame should be kept darkened and close till the Radish seed has germinated, after which admit all the light possible, and air whenever the weather is favourable. When the sun gains in power considerably ventilate freely, and keep the soil uniformly moist.

Cauliflowers.—Plants not protected have been much injured by the late frosts, but those roughly protected are apparently healthy. They do not transplant readily from either seed beds or where pricked out, moving best out of 3-inch pots. Now is a good time to place a portion or all of the stock in these pots, using rich loamy compost and potting firmly. Keep in gentle heat till the plants have rooted into the

fresh soil, after which they should be kept in cool frames or on greenhouse shelves till they can be planted out in hand-lights at the foot of south walls, or in other positions where they can be roughly protected when necessary. More seed should now be sown thinly in pans or boxes. Before the plants become drawn transfer to shelves near the glass in gentle heat. After they have formed rough leaves, either place singly in 3-inch pots or in pairs in 4-inch pots, sinking the stems to the seed leaves. Keep them in heat till well rooted, then arrange them either on a greenhouse shelf or in cool pits and frames. Duly hardened and planted out before they become root-bound these early raised plants will form a close succession to those raised in the autumn.

Celery.—If early Celery is wanted, seed of a good white variety ought now to be sown on the surface of fine light soil in pans, watering this before rather than after sowing, and covering very lightly with fine soil. Place in brisk moist heat, cover with a square of glass, and shade heavily till the seeds germinate. Raise the seedlings well up to the glass, and prick out in boxes or pans of rich soil soon after the rough leaf has formed on them.

Leeks.—If these are wanted extra fine early in the season seed ought to be sown at once thinly in a pan or box. It will germinate most quickly if subjected to a brisk, moist, bottom heat, subsequent treatment also to be the same as recommended for early Celery. For ordinary purposes the plants may be raised in the open, sowing the seed with the Onions early in March.

Lettuces.—Early frame-grown Lettuces are always appreciated. Sow the seed thinly in pans, and place in heat to germinate. Before the young plants become drawn move the pans to a swing shelf in warm greenhouse. If raised thinly there will be no need to prick them out, as small plants may safely be transferred direct to beds of rich soil. Hard forcing must not be attempted. Form solid hotbeds in shallow pits or in a sheltered position for frames, raising the 6 inches of rich loamy soil in these well up to the glass. Keep well supplied with moisture, and avoid undue coddling.

Onions.—If fine roots are needed for the August shows these are best obtained by raising the plants early in heat, duly planting out on firm rich ground. Onions treated in this way are also less liable to be destroyed by the Onion maggot, and the crops mature early, keeping well accordingly. Sow seed at once thinly in boxes of good soil to obviate the necessity for pricking out into other boxes later on. If possible place the boxes on a hotbed of some kind, and failing this in brisk moist heat, till the seed has germinated, raising them up to nearer the glass to prevent the seedlings from becoming spindly.

Tomatoes.—Strong young late summer raised plants in 10-inch or larger pots, or else planted out in ridges of soil, will soon be giving ripe fruit, and the flowers will also open and set more satisfactorily than during the duller days of early winter. If there is ample room reserve some of the side shoots which are constantly pushing forth, as these will give early clusters of fruit. If there are no fruit on the lower parts of the stems, remove the older leaves and lay in a young growth from near the ground. Top-dress and otherwise feed old plants, and these will also produce abundance of fruitful growths, the crops ripening well in advance of any obtained from plants raised early in the winter.

Raising Tomato Plants.—Seed ought always to be sown thinly in pans. It will germinate quickly in brisk heat, and the seedlings should be raised well up to the light and sunshine before they become drawn. When in rough leaf lift them out of the pans with a label, and sink them singly and up to their seed leaves in 2½-inch pots. Return to light staging or beds in a forcing house, and before they become root-bound either shift into 5-inch or slightly larger pots, or plant direct where they are to fruit. Extra strong seedlings may be placed in pairs in 6-inch pots, this obviating the necessity for a shift, but they must have the benefit of a temperature from 60° to 70°, and be carefully watered for a time.

PLANT HOUSES.

Chrysanthemums.—As these become rooted harden them if they have been under hand-lights, and place them on a shelf close to the glass, to prevent their being drawn up weakly. If in thumb pots be careful the soil does not become dry, and when the plants are well rooted transfer them into 2½-inch pots. They will grow sturdily if placed where the temperature does not fall below 40°. Cuttings must still be inserted; where the plants are required to produce large flowers place them singly in small pots. Those for ordinary decoration may be inserted thickly in boxes, and covered with a square of glass. Early and late flowering varieties are very useful where cut flowers are largely in demand. Good supplies of the former should be rooted; there is no hurry about the latter, and we rarely root the whole stock of these before March. As the old stools are thrown out wash the pots and store them away ready for the time when they will be wanted. A note should be made of any extra pots that may be needed, so that there will be no delay at potting time. Sort the stakes, and provide fresh ones in the place of those too short. If these are to hand they can be painted in readiness, while work outside is at a standstill.

Mignonette.—Fill 5-inch pots with a compost of three parts fibry loam, the other part being composed of leaf mould and sand with one-seventh of decayed manure. Make the surface even, and sow seed of a good strain evenly, cover the seed with fine soil, and water with a fine-rose can. If the pots are placed in a vinery just started the seed will soon germinate; gradually harden and place them on a shelf close to the glass, where the temperature will not fall below 45°. Thin out, if necessary, those raised from seed sown early in September. Keep these as cool as possible. If any of the plants are growing weakly pinch out the

points. Be careful that they do not become dry at their roots. Standards and pyramids, where the flowers are not needed, may be removed, and the growths tied down; give these a little artificial manure to the surface of the soil, water carefully, and keep the plants standing on a moisture-holding base.

French and Fancy Pelargoniums.—Pinch out the points of late-rooted cuttings and place them in 5-inch pots. Use for a compost fibry loam, sand, and one-seventh of manure. Place the plants on a shelf, keep them cool, and water carefully. Pinch all shoots on plants that need it that are not required for early flowering. Some of these will need repotting, and in doing this press the soil firmly to prevent soft leafy growth. All that is needed at present is to keep the plants slowly moving. Although they need careful watering do not keep them so dry as to injure their soft, active roots. Watch for aphides, and fumigate at once upon their first appearance.

Zonal Pelargoniums.—Bushy little plants in 3-inch pots may be placed into 5-inch size, using the compost advised above. Merely keep them growing, but do not pinch their shoots. As soon as the days lengthen they will bear gentle heat and come early into flower. Select from amongst those which have been flowering dwarf free-blooming varieties, and if these are given a little artificial manure and kept slowly moving they will not be long before they commence flowering again. Those that need cutting back should be kept rather dry. Place all that have done flowering and need pruning in a cool house, and give them little or no water; if cuttings are needed from them early they will root all the better and be much less subject to damp if moderately firm than if they are soft.

Calceolarias.—Give the earliest plants their final shift. Use a moderately light but rich compost, keep the plants cool and on a moisture-holding base. Repot successional plants as they need more root room. Do not allow them to become dry nor keep them in a dry atmosphere, or they will soon be attacked by aphides.

Cinerarias.—For those in small pots that are required for flowering in May a small shift only is necessary. Keep the plants cool, only be careful that the foliage does not suffer from damp. They will be safe in the greenhouse where fire heat is used to keep out frost and occasionally to expel damp. Give those which are throwing up their flower spikes soot water in a clear state.

Primulas.—Place in 3 or 4-inch pots those required for late spring flowering. Keep the plants cool, but in a position where they will be free from damp. If close or confined they suffer from damp, the foliage draws up weakly, and the plants flower imperfectly. Sturdy growth must be aimed at, and the result is abundance of large flowers.

Carnations.—Fumigate at once if aphides attack the points of these plants. Miss Jolliffe will continue to unfold its flowers if the temperature in which they are grown does not fall below 45° at night. Autumn rooted plants in small pots may be placed in the 5-inch size. Well-rooted layers of *Souvenir de la Malmaison* and other varieties may also be placed into 5 and 6-inch pots. If these are kept where frost can be excluded they will continue to root and make slow growth. Watch for any brown fungoid growth on these plants. Move those infested, and scrape out with the point of a knife every trace of the disease, and then dust the affected part with sulphur. If a solitary plant only is attacked it will be wise to burn it at once. A sharp look out should be kept for this disease; if allowed to spread it will quickly destroy the plants.

Lilium Harrisii.—Watch for aphides, which are liable to attack the points of the plants, and fumigate at once if they are observed. It is surprising how quickly they cripple the foliage. If the plants are not needed in flower quickly keep them close to the glass, where the temperature is about 40°. If given intermediate treatment they soon run up to a height of 4 feet or more. This cannot well be avoided if they are wanted in flower early. As soon as *L. eximium* has grown through the plunging material place the plants on a shelf close to the glass in a perfectly cool house. African-grown bulbs of *L. Harrisii* appear to be of larger size than those grown in America, and as they are issued about Whitsuntide they will prove invaluable for flowering during the closing weeks of the year.

THE BEE-KEEPER.

SEASONABLE NOTES.

PURE HONEY.

No apology is needed for referring to this subject, as it is of great importance to bee-keepers in this country. It is a fact well known to many people in the trade that there is a vast amount of foreign produce sold under the name of honey which has very little of the genuine article in its composition. That I am not alone in this opinion I may be allowed to make a few observations affecting this question on what has been done in Belgium.

According to a correspondent the Belgian authorities have set an example which might with advantage be followed in this country. The large imports of honey in a more or less adulterated state greatly interfere with the sale of the genuine home product, and therefore hinder the development of bee-keeping for commercial purposes. The Government of Belgium has promulgated

a decree as to what is to be considered honey, and regulating the sale of this commodity. Under this decree, says a contemporary, the denomination "honey" is to be applied solely to the substance produced by bees from the nectar of flowers or other juices gathered from plants. Honey produced by bees fed with other substances (excepting such as are supplied to them as provision for winter) must bear a denomination indicating the material given to the bees, as, for instance, "honey from sugar," "honey from glucose," or "mixed honey."

Honey substitutes and mixtures of honey with such substitutes or with other foreign substances must be denoted "artificial honey," or honey mixed with such and such substances, or some term not involving the word honey must be used.

The sale of honey containing more than 1 per cent. of pollen, wax, or other substances insoluble in water, or more than 0.5 per cent. of mineral matter, and all spoilt honey is prohibited.

Vessels containing honey or mixtures of honey must be labelled in such manner as to specify the exact nature of the contents as defined by the present decree.

If something like the above could be carried out in this country, what a boon it would be to bee-keepers throughout the length and breadth of the British Isles!

Honey placed on the market by bee-keepers who have a reputation to lose may always be depended on. As a proof that it is the foreigner who glutts our market with the spurious concoction, I may state that a few years ago a well-known analyst examined upwards of twenty samples of honey obtained from various sources, with the result that all the samples of English honey were found to be pure, but the foreign, without exception, was adulterated. Some of the samples experimented on had no honey whatever in its composition. I do not wish to give the impression that I consider all foreign honey to be adulterated, as one sometimes meets with some really first-class samples; but the above shows that it is largely adulterated, as the samples under notice were obtained from all possible sources.

As showing the amount of honey that is annually imported into this country I may say that during the past year, according to a return furnished by the Statistical Office, H.M. Customs, honey to the value of £29,296 was imported. Although great strides have been made in apiculture during the past quarter of a century, and hundredweights of honey are now gathered where none was obtained before, still there is not sufficient for our requirements, as the above figures show. Let us endeavour, then, to place the produce from our apiaries before the public in such a manner as will claim attention. All sections of comb honey should be well sealed over, and if glazed it will prevent them being damaged when handled.

Run honey should be put in 1 lb. glass jars and neatly labelled with the producer's name and address, which will be a guarantee of its purity. Honey of inferior quality should not be offered for sale, but given back to the bees for storing purposes. By this means bee-keepers may create a ready market for their produce at remunerative prices, which will benefit themselves as well as the consumer, who will thus obtain the genuine article.

If bee-keepers as a body will work on these lines they may before many years hope to have a share of the large amount of capital that is now paid to the foreigner for honey and its substitutes; but it is only by paying close attention to detail that we can hope to succeed.

STORING HONEY.

Some bee-keepers have a difficulty in keeping their honey in good condition. With run honey it is not so difficult, but with honey in the comb the case is different, and what is more discouraging to the beginner on examining his sections a few weeks or months after storing them for future use to find them all leaking, although they were well sealed over. This is usually caused by storing in a low damp atmosphere. They are then useless except for home consumption, and even then the flavour is not first-class, reminding one of fermented honey. If allowed to remain in this state for several months much of the product will granulate, and is then of but little use.

Honey to be kept in prime condition should be placed in a temperature of about 50°; a few degrees more or less will be of no consequence if the atmosphere is dry.

A room in which there is a fire daily, or occasionally, will keep comb honey in admirable condition. I have occasionally kept sections of honey for two years, and after being kept for that length of time it was difficult to distinguish them from those just removed from the hive.

All sections should be kept free from dust or they will soon become disfigured. A high temperature will usually prevent run honey from granulating; but I do not see what advantage there is to be derived from doing so, as honey may be made liquid at any time by placing the vessel containing it in hot water for a few minutes.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

W. Atlee, Burpee & Co., Philadelphia.—*Seeds*.
 Kerr Brothers, Dumfries.—*Seeds and Roots*.
 The Surrey Seed Company, Red Hill.—*Seeds*.
 E. Webb & Sons, Wordsley, Stourport.—*Farm Seeds*.

* All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Errata.—In the reply to "P. H.," second column, page 84, tenth and eleventh line of paragraph, for "3½ lbs. kainit per square yard," please read 3½ lbs. kainit per square rod.

Boards for Exhibiting Grapes (Z.).—If you refer to our issue of July 23rd, 1896, you will find the information you require. The copy may be procured from our publisher for 3½d., post free.

Hard Water for Tomatoes (T. P. R.).—Hard water is not injurious to Tomatoes unless the lime exist in excessive amount, but it is well to have the water exposed to the air for some time before use so that it may become warmed to at least atmospheric heat at the time of using. If the water is too limey soften it by the use of anti-calcaire, 1 lb. to 250 gallons of water, mixing well and allowing it to stand twenty-four hours, then employ the clear water only; or dissolve 1 oz. of washing soda in a gallon of hot water, which add to 9 gallons of the hard water, and so on in proportion. Allow it to stand twenty-four hours, then use. This seems to suit Tomatoes.

Medals of Honour (H. C.).—We have received the paper cutting that "amused" you. The paragraph was no doubt written to amuse, and thus served its purpose. We have no desire to find fault with it. The whole question is one of individual taste, as bearing on the vanities of the world. Some persons like to be awarded cups and medals, others do not equally value them. Some persons like to be addressed as "Esquire" who have no legal right to the title, others of the same status being well satisfied with the plain "Mr." Some who regard medals as mere bangles are willing to pay for the luxury of attaching distinctive letters to their names, and for cockades on their coachman's hats, while others care for none of these things. It is a question of idiosyncrasy. No doubt there are plenty of vain people about, but small, we think, fear of England becoming a nation of popinjays.

Paradise Stocks for Transportation to the Western Coast of America (Pacific).—So far as we know seeds or "pips" of Paradise stocks are not procurable; they could not be relied upon if they were, for the several forms of Paradise stocks are selections of species or even varieties, hence must be perpetuated by layers or other similar methods. The French Paradise is too tender for this country, therefore the broader leaved English and the Nonesuch Paradise varieties are those commonly used as dwarfing stocks. Stocks raised from pips, transplanted the first autumn, and allowed to grow a year, are ready for working in the following season. Stocks are readily transported to America, and can be had of most large nurserymen at a low price per 100 or 1000.

Cypripedium Leaves Rusted (F. S.)—The leaves are not infested by any insects or fungi, at least we failed to discover any, and though the appearance is that of attack from eelworms our efforts to find them were futile. Indeed, beyond the cells being yellow and having every characteristic of Plasmodiophora infection, there was nothing discoverable in the tissue. This form of "rusting" is said to arise from a chill, and not to be connected in any way with micro-organisms or anything of a parasitic nature. The cells are ruptured by some agent, possibly that of water long remaining on the leaves, or from its containing some noxious substance, such as that of iron. There was a slight clamminess on some of the spots, and in these decayed parts several micro-organisms of a septic nature. We can only suggest the careful use of soft and properly warmed water, not pouring it so as to lodge on the leaves more than can be helped. In a similar case we found sponging the leaves carefully with methylated spirit diluted with an equal amount of water of great benefit, but we rather incline to the view of the water being at fault.

Old Plane Tree Stem Covered with Ivy (G. B. T.).—The Ivy is a parasite of support, being indebted to the shrub or tree for the power to carry its stems and leaves upwards, also in due course its flowers, where they may spread in sight of the sun, its own frail stem being unequal to the burden; but it takes nothing, though it has suckers, from its neighbours or supporting tree. Its effect, however, is to overgrow and interfere with the vigour of the shrub or tree it grows upon, ultimately smothering it, which in the case of an old tree is a great ornament and not materially prejudicial, as under any circumstances the tree would gradually decline, and the Ivy would enhance its antique appearance, it increasing in vigour and beauty as the Plane tree became older. Even after the Plane died the Ivy would be a very desirable object, therefore we should not interfere with it under the circumstances. It is different in the case of a young or thriving tree, then the Ivy should be cut away, so as not to interfere with the growth, thus securing fuller development, as nothing can well progress with a heavy burden besides its own to bear, being more or less deprived of air, and to some extent moisture by the overgrowing plant.

Grafting a Camellia (Amateur).—As a rule, grafting plants is an operation best left to those who have been rendered expert in it by long practice, but the engraving (fig. 26) will show you how to do it. The scion is cut half its length wedge-shaped, leaving on each side an equal breadth of bark diminishing gradually to a point. The stock (B) is slit at b by a single cut of the knife, the blade penetrating the alburnum. The scion (A) is introduced by its base a, then tied as represented at c. If this is

FIG. 26.—GRAFTING A CAMELLIA.

done in the open air it must be covered with wax or clay, because the cut on each side of the slit leaves an opening. It is not necessary to cut off the top of the plant when the operation is completed. The work is done at almost any time in the spring.

Diseased Onions (S. H.).—The Onion is infested by the Onion mould or fungus, *Botrytis galanthina*, Sacc., this being found on Snowdrops and other bulbous plants, such as Lilliums, and is the conidial condition of *Sclerotinia bulborum*, Rehm. This springs from a sclerotium formed in the rotten bulb or on it, and even in the ground, and bears the ascophores or spores in asci, and resembles a minute disc-like Toadstool. There are myriads of the *Botrytis* spores on the specimen. It and all like it ought to be burned to prevent further contagion. Infested land should be well dressed with lime, and Onions not grown therein for some time. But the fungus is also a saprophyte, very common, yet a very malignant parasite at times, sometimes ruining the autumn Onions wholesale when fit for pulling, or should be, and not unfrequently attacking the spring-sown ones, and sweeping them off when the maggot also "bites"—that is, in early summer, generally in late May or early in June, and onwards. Dusting with a fungicide in powder is the best preventive, but it is necessary to begin in time. We have also found permanganate of potash useful, and it is not likely to lead to any danger to human life. The permanganate should be diluted to a deep rose colour (2 fluid ozs. to a gallon of water), and applied by means of a spraying apparatus when the Onions are a few inches high, say when 6 inches, repeating occasionally. Probably

the attacks of the fungus are a consequence of neglect in the proper rotation, the land being positively a festering mass of organic matter of the kind affording the essential food. Anyway, change of crops, if only Parsley, is a great hindrance to it. Sometimes it acts wholly as a saprophyte for years, then for some unknown reason wakes up, and shows what it can do as a parasite, assailing the bulbs in summer when ready to pull, cutting off the leaves, entering by the crown, and so feasting on them in store, going rotten, as the saying has it, "without reason."

Dahlias (Amateur).—Twenty excellent Cactus Dahlias are as follows:—Charles Woodbridge, bright crimson; Fusilier, salmon pink; Mrs. Fell, white or cream; J. E. Frewer, vermilion; Royal George, carmine pink; Lady Penzance, yellow; Valkyrie, cardinal, shaded rose; Miss A. Jones, crimson scarlet; Miss Nightingale, yellow ground, edged with scarlet; Mrs. Wilson Noble, rosy pink; Mrs. Gordon Sloane, terracotta pink; Harmony, bronze; Matchless, maroon; Mrs. Barnes, primrose; Bertha Mawley, cochineal; Cycle, magenta; Harry Stredwick, fiery crimson; Cinderella, plum; Starfish, vermilion; Mrs. Kingley Foster, golden amber. The last five varieties are new, and will be distributed this year at probably 7s. 6d. each. Should you not wish to give so much the following varieties would be good substitutes:—Earl of Pembroke, Gloriosa, Major Haskins, Delicata, and Mrs. Leopold Seymour. The National Dahlia Society's schedule gives a list of true Cactus varieties, but by a resolution passed at the last meeting the term decorative is dropped, so that any variety not named in their list is debarred from competing at their exhibition. For list apply to Mr. J. F. Hudson, Gunnersbury House, Acton, who is Secretary of the Society now. Subscribers of 5s. are members of the N.D.S.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (P. Hargreaves)—1, Bess Pool; 2, Blenheim Orange; 3, Bramley's Seedling; 4, Tower of Glamis; 5, Red Winter Calville. (C. A. S.).—1, Golden Winter Pearmain; 2, American Mother; 3, Queen Caroline; 4, Cox's Orange Pippin; 5, Winter Hawthornden; 6, Alfriston. (G. S.).—1, Nec Plus Meuris; 2, Josephine de Malines; 3, Chaumontel. (J. O.).—1, Lane's Prince Albert; 2, Wellington. (W.).—Unknown.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (F. J. B.).—1, *Euonymus latifolius variegatus*; 2, *Abutilon vexillarium*; 3, *Cyperus natalensis*; 4, 5, and 6 dead. (W. White, Grantham).—1, *Selaginella cæsia*; 2, *Panax Victorice*; 3, *Eucomis pallidiflora*; 4, *Trichomanes radicans*; 5, *T. reniforme*; 6, *Euonymus radicans variegata*. (A. C.).—1, *Cypripedium villosum*; 2, *Odontoglossum Rossi majus*; 3, *Cymbidium tigrinum*. (Kate).—1, *Eranthemum pulchellum*; 2, *Libonia floribunda*; 3, *Cyperus alternifolius*; 4, *Lælia anceps*, poor form; 5, *Cypripedium Harrisianum*.

POULTRY AND EGGS IN 1896.

THE year 1896 has closed, and we are now in a position to see where we stand with regard to food imports. Do we ever quite grasp the fact as to how much money goes out of this country to pay for goods which might to a much greater extent be produced at home?

There are, of course, many things that must come from abroad, articles that cannot, from climatic reasons, be grown here; and even of those things that we can produce, our population is such a teeming one that by no known means can we produce enough. But again, we cannot help thinking we take many matters too easily. We don't seize our opportunities; we don't believe (or if we believe we don't practise) that proverb about the nimble sixpence. The industry that we have now in mind is the poultry industry. The statistics of the poultry and eggs imported during last year are now before us; they are very astonishing, and to the unprejudiced mind furnish much food for reflection.

A few figures will elucidate matters.

	1894.	1895.	1896
Eggs	£3,786,329	£4,003,446	£4,184,567
Poultry and Game	480,884	605,160	605,458

How do these figures strike the reader? Nearly £5,000,000 for poultry and poultry produce in one year! Are we more luxurious than other nations, and demand, as common articles of diet, what they treat as delicacies, and are ready to turn into money; or are they really superior to us at the work of production, and so send us only their surplus? We rather fancy both causes are in operation. When trade is good no people live so well as our middle and lower classes, and our tendency has ever been prodigality in cooking—the best of everything, and plenty of it.

We are not, as a whole, a saving nation, and we most certainly

are fond of good living, though behindhand in the art of making that good living at little cost. To begin with eggs. Where do they come from, and what is their respective value?

Russia	15	per cent.	5s. 2½ d. per 100.
Denmark	12½	"	6s. 8d. "
Germany	19	"	5s. 4d. "
Belgium	16½	"	6s. 2½ d. "
France	30½	"	7s. 7½ d. "
Canada	4½	"	5s. 1½ d. "
Other countries ...	2½	"	6s. 4½ d. "

Canadian eggs come 4000 miles, and those Russian eggs from the Volga district have to travel 1000 miles before being shipped from one of the Baltic ports. Great as is our import of French eggs, yet it is over £250,000 less than it was a few years ago, although they are gradually recovering their lost ground. Russian poultry and game imports are increasing enormously. In 1894 the value was £43,289, in 1895 £85,697, and in 1896 it rose to £143,584. Belgium and other countries are increasing their supplies, but the French supplies were much less, to the extent of £59,000 as against 1895, and £20,000 as against 1894.

At Newhaven and Southampton were landed for our Christmas market 2458 and 238 tons respectively of poultry from Normandy and Brittany. These weights would represent about 600,000 birds. As to our own statistics we have no reliable information. There has been a movement in the right direction, but poultry keeping in England is still in its infancy. This last has not been a good year for the poultry man, the excessive drought in the earlier months caused a great lack of natural food, and the heat was most trying to young poultry, especially to ducks. In our own case the field where we usually put our freshly hatched chickens was as bare and brown as the high road, and we had materially to increase the quantity of hand food to make up for deficiencies.

Birds did not grow well, and then came a long, wet, cold autumn, and the egg record has proved a bad one. There is one little fact to which attention cannot be drawn too often—the existence of so many aged hens. Hens over three years old are useless save for the broth pot, but hen wives seem very reluctant to part with these old birds, and thus give more room to profitable stock. Our experience is that after moulting hens can readily be sold for 3s. per couple, and even if less has to be taken they must at all risks be got rid of.

We also see on many establishments what we can only designate as mongrel stock. If the owner would make up his or her mind as to whether eggs or fat fowls were to be grown and arrange accordingly much better results would be obtained.

We do not care to grow more fowls than will supply us with young pullets and a few cockerels for table purposes, as we find the egg trade the best paying, sending them off to a large manufacturing centre.

Of course the best-laid schemes often go amiss, and we find to our chagrin that more cockerels are hatched than pullets. A fattening establishment has been started in our neighbourhood, and if the fowls are bred on certain lines—i.e., Indian Game-Dorking, the manager is always a ready buyer. We see these establishments are on the increase, and must be of material benefit to the ordinary farmer. He has no appliances for perfecting the finished article, and it will pay him better to sell off his stock when young.

We have seen much good result from a course of intelligent poultry lectures; but, alas! some of the lecturers have missed their vocation, and do more harm than good. As we said before, we are still, as a nation, very ignorant on this subject of poultry, but we are showing ourselves willing to learn, and that is a step in the right direction.

We are glad to see the railways are doing their best to bring the producer and consumer more into touch by lowering the rates; but strange though it may appear, there are still vast districts that the railways do not touch, and in these districts, owing to the difficulty of transport (save by carriers' carts once a week), poultry produce is very cheap.

In two such districts, personally known to us, there is more than a talk of light railways; if they become a reality they will do much to developing industries hitherto dormant.

We think the labourer and artisan (that is, in the rural districts) are not quite awake to the possibilities that lie at their door. If each did his utmost in poultry raising a nice sum might be added to the weekly income, and the foreigner get less of our hard earned cash.

WORK ON THE HOME FARM.

Mildness has suddenly changed to snowstorm and blizzard, and we are beginning to speculate as to damage to roots still in the ground, and are even fearful as to the safety of those in the pits. The extreme wet has saturated the Potato pies to such an extent that it is more than likely that the severe frost, accompanied as it has been by a driving wind, has penetrated to the tubers, and we expect to hear of a good deal of frost damage. Ploughing is now quite impossible, and if there is no carting of manure or refuse left on hand the horses must perforce have a rest.

The breeding flock now requires special and urgent attention. Frozen Turnips, or grass covered with several inches of snow, and, therefore, not easily accessible, are not enough in themselves for sheep with more than one life to provide for. Ewes, we think, require dry and nutritious food in any weather during pregnancy, but especially so in a period of frost and snow. Malt culms are an excellent food for lambing ewes, and they leave a considerable residual value in the manure. Dried grains are also very valuable; both these foods contain very little water, and are, therefore, particularly useful when natural foods are so watery and cold. If the flock owner is fortunate enough to possess a good supply of hay or seeds he will need no artificials, only a good hayrack or two to economise his fodder. Cattle are now all in the yards. They are doing well, but bedding is scarce and must be economised, so we cannot make them quite so comfortable as we should like. An increased allowance of cake has been found necessary; it will be discontinued when milder weather comes.

This is a good opportunity to make up arrears in the way of scotching or plashing hedges, and making up gaps. The fields of young seeds require special attention as regards gaps. It is a nuisance to have these things to attend to when the day for stocking arrives. A rail and a few long pales make the best stopgap, and they do not interfere with the after-growth of the hedge. Pales should be at least 4 feet long, better still 4 feet 6 inches. They should be driven well into the ground, and the rail securely nailed to them 9 inches from the top. Ordinary forged nails are the best, as they clench well, which wire nails do not.

OUR LETTER BOX.

Poor Soil and Best Means of Cropping (Faithful).—1, If there is a good plant of grass, why waste seed in renovating? Top-dressings, as advised in our previous reply, would pay better, and be more certain, as the young seeds might all perish amongst the grass. 2, The sooner kainit is applied the better. Sow it broadcast at once. The rain when it comes will wash it in. As regards planting fruit, your soil seems more likely to grow Plums than Apples or bush fruit, though possibly free-growing Apples would answer, and we know of excellent crops of Strawberries being grown in very sandy soil. But observe how fruit trees fare on similar land in the neighbourhood; also, the condition of hedges and forest trees will be a guide as to the prospects of success in fruit growing. You must have absolute security of tenure before planting fruit. Greens might do planted between the rows of second early Potatoes, but the later kinds would smother them. The best artificials for Lucerne are superphosphate of lime and kainit, 3 cwt. of each.

REMARKS.

24th.—Bright and sunny throughout.
 25th.—Fine early and at 9 A.M.; snow at intervals; dark and overcast night.
 26th.—Fair early; sun at 8 A.M., and bright and sunny throughout; fine bright night.
 27th.—Bright and sunny throughout; dull and overcast about 5 P.M.; fine night.
 28th.—Fair early; faint sun in morning; overcast and dull in afternoon; fine night.
 29th.—Fair early; overcast at 9 A.M., bright at 11 A.M. and throughout; overcast evening, with rain about 10 P.M.
 30th.—Rain from 5 to 9 A.M., overcast after; rain at 1 P.M., and dull afternoon and night.
 Another cold week, but not so cold as the previous one; bright warm sun on several days.—G. J. SYMONS.

NOW READY.

BARR'S SEED GUIDE

For 1897.

Barr's Seed Guide is full of practical hints, and is invaluable to Gardeners, Amateurs, and Exhibitors.

FREE TO INTENDING PURCHASERS.

VEGETABLE SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Select List of the Best Vegetable Seeds for securing a supply of Vegetables "the year round."

FLOWER SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Choice List of the best Seeds for the Flower Garden and Greenhouse.

ALL SEEDS CARRIAGE PAID ON RECEIPT OF REMITTANCE

We guarantee all our Seeds to be of the finest selected strains, and of highest growing quality.

FOR PRESENT SOWING,

AND

BULBS AND PLANTS

FOR SPRING PLANTING.

COLLECTIONS OF VEGETABLE AND FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM, HOLLAND, or to our General Agents,

Messrs. MERTENS & CO.,

3 CROSS LANE LONDON, E.C.

No. 868.—VOL. XXXIV., THIRD SERIES.

Barter's TESTED SEEDS.

A FEW MORE
New and Improved Vegetables.

CARTERS' OUTDOOR TOMATO.

The very best for open-air cultivation we know of. Should be grown by everybody.

In Sealed Packets, price 2/6 each, post free.

CARTERS' LEVIATHAN BROAD BEAN.

The longest-podded Broad Bean grown; fine for exhibition, and one of the best for cooking purposes. We have seen pods 21 inches long.

In Sealed Packets, price 1s. 9d. per pint; 3s. per quart, post free.

CARTERS' RED ELEPHANT CARROT.

A veritable giant, both in length and rotundity. Specimens exhibited at our establishment measured 2½ feet in length.

In Sealed Packets, price 1/6 each, post free.

CARTERS' EXTRA EARLY AUTUMN GIANT CAULIFLOWER.

This magnificent variety is more dwarf, considerably earlier, and altogether better than the old form. Grown in large quantities for Covent Garden Market.

In Sealed Packets, price 2s. each, post free.

CARTERS' SOLID IVORY CELERY.

Still maintains its position as one of the best white Celeries in cultivation. A customer writes:—"It was the only Celery we found good at the break-up of the intense frost."

In Sealed Packets, price 1/6 each, post free.

CARTERS' MODEL CUCUMBER.

Many so-called new Cucumbers are brought forward every season, but little is heard of them afterwards. This fine variety still maintains its position as the handsomest in shape, the best in flavour, and the finest in cultivation.

In Sealed Packets, price 2/6 and 3/6 each, post free.

CARTERS' RECORD ONION.

The largest Onion grown. A customer writes:—"I cleared the whole roost in the Onion competition with 'Record.'"

We have seen a specimen bulb that weighed 4½ lb.

In Sealed Packets, price 2/- each, post free.

THE CARTER SPINACH.

Mr. A. PETTIGREW, Head Gardener to the Earl of Bute, writes:—"The best Spinach in cultivation: quite distinct from all others." Award of Merit, R.H.S. trials, 1895.

In Sealed Packets, price 2/6 per pint; 6d. per oz., post free.

Illustrated CATALOGUE, Gratis and Post Free.

THURSDAY, FEBRUARY 11, 1897.

LEEKES FOR EXHIBITION.

THE Leek plays an important part nowadays in the economy of the kitchen, being used as a separate dish, and not, as formerly, simply for flavouring. The culture of the Leek for exhibition is an important operation, requiring great patience and considerable skill. Nowhere are Leeks so well cultivated as in the north of England and in Scotland. In some of the Northumberland and Durham villages and towns there are Leek clubs, and the annual competitions are keen and exciting. The following method is the one usually followed in the north, where length of blanch is more sought after than thickness, as in the south.

The seeds are sown early in February, in 2-inch pots, filled with a rich compost of good turf and decayed manure, these being plunged in a bottom heat of 70°, or 80° if attainable. Three seeds are placed in a pot, covered over, and in three weeks the plants will be large enough to thin out, which should be done by taking away the smallest, and leaving the largest plant in the pot. In about another three weeks from this time they will be ready to be moved into 3½-inch pots, using the same compost, and being careful it is well warmed before using. Replace the pots in the bottom heat, shading from bright sun.

If they can now be plunged in a bed with a few inches of manure on it they will be greatly benefited by the rising ammonia, while the manure helps to keep them moist. Syringe the plants now regularly night and morning, and the more moisture kept in the house the better for the Leeks. When the pots become fairly filled with roots they should be watered twice a week with sulphate of ammonia, in the proportion of quarter oz. to the gallon of water. If time and space permit, it is best to give them another shift into 5-inch pots, three weeks after the first potting, as this prevents any check. At the end of April remove the plants to a frame where they can be supplied with a little bottom heat, and gradually expose the tops to the air.

In a week if the weather be favourable they will be ready for planting. Dig out the trench 1½ to 2 feet deep, and pass the soil through a three-quarter inch sieve to remove the stones

and lumps of earth. Place this soil on each side for earthing up in due course. This trench should be filled 6 inches deep with good manure, fresh horse droppings if obtainable, but if not, any good manure will do. Cover over with 4 inches of soil, and plant the Leeks carefully in the trench. If fresh manure is used care must be taken not to place the roots too near it. Place some soil up the stem of the plant immediately, so that the wind will not damage the blades.

Some brown paper must be wrapped round the stem, and drawn up as the earth is gradually raised in the trench (paper collars can also be bought ready for the purpose). Before earthing see that the plants have a thorough soaking with water. Many people place drain-pipes a yard apart up the centre of the trench, and apply the water and liquid manure through the season in this way.

The proper length of blanch on a Leek is a matter of opinion, but 14 inches, with stem of medium thickness, is quite sufficient. One occasionally sees them blanched 16 and 18 inches, but they are then too thin to be handsome. In lifting the Leeks for show great care must be taken not to break the foliage. Everyone should be tied just above the blanch with raffia, and the outer leaves must not be stripped off excessively or the smooth surface so desirable will be lost.

Those who cannot raise the plants themselves can purchase fine ones ready for planting in May. The writer grows some thousands every year, and the growing of Leek and Onion plants for competition is in more than one Scotch nursery quite an industry.—S. J.

HARMFUL AND HARMLESS GARDEN MOTHS.

INTRODUCTORY.

To most gardeners moths of varied sizes and colours rank amongst the familiar winged insects, since they are seen both by day and night, also during the greater part of the year. Indeed there is no month when we may not chance upon a moth, either hibernating or performing its usual movements at a season when insect life is generally quiescent. So the moths of the *Hybernia* family, some of which are parents of very destructive caterpillars, have their time of emergence in the winter months, from November to February. Again, though moths are regarded rightly as night fliers by general habit, many fly by daylight, and of course some are dislodged from places where they have settled for the day, by various causes. It may be well to mention this, because people suppose that in the order to which moths belong they are distinguished from their relatives the butterflies by being lovers of darkness. Butterflies, however, do give preference to daylight and sunshine; one seldom moves after 5 P.M. even during summer, but I have seen red admirals sometimes careering about in the evening eager to regale upon fallen fruit.

Often I am asked for some simple distinction between moths and butterflies, for there are moths quite as brightly coloured as any butterflies, and some of them are slender-bodied—in the group of loopers or geometers, for instance. One of the best is to be found in the antennæ or horns, which amongst butterflies are knobbed and enlarged at the tips and always extended in front of the insect if settled, while moths usually lay theirs over the wings or bend them round. Also a butterfly, when resting, closes the wings above the body, which a moth never does. I have found it necessary to shield the majority of butterflies from a suspicion of being parents of insect foes, since in Britain we really have but two species that can be said to be injurious to cultivated plants. The rest are chiefly visitants to gardens, where some of them help forward fertilisation by moving from flower to flower. Newman, it is true, relates that when he was a young entomologist he chased clouded yellow butterflies in market gardens at New Cross, and was himself chased by the workers there, yet those butterflies had not bred on the spot, they came from Lucerne or Clover fields a little distance off. The comma butterfly has been bred upon the Red Currant, but it is a scarce and local.

Some of the Fritillaries, the caterpillars of which feed upon *Violas*, have been put on the list of garden enemies; the zeal of entomologists, however, has now made them too rare for any mischief to be charged upon them. Then there is the black-veined white, which on the continent is really damaging to fruit trees; but in Britain the caterpillars, by no means common, have only occurred on the Hawthorn. It comes to this, that our sole butterfly pests are the large, or Cabbage white, and the small white, both

abundant; the first, as the name implies, chiefly infests various Brassicas, though occasionally the caterpillars abound on other plants, the *Tropæolum* for example. The second, even more numerous, affects all sorts of Crucifers in gardens, not limiting itself to these, since it is frequently found upon *Pelargoniums* and various species; from their size and colour they frequently escape notice during the caterpillar stage.

Returning to our moths, without question the history of common garden species is to many gardeners not clearly outlined, judging from the information that is sought by some of my friends, and the appearance of occasional rarer kinds is also perplexing to them, thinking, perhaps, they are pioneers of a new foe. Others, however, seem disregardful of all moths, not connecting them with the caterpillars from which they have developed, and let them go their way indifferently. Now it is not to be expected that every gardener should be an entomologist, but some amount of book and practical knowledge about insect life is profitable to all. Besides, having such opportunities for observation, a gardener may render material aid to natural science.

One of the correspondents of this Journal discovered a curious fact which had escaped the notice of entomologists, that the wingless females of the winter moth (presumably of others, too, belonging to the same genus, *Hybernia*) are enabled to reach the higher branches of trees for the purpose of oviposition, by the aid of their male companions. People have asked me if moths "grew" after they appeared as moths, and whether they "bit" the petals of flowers to which they resorted. Again, did moths, like some blowflies and the aphid tribe, produce live offspring? To all three queries the answer was a negative. One day a friend stood with me watching a moth that was expanding its wings, having just emerged, and he was surprised to see it eject a large drop of reddish brown fluid. He asked if this would be at all harmful to any vegetable object it fell upon. I said it was not probable that it could be, there being no great quantity. Still, there had been times when from the emergence of a goodish number of moths on the same days, gardens and fields were noticed to be besprinkled with such spots. By our forefathers the true cause was not detected, and it evoked some superstitious idea of the falling of bloody rain.

Shakespeare puts into the mouth of a well-known character of his, words expressing suspicion of lean men, as far more likely to be dangerous than their fat brethren. Now, with regard to garden moths, it is certainly the fat ones that are prominent foes to vegetation, though thin-bodied species may be mischievous, such as the Gooseberry moth and the garden carpet. It is to the group which, according to the old classification, is called the *Noctua* tribe, fat-bodied moths, that the greater number of our enemies belong; they are parents of the mighty army of surface caterpillars. In our islands we can reckon up something like 300 species, but, of course, many do not occur about gardens, and some that do have caterpillars comparatively harmless. A few of these moths fly by day, such as our lively friend the Gamma. The majority repose with the upper wings folded over the lower pair. They have long antennæ, and their colours are generally browns and greys, some having brighter tints; the under wings seldom have any markings.

Sweets of any sort have great attractions to these moths, and it is to entrap them that the entomologist spreads upon trees a cunningly devised compound before twilight, which he visits or watches till the early morning hours, seeking for rarities. He may get them—sometimes; but he is frequently disgusted by a rush of common species, the well-known Cabbage moth, for instance, and its brethren. Might it not be a good plan for a gardener to get rid of some of his enemies by capturing them with sugar before they have deposited their eggs? These, and also the young caterpillars, are not easily discoverable as a rule, and when older they often conceal themselves. Various are the recipes for this moth-snaring syrup, which might be spread on walls or palings as well as trees. Some flavour it with rum or aniseed, but really nothing is more fetching than ordinary Jamaica foots.

It is a sight to see moths hovering over this bait, their eyes frequently gleaming like tiny stars in this phosphorescence or electricity, or neither. Possibly they emit a portion of X rays, as the glowworm's light is found to do. No doubt the large hawk moths, which occur in gardens now and then, look formidable insects, and their caterpillars are hearty feeders; but they are not plentiful enough to make trees or shrubs appear the worse for their attacks, or rarely. By far the preponderance of our moths are not only slight in form but small in size; the many of the tortrix tribe with bell-shaped wings, which, when caterpillars, exercise their skill in rolling or contorting leaves, and the still less tineæ species of varied habit. Some of the little moths are so numerous that their caterpillars can do more harm than we should suppose; fortunately they are much sought by insect-eating birds.—ENTOMOLOGIST.

HOW TREES ARE BUILT.

It is generally known that the cone is the strongest structure in Nature. Trees may be regarded as arborescent cones, for if we examine the stem and branches of them when denuded of the leaves we perceive at once that they are so constructed. The main stem is broadest at its base, and decreases gradually towards the ends of the branches. A branch in the side place, where a side branch starts from, is thicker than the side branch, and this in turn is thicker than the branchlet it produces. In this way the thickness of the main stem steps away, so to say, by degrees from branch to branch, finally losing itself almost in the thin branchlets of the latest shoots.

A transverse section of a Beech tree, for example, shows a number of concentric and almost circular beds of wood, ensheathing one another about a common centre, which is occupied by a canal of pith, the whole being covered by the bark on the outside of the stem. A longitudinal section, however, shows that the stem is composed of a number of superposed and hollow elongated cones, the older ones forming a foundation for the new ones then forming and of succeeding years. The conical growth results from the conical formation of the first shoots, and is the foundation of the subsequent annual additions of wood and bark, for as these are deposited in strata parallel with the first year's wood and bark the conical form of the later layers is necessarily maintained. Growth in thickness and length is therefore the result of the same vegetative cause—the formation each year of a fresh conical layer, which extends from the bottom to the top of the tree. It is therefore evident that between the dimensions of length and breadth the branches are more cylindrical the longer they are, and more conical in proportion as they are shorter.

As conclusive examples of well-marked conical growth, those extremely short shoots termed thorns may be mentioned—the Blackthorn, for instance. That thorns are simply abortive branches is at once proved by the wild Plum tree, for in this tree, when transplanted and cultivated, the thorns soon develop into branches. The Willow, on the contrary, is an instance where the branches tend to a more cylindrical form. In consequence of this the branches of it are longer and very pendulous, their water-like curvature being extremely graceful, and as they wave backwards and forwards in the wind the tree presents a very picturesque appearance. All the Coniferæ are naturally conical-growing trees, and this is even apparent in their appearance. The Juniper, Red Cedar, Spruce Firs, Pine, and others, when seen even in the distance, clearly reveal by their outlines their conical growth.

This conical form is generally the original form of all trees in their early life. At first growth takes place in the direction of the main stem, and that of the branches is restricted; but after some years the stem grows to its greatest height, and then the growth is diverted to the branches, which then lose their conical outline, and spreading out around form a dome-shaped or hemispherical top or crown. This is particularly observable in the Horse Chestnut, the Lime, and the Elm, which by reason of this upper development impart a fine appearance to a park, in addition to the further recommendation of affording a perfect shade around their base. In the Coniferæ this development does not take place, for the tree stops at the first stage, and therefore ever retains its cone-like appearance. For this reason, as also too that on account of the simple character of their leaves and flowers, coniferous trees are considered as of a low type of organisation.

Trees undoubtedly derive their elaborate formative material from their leaves. This is apparent even in a single shoot, the figure of which depends on the manner in which the leaves are disposed on its surface; for as wood is formed by the leaves, when these are placed in regular order over every part of the circumference of the shoot, as in the Beech and Lime, the shoot is always necessarily cylindrical, for the woody matter proceeding from the leaves is thus distributed equally on all sides; but when the shoots are opposite or in pairs placed at right angles, as in the Maple, the descent of nourishing matter from them is necessarily limited to that portion of the stem immediately below, and consequently the young shoots and branches of such trees are square. All, however, depends upon the leaves. If the vital activity of these latter is too weak to form wood, if they remain crowded together at the top in clusters, there is no increase in breadth. Take shoots of the Horse Chestnut, for example. One shoot may be conical, the other cylindrical. The conical shoot is the growth of a year, the cylindrical perhaps of ten years, yet they are both about of a size. As their woody matter was derived from the leaves which clothed them, it follows that in the case of the ten-years shoot very little was supplied, and hence it is cylindrical, not conical, like the one year's growth. It follows that the breadth of the wood rings annually formed, and which we see in the transverse section of the stem, must also

correspond with the amount of entire leaf surface which is put forth into the atmosphere during the vegetative season.

To prove this we need only select branches the leaves of whose side shoots are annually put forth as leaf clusters, and which, therefore, exhibit but a minimum of development, and consequently exercise the least possible physiological influence on the branch, and where powerful growths are suddenly succeeded by growths greatly retarded. It is often seen that the three inner rings or woody layers formed by the leaves of the first three-years growth are much broader than the four outer rings, the leaf deposits of the next four years.

These evidences and others conclusively demonstrate that the breadth of the wood rings is determined, not by the activity of the leaves of the terminal shoot of the main stem, but that the leaves

FIG. 27.—IRIS HISTRIOIDES. (See page 112.)

of the side shoots, or of the whole system of shoots, co-operate. Therefore the leafage of each year forms a common source whence is derived not only the nutriment forming the new layer of each branch or system of shoots, but of the main stem—the support of all. The leaves are therefore indubitably the source of the elaborately formative material which they furnish to the shoots, from the shoots to the branchlets, and from these latter to the branches, whose ultimate union forms the main stem of the tree, just as many little rivulets, with their tributary streams, furnish, when united, a river, and eventually a sea.

Thus in the course of years solid and enduring vegetable monuments are reared, nothing but air and earth, yet woven by magic chemistry as it were from these first elements which outlive generations of mankind. Nature builds on the conical principle to insure stability, which is the inevitable result of her work.—WM. NORMAN BROWN.

THE BUNYARD CENTENARY SHOW.—We are pleased to hear, as a result of the show which was held at Maidstone last autumn, that 5 guineas each have been sent to the Gardeners' Royal Benevolent Institution, the Royal Gardeners' Orphan Fund, and the Maidstone Church Institute.

HINTS ON FORCING.

(Concluded from page 93.)

ROSES are at all times highly prized by flower lovers, and during the early spring months they are especially valued, for then they have a freshness and delicacy which fully compensates for the lack of size and substance the blooms show. Roses are, indeed, the floral queens of spring as well as of summertime. It is not a particularly difficult matter to obtain a few blooms throughout the winter, but flowers produced during December and January do not last long when cut owing to the sharp forcing the plants have to be subjected to, and for the same reason the crop per plant is not a large one. For these reasons the majority of cultivators do not begin forcing till the end of January or early in February. The plants then make rapid headway with the help of a little fire heat.

Tea Roses in pots were at one time left in the open air till wanted for forcing. The plan adopted was to plunge the pots over their rims in ashes early in the autumn, and on the appearance of severe weather straw or bracken was scattered over the shoots to afford some protection. A much better plan, however, is to place the plants under glass in October; any structure from which frost is excluded answers very well. With this treatment the wood is preserved in good condition, and the buds plump up ready for an early start. The pruning should be done some time during January, but it ought not to be a severe one. I have tried various practices, and have come to the conclusion that, except in a few instances, the best results are obtained when the knife is but sparingly used. I usually thin out such weak shoots as are not likely to flower, remove those branches which show signs of decay, and cut away the unripened points of very strong ones.

Some varieties of Teas send up strong suckers which grow to a great length. A good way to deal with these is to insert a few stakes round the sides of the pot, and coil such shoots around them. This, of course, changes their position from an upright to a horizontal one, and therefore somewhat checks the flow of sap, which has the effect of converting a "robber" into a useful member of the plant that produces it, as these strong shoots when so treated often eventually bear very fine blooms.

After the pruning is completed it is a good plan to syringe the plants with a solution of one of the many good insecticides now in commerce. The surface soil ought then to be removed, and a top-dressing given. A suitable compost for this purpose is one formed of good fibrous loam, inclined to be heavy rather than light, with a tenth of bonemeal added. Some cultivators pot at this stage any plants that are in comparatively small pots. I do not favour the practice, because I find with so many good artificial manures in the market it is an easy matter to feed liberally enough to enable the plants, without undue strain, to perfect a crop of flowers; by that time the roots are active, and the plant in the right condition for potting. With all Roses in pots I like to do the potting when they are in the open air during the summer months.

When the plants have been top-dressed a good method of procedure is to place half the number in a forcing house or vinery where a night temperature of from 55° to 60° is maintained, with a rise of 10° during the day, the other half being transferred to a cool greenhouse. By these means a good succession of flowers is maintained. The plants in heat will require copious syringings occasionally when the weather is bright, and fumigating whenever green aphides make their appearance. As soon as the growths are about an inch in length the weaker ones should be removed, as such never produce creditable flowers, and are therefore not wanted.

When pruning Hybrid Perpetuals totally different tactics must be followed, as in their case a free use of the knife is essential to success. Old and enfeebled shoots should first be cut away, weak side shoots removed, and the remainder shortened back to from one to three eyes of their base—i.e., the point from which they started last year, the strongest of course being allowed to retain the maximum number of eyes. When blanks occur through the removal of old shoots, young ones near may be left 9 inches in length to fill up the vacancy. Regular attention to such matters will result in shapely well-balanced plants, which when in flower have a much better appearance than ill-shaped ones, and are moreover likely to produce a greater percentage of fine blooms.

As soon as the flower buds are visible feeding becomes an important detail of culture. Liquid manure obtained from cesspools into which the drainage from stables and cowsheds is conducted is excellent for the purpose, if given in a greatly diluted state, about the colour of brown brandy. If this is applied two or three times weekly, and a dose of soot water given as well, the plants will be kept in good health. Artificial manure, if applied to the surface of the soil when the flower buds are swelling, is also a practice productive of fine results; indeed, where there is any difficulty in obtaining natural liquid manure, the artificial fertilisers may be depended upon entirely. The following varieties are some of the best for growing in pots.

TEA-SCENTED.—Adam, Anna Ollivier, Catherine Mermet, Comtesse de Nadaillac, Grace Darling, Hon. Edith Gifford, Homère, Isabella Sprunt, Madame Lambert, Madame de Watteville, Ma Capucine, Niphetos, Perle de Lyon, Safrano, The Bride, and Madame Falcot.

HYBRID PERPETUALS.—Beauty of Waltham, Fisher Holmes, Général Jacqueminot, John Hopper, La France, Mrs. J. Laing, Pride of Waltham, Marie Verdier, and Marie Baumann.—PLANTSMAN.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL, FEBRUARY 9TH.

THE meeting of the various Committees at the Drill Hall on the above date was large both as regards attendance and the number of exhibits. The display was bright, varied, and extremely interesting, each division—Fruit, Floral, and Orchid—being well represented.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, and Messrs. T. F. Rivers, G. Banyard, J. Cheal, J. H. Veitch, A. F. Barron, T. J. Saltmarsh, G. W. Cummins, A. H. Pearson, T. Fife, G. Norman, J. Smith, J. Willard, H. Balderson, F. Q. Lane, G. Sage, G. Reynolds, W. Bates, T. Farr, C. Herrin, W. Pope, A. Dean, and J. Wright.

As will be seen, there was a large attendance of members; but the products submitted for examination were limited.

Major Thornhill, Stanton Hall, Bakewell (Mr. G. Harvey, gardener), sent a plate of very fine Lemons, grown on the back wall of a house. A cultural commendation was unanimously awarded.

Messrs. Rivers & Son sent fine specimens of an Apple named *Carmen*—a flattish striped Apple, especially near the base; also fruits of *Prince Edward Apple*, soft and sweet, juicy, and pleasant; in appearance intermediate between Cox's Pomona and Cellini (award of merit). Messrs. Rivers also sent specimens of St. Martin's Apple. An award of merit was granted for this variety in the autumn, and the dark conical fruits were still in good condition.

Messrs. Rivers & Son had a very good table of fruit, consisting of thirty dishes of Apples and Oranges, and a silver Knightian medal was unanimously awarded.

Messrs. J. Cheal & Sons arranged sixty dishes of Apples and Pears, several very fine, and the exhibit highly creditable. A silver-gilt medal was awarded without a dissentient vote.

VEITCHIAN PRIZES FOR DESSERT FRUIT.—*Pears*.—First, R. Leigh, Esq. (gardener, Mr. Woodward) with *Passe Crasanne*; second, Mr. Owen Thomas, with *Ne Plus Meuris*. *Apples*.—First, Mr. W. H. Divers, Belvoir Castle, with *Blenheim Orange*; second, Mr. James Hudson, Gunnersbury, with *Scarlet Nonpareil*.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, C. T. Drury, R. Dean, J. H. Fitt, R. Owen, G. Stevens, J. F. McLeod, R. B. Lowe, C. J. Salter, J. Jennings, H. J. Jones, H. J. Cutbush, J. Peed, C. Jeffries, R. M. Hogg, W. Bain, J. D. Pawle, C. E. Pearson, C. E. Shea, C. Blick, H. Turner, G. Paul, J. W. Barr, E. Beckett, J. Fraser, and J. Laing.

Miscellaneous flowering and foliage plants in excellent condition and considerable variety came from Messrs. J. Peed & Sons, Norwood Road. Amongst them were Roman Hyacinths, Lily of the Valley, Cyclamens, Begonias, Prunus, Crotons, and Palms. The stand arranged by Messrs. J. Laing & Sons, Forest Hill, was largely composed of Palms, Ferns, Dracanas, and Isolepis, the whole making a good display. Mr. T. S. Ware, Tottenham, staged hardy bulbous flowers. Sprays of Lily of the Valley, arranged with their own foliage, came from Messrs. Young and Co., Stevenage.

A collection of hardy forced shrubs was exhibited by Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, which demonstrated the utility of this class of plants. Specimens of *Staphylea colchica* were carrying hundreds of flowers, while the branches of double white *Prunus* were wreathed with blooms. The group was edged with Roman Hyacinths and Narcissi, Lily of the Valley, Tulips, and Ferns. Mr. J. Willard, Holly Lodge, Highgate, sent six immense plants of *Begonia Gloire de Sceaux*, in which beauty had partially given way to coarseness.

S. Parnell, Esq., Woodlands, Streatham, sent a small group of Narcissi in variety. Plants of *Cyclamens* were exhibited by Messrs. H. Low and Co., Clapton. Mr. Chas. Turner, Slough, staged finely flowered *Cyclamens*. The colours were varied and good. Hardy flowers, including Scillas, Narcissi, Snowdrops, *Iris histrioides* (fig. 27, page 111), were shown by Messrs. Barr & Son, King Street, Covent Garden. Messrs. Cannell and Sons, Swanley, sent a magnificent collection of *Primulas*, comprising *pyramidalis rotundiflora alba*, *Mary George*, *Eynsford White*, *Future Queen*, *Eynsford Red*, *Swanley Blue*, *White Perfection*, *Glowworm*, *White Swan*, *Swanley Giant*, *Cannell's White*, *Cannell's Pink*, and many others. Messrs. B. S. Williams & Son, Upper Holloway, staged plants of *Azalea mollis* in variety.

Messrs. J. Veitch & Sons, Ltd., sent specimens of *Rhododendron hybrids*, *Rhodora canadensis*, and *Spiraea confusa*.

ORCHID COMMITTEE.—Present: S. Courtauld, Esq. (in the chair); with Messrs. De B. Crawshaw, J. O'Brien, H. M. Pollett, H. Ballantine, N. C. Cookson, E. Ashworth, J. T. Gabriel, H. Williams, F. J. Thorne, H. J. Chapman, W. H. Young, T. W. Bond, C. Winn, J. Douglas, J. Jacques, E. Hill, J. G. Fowler, and T. B. Haywood.

Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, staged a superb exhibit of Orchids. These were *Laelio-Cattleya Pallas*, *Cypripedium Harrisianum superbum* Oreson, *Selligerum* Mrs. Canham and *Euryades*, *Cœlogyne cristata*, *Denrobium euosmum roseum*, *euosmum virginale*, *Cordelia flavescens* and *Domini*, with many others.

Messrs. F. Sander & Co., St. Albans, also sent Orchids, in which *Cattleyas*, *Cypripediums*, *Lycaste*, and *Odontoglossums* were noticeable. Messrs. H. Low & Co.'s exhibit was composed mainly of *Dendrobiums*, and Messrs. B. S. Williams & Son's of *Cypripediums*. Mr. W. H. Young, Orchid grower to Sir F. Wigan, East Sheen, sent flowers of *Phalaenopsis*.

CERTIFICATES AND AWARDS OF MERIT.

Cattleya Trianae eximium (L. Linden).—A superb form. The large sepals are very delicate rose, the narrow petals being of the same hue. The lip is a grand feature: The outer portion is rich crimson, the throat being yellow on the lower portion and soft rose on the upper, this shade extending to the fimbriated margin (award of merit).

Cattleya Trianae Imperator (L. Linden).—The sepals and petals of this variety are rose. The lip is rich velvety maroon (award of merit).

Iris Bakeriana (R. Wallace & Co.).—With the exception of the lip the whole of this flower is pale blue. The fall is white with blue spots, the extremity being rich velvety deep indigo blue (first-class certificate).

Lælio-Cattleya Violetta (J. Veitch & Sons, Limited).—Pure rose is the colour of the petals and sepals of this hybrid. The lip is crimson with white fimbriated edges (award of merit).

Phalenopsis Hebe (J. Veitch & Sons, Limited).—This is a hybrid, resulting from a cross between *P. rosea* and *P. Sanderiana*. The sepals and petals are white, flushed rose, and the lip rose, shading pale brown at the base (award of merit).

Violet Amiral Avellon (T. Cripps & Son).—Deliciously fragrant is this single Violet (award of merit).

ANNUAL GENERAL MEETING.

ON Tuesday last the annual general meeting of the Royal Horticultural Society was held at the Offices, 117, Victoria Street, S.W. The chair was taken by Sir Trevor Lawrence, Bart., the popular President of the Society. The meeting was an excellent one, upwards of eighty members being present. At three o'clock precisely the Chairman called upon the Secretary to read the minutes of the last annual general meeting, these being afterwards signed as correct. Many new Fellows were then elected, and Messrs. J. Cheal and H. Turner were appointed scrutineers of the ballot for the election of three members to the Council in place of Sir Alexander J. Arbuthnot, K.C.S.I., H. J. Pearson, Esq., and G. Bunyard, Esq., who, in accordance with the Charter, had to retire. Sir Trevor spoke in high terms of the services that had been rendered by these gentlemen both to the Society and to horticulture. Messrs. Norman C. Cookson, William Marshall, and Harry J. Veitch were elected to the Council in place of those retiring.

The report and balance-sheet published several days ago were taken as read, a copy having been sent to all Fellows of the Society. In moving the adoption of both of these, Sir Trevor was very happy and *apropos*. Each salient point was brought lucidly forward. He said he was glad to be convinced that the year had been one of useful work smoothly and happily done, and considered that the Council's verdict of satisfactory was fully justified. The several alterations that have been made at Chiswick during the year were adverted to, and attention was called to the fact that it was just ten years since it was found imperative to quit South Kensington. Mr. Wright's services at Chiswick were eulogised in no stinted terms, the Chairman saying that the Superintendent's skill and sound knowledge were already clearly perceptible.

Continuing, the new departure of "painting all Orchids that received an award of merit or a certificate" was referred to, and thanks were again given to fruit growers who had sent trees to Chiswick, and to the many readers of excellent papers. Financially everything was deemed satisfactory, and the membership was annually increasing. Several other things were noted, Sir Trevor concluding with a glowing tribute to that most excellent of Secretaries, the Rev. W. Wilks. The expressions relative to Mr. Wilks were received with acclamation, as were others referring to Mr. J. Weathers, the Assistant Secretary. Professor Michael Foster seconded the adoption of the report. His remarks were terse and interesting, and were hailed with much pleasure by the members. On the proposition being put to the meeting it was carried unanimously.

Mr. G. Bunyard proposed a vote of thanks to Sir Trevor Lawrence for his admirable services. This, after being seconded by Dr. M. T. Masters, was, it is needless to say, passed with full accord. The meeting then closed.

REPORT OF THE COUNCIL FOR 1896-97.

THE Council are glad to be able to report the conclusion of a full and satisfactory year's work.

Financially, the balance in hand is not as large as it was last year, but this is more than accounted for by the extraordinary expenditure which the Council felt able to undertake at Chiswick, the whole of which has been defrayed out of income. The conservatory at the entrance to the gardens, which had for so many years required repair, has been entirely removed, and replaced by a building in every respect worthy of the Society; and the two old greenhouses, Nos. 1 and 2, which had been an eyesore to the gardens by reason of their ruinous condition for almost a generation, have been remodelled and rebuilt. The total of this extraordinary expenditure is over £500.

Under the head of ordinary expenditure at Chiswick £1870 has been spent on the general work and repairs and keeping up of the gardens. Amongst other work House No. 17 has been practically rebuilt, Nos. 15 and 6 have been very thoroughly repaired; the young men's bothies have also been put in good order and made more comfortable. The receipts by sale of surplus produce amount to £344, making the net ordinary cost of the gardens £1526.

The Council have every reason to congratulate themselves and the Society upon the selection which they made to fill the office of Garden Superintendent.

At Westminster nineteen Fruit and Floral meetings have been held in the Drill Hall, James Street, Victoria Street, and six Committee meetings have been held at Chiswick, besides the larger shows in the

Temple Gardens on May 19th, 20th, and 21st and at the Crystal Palace on October 1st, 2nd, and 3rd. Lectures have been delivered at fifteen of the meetings, exclusive of those given at the Crystal Palace. The number of awards granted by the Council, on the recommendation of the various Committees, has been as follows:—

AWARD.	At Provincial Shows.	On the Recommendation of the					Total.
		Scientific Committee.	Fruit Committee.	Floral Committee.	Orchid Committee.	Narcissus Committee.

Commended ...	3	—	—	—	—	—	3
Total ...	75	1	102	463	303	4	948

The Council must again express their opinion that there still appears to be a tendency to multiply unduly the awards recommended, and they earnestly request the several Committees to consider seriously whether there is not a real danger of impairing the value of these distinctions by such increase of their number, and whether it would not be possible, as well as politic, to be somewhat less generous in the recommendation of awards during the ensuing year. This is a question which the Council cannot but regard with solicitude, and they hope that every member of the Committees will consider that he has a real individual responsibility for the welfare of the Society in this matter.

The work of the Committees has of late increased so considerably that the delay of communication between the Council and the Committees has on several occasions caused great inconvenience. The Council, therefore, think it well to revert to an old rule of the Society, that the Chairmen of the principal Committees shall in future be chosen from among the members of Council.

At the unanimous request of the Orchid Committee, and on certain members of it undertaking to pay a third of the expense, the Council have arranged to have paintings made of all the flowers certificated by this Committee. Exhibitors must, therefore, distinctly understand that in submitting their flowers in future to the Committee, they thereby tacitly consent to their being painted should they obtain any award, and must hold themselves ready to give all reasonable facility to the Society's artist to do so. The Orchid Committee desire to have these paintings as an accurate record of the characters and peculiarities of the plants to which awards are made, finding it practically impossible for their members to bear in mind the details of numerous flowers often seen but once.

The Council desire to draw the attention of all Fellows of the Society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in submitting instances of diseases of or injuries to plants, caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the best advice on all such subjects, either in respect to the prevention or cure of disease. The Committee is also glad to receive specimens of malformation or other subjects of horticultural or botanical interest.

The Council wish to express their thanks to the Director of the Royal Gardens, Kew, for allowing them to consult Mr. Massee, F.L.S., on the fungoid diseases, &c., brought before the Scientific Committee, and to that gentleman for his readiness in giving them the advantage of his knowledge and advice.

The Society's great show, held (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as successful as ever, and it is a matter of satisfaction to the Council to find that this meeting is now universally acknowledged to be the leading horticultural exhibition of this country. The best thanks of the Society are due to all who kindly brought their plants for exhibition, or otherwise contributed to the success of this show.

The exhibition of British grown fruit, held by the Society at the Crystal Palace on October 1st, 2nd, and 3rd, was, considering the season, eminently satisfactory. Full particulars will be found in vol. xx., part 2, of the Journal, issued in December.

As an object lesson in British fruit cultivation this annual show stands unrivalled, and is of national importance. The Council invite Fellows and their friends to support it, for it cannot be too widely known that the continuance of the show year by year is absolutely dependent on at least £100 being raised by subscriptions each year towards the prize fund. The show involves the Council in a very

large expenditure without the possibility of any return. They have therefore established the rule that they will not continue it unless sufficient interest in it is taken by Fellows and their friends to raise £100 towards the Prize Fund. Subscriptions for this purpose should be sent at once to the Secretary, 117, Victoria Street, Westminster, and if the list prove satisfactory the schedule will be issued in April, and the show held on September 30th and October 1st and 2nd, 1897. The list of subscribers for 1896 will be found on page 129 of vol. xx., part 2, of the Society's Journal.

Deputations were sent by the Council at the invitation of the local authorities to attend the great horticultural gatherings at York in June, and at Chester in August, 1896. Full particulars of these visits will be found in the Society's Journal, vol. xx., part 1, p. xxvii., and vol. xx., part 2, p. cxxx. The Council cannot, however, refrain from taking this opportunity of congratulating York and Chester on the admirable displays of horticultural skill and enterprise made at their respective fêtes and galas, and of recording the very great pleasure which these visits gave them, and their appreciation of the great courtesy and hospitality with which they were received in both cities.

The Journal of the Society has been continued so as to enable Fellows at a distance to enter more fully into and reap the benefits of the study and work of those actively engaged at head-quarters. Vol. xix., part 3, and parts 1 and 2 of vol. xx., were issued during the year, and vol. xx., part 3, is now almost ready for issue.

In January, 1893, the Council published a list of all the plants, flowers, fruits, and vegetables certificated from the year 1859 to 1892. A supplement is now ready, bringing the list down to December, 1896. Each part is issued at the price of 1s., but the two together may be obtained for 1s. 6d., at the Society's Office.

An examination in the principles and practice of horticulture was held on May 1st, concurrently in different parts of the United Kingdom, a centre being established wherever a magistrate, or clergyman, or schoolmaster, or other responsible person accustomed to examinations would consent to superintend one on the Society's behalf, and in accordance with the rules laid down for its conduct. No limit as to the age, position, or previous training of the candidates was imposed, and the Examination was open to both sexes. 152 candidates presented themselves for examination. The names and addresses of those who succeeded in satisfying the examiners, together with the number of marks assigned to each, will be found in the Society's Journal, vol. xx., part 1, 1896, page 58.

It is proposed to hold a similar examination in 1897, but at the request of those most nearly concerned the date has been altered to Tuesday, April 6th, so as not to clash with the examinations held at the beginning of May by the Science and Art Department. Candidates wishing to sit for the Examination should make application during February to the Secretary, R.H.S. Office, 117, Victoria Street, Westminster.

The Council have heard with much pleasure that N. N. Sherwood, Esq., Master of the Worshipful Company of Gardeners, has most kindly offered, in connection with the Society's 1897 Examination, a Scholarship of £25 a year for two years; full particulars of which will be found in the Society's arrangements for 1897, lately issued to all Fellows. Another similar Scholarship has been promised for 1898, by G. W. Burrows, Esq., a member of the Court of the same Worshipful Company.

Acting in conjunction with the Lindley Trustees, the Council have devoted considerable attention to the library. All serial publications have been kept up to date, a large number of valuable volumes have been bound, and the following new books, amongst others, added to the library—viz., "The Student's Handbook of British Mosses," "Les Vignes Americaines," "Useful Plants of Japan," "Orchids of South Africa," Scott's "Flowerless Plants," &c., &c.

A sum of £129 has been received for the catalogue fund, which was started in 1894, and the proof sheets of the catalogue are now in the hands of the printer.

The hearty thanks of the Society are due to all the members of the standing Committees—viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchid, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments.

The best thanks of the Society are also due to all those who, either at home or abroad, have so kindly presented books to the library or plants or seeds to the gardens. A list of the donors has been prepared, and will be found in the Society's Journal, vol. xx., part 3, 1897, now almost ready for issue. Where so many have been generous it almost appears invidious to mention any by name, yet the Council think it only their duty on behalf of the Fellows to publicly thank the principal donors, amongst whom have been Messrs. George Bunyard & Co. of Maidstone, Mr. John Fraser of Woodford, Messrs. Lee & Son of Hammersmith, Messrs. Paul & Son of Chesham, Messrs. J. R. Pearson & Sons of Chilwell, Messrs. T. Rivers & Son of Sawbridgeworth, and Messrs. James Veitch & Sons of Chelsea.

The Council wish to express, in their own name and in that of the Fellows of the Society, their great indebtedness to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the fortnightly meetings in the Drill Hall. They are glad to find by the increased and increasing number of visitors that the Society's fortnightly meetings are at last becoming appreciated by the Fellows and public in general. In their judgment these shows, which take place at short intervals throughout the year, furnish horticultural displays and teach horticultural lessons which cannot be obtained elsewhere in the kingdom.

The papers read at these meetings, which have been or will shortly be published in the Journal, are as follows:—March 10th—"Melons," by Mr. J. Barkham. March 24th—"Saladings," by Mr. W. Iggulden. April 21st—"Pine Apples," by Mr. H. W. Ward. May 5th—"Species and Varieties of Tulips," by Mr. J. G. Baker, F.R.S. June 9th—"The Movements of Plants," by the Rev. Prof. George Henslow, M.A. June 23rd—"Gardeners Past, Present, and Future," by Mr. S. Heaton. July 14th—"New Roses," by the Rev. H. J. Pemberton, M.A. July 28th—"Cacti," by Mr. E. H. Chapman. August 11th—"Fern Generation," by Mr. C. T. Druery, F.L.S. August 25th—"Forcing Lilies of the Valley," by Mr. T. Jannoch. September 8th—"Gladioli," by Mr. J. Burrell. October 1st—"Fruit Growing from a Food Point of View," by Mr. E. J. Baillie, F.L.S. October 2nd—"Cider and Perry Industry," by Mr. C. W. Radcliffe Cooke, M.P. October 3rd—"Gathering, Storing, and Use of Apples and Pears," by Mr. J. Watkins. October 13th—"Hardy Summer Flowers," by Mr. E. Burrell. October 27—"Chrysanthemums," by Mr. W. H. Lees. November 10th—"Seed Growing," by Mr. R. Fife. November 24th—Floral demonstration by the Rev. Prof. George Henslow, M.A.

The Council have the sad duty of recording the death of twenty-two Fellows during the year, and among them they regret to find the names of Baron Sir Ferdinand Von Mueller, one of the most staunch and energetic supporters of the Society in Australia; Dr. Trimen, Bruce Findlay, Richard Bloxam, Henry Seeborn, T. A. Gledstanes, Anthony Waterer, the Earl of Darnley, Sir Joseph Prestwich, Lord Savile, Robert Warner, Sir Julian Goldsmid, George Prince, and Marmaduke Lawson.

The following table will show the Society's progress in regard to numerical strength during the past year:—

DEATHS IN 1896.				FELLOWS ELECTED 1896.

A scheme for the affiliation of local Horticultural Societies was put forward in 1890, and eighty-three local societies have availed themselves of it. The Council express the hope that Fellows will promote the affiliation of local Horticultural and Cottage Garden Societies in their own immediate neighbourhood.

Subjoined is the usual Revenue and Expenditure Account, with the balance-sheet for the year ending December 31st, 1896.

The programme for the ensuing year will be found in the arrangements for the year 1897, lately issued to all Fellows.

At the request of some of the Fellows, the Council have arranged to send a reminder of every show (in the week preceding it) to any Fellow who will send to the R.H.S. Office, 117, Victoria Street, Westminster, twenty-two halfpenny post-cards, fully addressed to himself, or to whomsoever he wishes the reminder sent.

The Council recommend that the salaries of the principal officers of the Society—the Secretary, the Assistant Secretary, the Superintendent, and the Assistant Superintendent should continue as heretofore.

The Council have had before them various proposals for celebrating the attainment by Her Most Gracious Majesty the Queen, Patron of the Society, of the longest reign in English history. Some of these proposals were for one reason or another found to be impracticable, others were found to involve a far larger expenditure of money than the Society can command or could reasonably hope in so short a period to collect. They have therefore after most careful consideration decided, with Her Majesty's gracious permission, (i) to strike a special medal or medallion, to be called the Victoria Medal of Horticulture and to be awarded *honoris causa* in the domain of horticulture. They will also (ii.) join in the celebration of the event which is to take place at the great show to be held at Shrewsbury in August, to which they have received a very cordial invitation.

The proposal to strike a Victoria Medal of Honour has been submitted to Her Majesty, who whilst refraining in this as in all other cases from expressing any personal opinion on the proposed method of commemorating the sixtieth year of her reign, graciously adds that she "has no possible objection to raise" either to the proposal itself or to the name to be given to the Medal.

The Council in closing their report desire most respectfully to tender to Her Majesty the most sincere and thankful congratulations on the approaching completion of the sixtieth year of her beneficent and auspicious reign, and they are confident that every Fellow of the Society will join with them in saying "God save the Queen."

ANNUAL REVENUE AND EXPENDITURE ACCOUNT FOR THE YEAR ENDING 31st DECEMBER, 1896.

POTATO COOKING.

It will be remembered by the readers of the *Journal of Horticulture* that a report appeared on the tercentenary of the Potato in Dublin on December 7th, page 587. In it extracts from the speeches delivered by His Excellency the Lord Lieutenant was reported, and a paragraph at the end of the report struck me very forcibly, and appeared most appropriate to the occasion.

If a small amount of space can be found for a repetition of the paragraph alluded to it will serve the purpose of my letter. His Excellency is reported to have said, "You may grow your Potato, and you may bring it in triumph into your house; but if you don't know how to cook it it is impossible to appreciate it at its full value. I rather wish that the gentlemen who have promoted this exhibition had one section in which to show us how to cook our Potatoes. Englishmen are absolutely hopeless in this line of business, and I can only say for myself—I say so with all due respect to Lady Cadogan—that I never see a Potato properly cooked in my own house. Since I have been in Ireland a large number of my friends have broken bread in my house, but it is not too much to say that not one of them could have broken the Potatoes there. Mine are waxy, hard, and thoroughly indigestible, and if any lady would kindly allow my cook to come down and see how Potatoes are cooked in Ireland my presence here will have a result which will be a blessing for the remainder of my life."

After such an exposure of incompetency as this I thought some of our sensitive cooks would have been stimulated into some sort of defensiveness on their cooking capabilities; but to my surprise no reference has been made to the subject. I am tempted to pen this note through the receipt of a trade pamphlet, entitled "Allotment Holders' Guide, Seed and Plant List." In it is much valuable information, but when the author gives his advice how to treat Potatoes before cooking I beg to differ entirely from him. He says:—"After Christmas I have all my Potatoes peeled overnight and laid in cold water until wanted to cook. I beg all to try this; they will find it greatly improves them."

What has our Irish friend to say to such advice as this? Would not a few short notes in the *Journal* from an Irish source be very acceptable and probably of some benefit to many of its readers? If our Potato spoilers were to see, as I have done, the beautiful, tempting, floury balls turned out by the Irish, strangers to the customs of these people would not be so surprised when told that many a family in that part of Her Majesty's kingdom make many a meal on nothing else. A finer, stronger, and healthier race of people are not to be found in the United Kingdom. But reverse it. Put before those people and compel them to eat those indigestible things called by some English cooks Potatoes. I fear they would soon become subjects of weakness and debility. —J. E.

WEATHER IN LONDON.—The weather in London during the past week has been characterised by many changes. On Thursday night of last week rain fell heavily, as it did on Friday. Saturday and Sunday brought slight night frosts, but on Monday it was wet again. Tuesday and Wednesday were very dull, though little rain fell on either day.

— WEATHER IN THE NORTH.—The weather for a week has been very unpleasant. The frost gave way on the 3rd inst., and was followed for several days by a cold undecided thaw with easterly wind. On Saturday afternoon the wind set into the west, and the snow rapidly disappeared. The morning of Tuesday was inclined to be showery with a brisk breeze from the west.—B. D., *S. Perthshire*.

— DEATH OF MRS. FOSTER-MELLIAR.—It is with extreme regret, in which numbers of rosarians and others will share, that we have to record the death of the beloved wife of the Rev. A. Foster-Melliar, which occurred at Sproughton Rectory, near Ipswich, on Thursday morning last. The deceased lady had been seriously ill for some time, but under the best procurable medical skill and attention it was hoped she would survive. We are informed, however, that the combination of diphtheria, pneumonia, and pleurisy so weakened her, that after the fever part of the illness she had not strength to rally. Mrs. Foster-Melliar was a most charming lady, taken away in the prime of life. Her loss will be deeply mourned by a sorrowing family, and unbounded sympathy extended to the Rector in his great bereavement.

— SHROPSHIRE HORTICULTURAL SOCIETY.—The annual meeting of the members of this Society was held on Monday last, February 8th, under the presidency of the Mayor of Shrewsbury in the absence of Sir W. O. Corbet, Bart., the President. The accounts submitted showed that the receipts for the year were nearly £4300, of which sum over £3000 was for admission by ticket or payment at the entrance alone. The subscriptions amounted to £445, other receipts making up the amount named. The expenses of the floral fête were about £3100, and the gross profit on the fête was £1200. After deducting the expenses of the spring show and sundry sums voted the net profit of the year was £1015, which will be expended as has been announced in the erection of a bronze statue to Charles Darwin. The cash prizes awarded were considerably over £800. Lord Kenyon was elected President for 1897. The commemorative show to be held in August next in connection with the R.H.S. was referred to in the report, and no expense will be spared to make this show one of the finest in England. Hearty votes of thanks were given to the Hon. Secretaries, Messrs. Adnitt and Naunton, and the other officials of the Society.

— HORTICULTURAL CLUB.—The twenty-second annual dinner of the members and friends of this Club was held at the Hotel Windsor, Victoria Street, Westminster, on Tuesday evening last. The highly respected President of the Club, Sir John D. T. Llewelyn, Bart., M.P., though engaged in the House of Commons during the dinner, hastened away immediately after the division on a subject with which he was closely identified in time to conduct the after proceedings, which he did with consummate ability and tact. The tables were beautifully, in fact almost too heavily, decorated with plants and flowers by Messrs. Veitch and Sons, Limited, while fruit was abundantly supplied by Messrs. Assbee, Monro, Rivers, Bunyard, and others. Mr. George Bunyard also contributed substantially to the musical part of the proceedings; his son, Mr. Ashdown Bunyard, ably presiding at the pianoforte, and a "Band of Brothers," the Messrs. Lamb, being brought from Maidstone—a quartette of vocalists who gave great satisfaction. Mr. Harry Turner also demonstrated his mastery over the concertina in the rendering of charming solos. In addition to the loyal toasts, were given the "Horticultural Club," the "Royal Horticultural Society," the "Visitors," and the "Chairman." Among the guests were the Clerks to the Ancient City Guilds, the Gardeners' and the Fruiterers' Companies, Mr. J. Wright, *Journal of Horticulture*, and Mr. S. T. Wright, Chiswick. The principal speakers were the Chairman, Secretary, Mr. George Paul, Mr. C. E. Shea, and Mr. George Bunyard, and a very pleasant evening was spent by all who were present on the enjoyable occasion.

— GARDENING APPOINTMENTS.—Mr. Mark Woollard, for seven years foreman at Thoresby, has been appointed gardener to — Gill, Esq., Woodheys Hall, Ashton-upon-Mersey. Mr. H. T. Martin, for nearly four years foreman with Mr. E. Beckett, Aldenham House Gardens, has been appointed gardener to the Right Hon. Lord Leigh, Stoneleigh Abbey, Kenilworth.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Readers will recollect our calling attention (page 46) to the Victorian Era Fund, promulgated for the temporary assistance of candidates awaiting election. We are glad to announce that in aid of this excellent fund a performance of the well-known comedy-opera "Dorothy" will be given by the Westminster Amateur Operatic and Dramatic Society at St. George's Hall, Langham Place, on Thursday, February 18th, 1897. Considering the object of the performance, it is to be hoped that the response will be hearty, and that the fund will benefit to a material extent. Tickets may be obtained from Mr. H. Morgan Veitch, 16, Clifford's Inn, E.C., who is Secretary for the performance.

— ROOTING CARNATION CUTTINGS.—The various methods of rooting Carnation cuttings were ably described by Mr. W. Bardney on page 73. Last summer I tried for the first time the "mossing dodge," which I saw described in the "Field" some time previously, and was surprised at how well it succeeded. A cut is made through a joint, as in the process of layering. A small piece of stone or cinder is placed in the cut to keep it open, and a piece of moss tied round it. The plants were kept syringed to keep the moss moist, and in three weeks the cuttings were fit to cut off and place in small pots, moss and all. This refers to Malmaisons. By this means shoots too short to layer can be rooted just as easily and safely as longer ones will by layering.—R. I.

— ISLE OF WIGHT HORTICULTURAL ASSOCIATION.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at the Guildhall, Newport, on Saturday last. Dr. Groves, B.A., J.P., presided over a large audience to hear a paper read by Mr. H. J. Jones of Ryecroft Nurseries, Lewisham, on the Chrysanthemum. Mr. Jones, in a lengthy, well written essay, dealt with the cultivation of "mums" from the taking of the cuttings to staging the blooms at exhibitions. At the close a collection was made in aid of the Gardeners' Benevolent and Orphan Funds, which amounted to £2 4s. Several new members were elected. The next lecture will be given by Mr. W. Lubbeck, F.R.H.S., Brooke House, I.W., on "Winter Vegetables."

— BALANCING ACCOUNTS.—When a few days since I rode by train along a great portion of the county of Surrey traversed by the river Wey, which finally empties into Father Thames, the parent, or at any rate the recipient just now of so many other flowing streams, and saw how for many miles and in all directions it had overflowed its banks, covering hundreds of acres of land with its flood, I could but realise that Nature had been not merely balancing accounts, but doing so with compound interest. Now there can be no doubt but that deficiencies of previous years have been made up, and all the rain that may fall, as probably much will fall during the present traditional fill-ditch month, will be largely surplusage. Like to a gorged stomach, the land not only cries "Hold, enough," but seems to reject what now falls of water, and thus every ditch, and streamlet, and river is more than full. It is rather more than two years since we had such heavy and continuous rains, but so far happily the present ones have not been followed by such disasters. Those floods, too, of the winter of 1894-95 were followed by intense frosts, such as we have to encounter about once only in a lifetime. It does not seem at all probable that frosts of any severe character will now follow, and indeed we hope it may not be so. Light porous soils are wet enough and the subsoils thoroughly saturated, whilst stiff clays are in a terribly sodden state. These specially need a dry time to enable them to part with their too abundant moisture ere baking March winds come. We may be certain now that trees, shrubs, or all deep-rooting things will not lack root moisture during the ensuing summer.—A. D.

— 113° IN THE SHADE.—The mail brings tidings of intense heat in New South Wales at Christmas time. In Sydney it was bad, but at Broken Hill, with 113° in the shade, it was unbearable. At Wilcannia a terrible dust storm prevailed; at Maitland very considerable damage was done to the Grape crops. The Vine in the sister colony, at Bendigo, is being harassed by the old enemy, phylloxera. On December 27th showers fell in Melbourne charged with a finely powdered substance of a reddish tinge, and the streets presented the appearance of having been stained with red.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 17th inst., at 7.30 P.M., the following papers will be read:—"Report on the Phenological Observations for 1896," by Edward Mawley, F.R.H.S., President; "Results of Observations on Haze and Transparency near Haslemere, Surrey," by the Hon. F. A. Rollo Russell, M.A., F.R.Met.Soc.

— **WEATHER AT DOWLAIS.**—The following is a summary of the weather here for the past month:—Rainfall, 2.68 inches; snow, 0.59; making a total fall of 3.27 inches. Maximum for rain, 0.74 on the 6th; and for snow, 0.20 on the 26th. Total amount of sunshine, 49 hours 40 minutes. There were fifteen sunless days. Temperature, mean maximum for month, 0.37°; ditto minimum, 0.27°; mean average for the month, 0.32°. The wind was in the N. and N.E. on twenty days. There were bitter winds for several days, and outdoor work was suspended for the whole of the month.—WM. MABBOTT, *Dowlais, South Wales*.

— **SUSSEX RAINFALL.**—The total rainfall at Abbot's Leigh, Haywards Heath, for the past month was 2.34 inches, being 0.21 inch above the average. The heaviest fall was 0.46 inch on the 8th; rain fell on fourteen days. The maximum temperature was 47° on the 7th and 10th, the minimum 22° on the 22nd and 24th. Mean maximum 39.05°; mean minimum 31.21°. Mean temperature 35.13°, which is 0.81° below the average. The frost and snow which came on the 23rd gave way on the 30th, and is now (February 1st) all gone, except where it was drifted.—R. I.

— **THE WEATHER LAST MONTH.**—January was cold, but severe frost only occurred on 23rd and 24th. The ground was covered with snow for the last fifteen days. The wind was in a northerly direction sixteen days. Total rainfall 1.44 inch, which fell on twenty-two days, the greatest daily fall being 0.32 inch on 7th. The total is 0.34 inch below the average for the month. Barometer (corrected and reduced) highest reading 30.544 inches on the 2nd at 9 A.M., lowest 29.340 inches 30th at 9 A.M. Temperature, highest in the shade 47° on 1st; lowest 22° on 23rd and 24th. Mean of daily maxima 37.29°; mean of daily minima 29.83°. Mean temperature of the month 33.56°. Lowest on the grass 17° on the 24th; highest in the sun, 92° on the 23rd. Mean of earth at 3 feet 39.90°. Total sunshine 49 hrs. 30 min. We had thirteen sunless days, seven of them in succession, 7th to 13th.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— **CARDIFF HORTICULTURAL SOCIETY.**—The annual general meeting of this Society was held on the 4th inst., under the presidency of Alderman W. J. Trounce, J.P. A large number attended, and it was resolved to hold the Show on August 11th and 12th. The past year was a most successful one, and a substantial balance is carried forward. The following are the officers:—President, The Mayor of Cardiff; Chairman, Mr. W. C. Peace; Vice-Chairman, Mr. A. E. Dixon; Secretary, Mr. H. Gillett, and an executive committee of nine members. The name of the Society was altered to the Cardiff and County Horticultural Society.

— **WORKSOP ROSE AND HORTICULTURAL SOCIETY.**—After the most strenuous efforts of a few ardent amateurs and gardeners, whose labours merited a much better public response than has been accorded, it has been determined to suspend the operations of this Society. The annual meeting of the Society was held at the Royal Hotel on Friday evening. Mr. H. V. Machin, J.P., the President, and an ardent supporter of the Society, occupied the chair, and there was also a good attendance of members. Seeing that the gate money at the last show was only £33 2s., and that there was only a balance of £13 2s. 1d. in the Treasurer's hands, the position of the Society was explained at some length by the Chairman and the Vice-President, and after considerable discussion it was decided on the motion of Mr. Alderman, seconded by Mr. Crasp, that it would be advisable to dissolve the Society. As to the balance in hand, it was proposed by Mr. Crasp, and seconded by Mr. Stewart, that the money be handed over to the Gardeners' Royal Benevolent Institution. An amendment was proposed by Mr. Cookman, and seconded by Mr. Ancock, that the balance be placed in the hands of Messrs. H. V. Machin, J. S. Whall, and G. Baxter, with power to hand the same or any part thereof to any horticultural society which may be established to their satisfaction in the district within three years, and that if no such society be established, the money at the end of that time be handed over to the Institution named. On a vote being taken the amendment was carried by eight to four. Votes of thanks were passed to the officers of the Society for their services during the past year, and on the motion of Mr. Whall, a similar compliment was paid to Mr. Machin for all his past efforts in connection with the Society.

— **MR. A. F. UPSTONE.**—We learn that Mr. A. F. Upstone, formerly with Messrs. Daniels Bros., Norwich, and James Veitch & Sons, Chelsea, has taken over the seed and florist business carried on for so many years by Messrs. Cobban & Son, Market Place, Rotherham.

— **NITON HORTICULTURAL SOCIETY.**—The annual meeting of the Niton Horticultural and Cottage Garden Society was held on Friday, February 5th. The balance-sheet showed £3 5s. in the hands of the Treasurer. A. V. Innes-Vine, Esq., was re-elected President, Mr. J. W. Creeth Treasurer, and Mr. W. Cotton Secretary. Special prizes are offered at the next show, to be held on August 18th, by Messrs. Sutton & Sons and Messrs. Toogood & Sons.

— **JANUARY WEATHER AT HODSOCK PRIORY, WORKSOP.**—Mean temperature, 33.9°. Maximum in the screen, 45.7°; minimum in the screen, 19.9°; minimum on the grass, 12°. Number of frosts in the shade, twenty-one; on the grass, twenty-five. Sunshine, 38.5 hours, or 16 per cent. of possible duration. Rainfall, 2.37 inches. Rain fell on twenty-three days. Maximum fall, 0.76° on the 7th. The first part wet; the rest of the month cold and wintry. Day temperature very low, but no severe frost at nights.—J. MALLENDER.

— **DEATH OF MR. H. BOSWELL.**—The death has occurred at Headington of Mr. Henry Boswell, of 50, Cornmarket Street, Oxford, the eminent bryologist. The deceased had not only studied the Mosses of Britain, but had an intimate acquaintance with a great number of foreign species, and his knowledge was utilised by many correspondents in different parts of the world. Mr. Boswell had named and described several new Mosses. He possessed a large collection, which it is hoped will be secured by the University. In recognition of his services to bryological science Oxford University conferred upon him in 1887 the honorary degree of Master of Arts.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—The annual tea and social gathering of the members and lady friends of this Society was held at the Colonnade Hotel recently, when nearly 100 persons were present. An excellent programme, consisting of vocal and instrumental music, was provided, with appropriate speeches delivered by Mr. W. B. Latham (the genial Chairman), Mr. Walter Jones (the Vice-Chairman), and various others. Much praise also was due to the energetic Hon. Secretary, Mr. John Hughes, for his painstaking arrangements. More than one member adverted to the beneficial influence of the Society in local gardening since its inauguration, eleven years ago, under the influential patronage of the late Sir Thomas Martineau. The Association continues to flourish, under the esteemed presidency of Mr. A. Winkler Wills, F.C.S.—W. G.

— **A "GRAND OLD MAN."**—The late Mr. Charles Jenner, brother of Sir William Jenner, the distinguished physician, to whom I incidentally alluded in a recent contribution as possessing the first plant of the Crimson Rambler Rose that came to this country, was a collector of statuary, and a great cultivator of alpine flowers. Now that his residence near Edinburgh has been sold, I hope that his exceptionally valuable alpine and herbaceous garden, containing many treasures of the most attractive kind, of which some years ago I wrote a description in a London journal, may not be permitted to fall into decay. Few places in Scotland possessed greater fascination for the lover of alpine flowers. I do not know if it was ever visited by your gifted correspondent, Mr. S. Arnott, to whom I feel certain that Mr. Jenner's unique collection would have been singularly interesting.—DAVID R. WILLAMSON.

— **THE LATE EARL OF KINNOULL.**—George, eleventh Earl of Kinnoull, died at Torquay, 31st January, 1897, and was interred at the family burying ground on 6th February. This popular nobleman was seventy years of age, and long held a distinguished position in the county of Perth. His Lordship was much esteemed by agriculturists, arboriculturists, and horticulturists, by reason of the great interest he took in them and encouragement he gave to these industries. The splendid policies of Dapplin give tangible proof of the love which the late Earl and Countess (who died two years ago) had for the adornment of the beautiful grounds around the Castle. By the picturesque drives, walks, and even the public highways many Coniferae are thriving admirably, and being in prominent positions are very effective. The able and courteous gardener and estate manager, Mr. Browning, is one of the best known and most respected of his class in the North. The floral display in the private chapel and at the graveyard was elaborate. Lord Hay of Kinfauns is successor to the titles and estates. It is believed that the good taste which has been manifested for generations of ancestors at Dupplin will not be lacking in the future at that princely seat.—M. TEMPLE, *Carron, N.B.*

LÆLIO-CATTLEYA NYSA SUPERBA.

WHEN *Lælio-Cattleya Nysa* was exhibited by Messrs. Jas. Veitch & Sons, Ltd, it attracted, by its distinct and charming beauty, a wonderful amount of attention amongst orchidists, and any varieties of the type are eagerly sought for. One of these, named L.-C. N. *superba*, when staged at the Drill Hall by the same firm on November 10th of last year, was promptly accorded a first-class certificate by the Orchid Committee of the Royal Horticultural Society. Such a recognition was thoroughly deserved, for in it the many excellent points of the type are intensified. Our woodcut (fig. 28) will convey to readers the form of the flower, while the colour of the sepals and petals is soft rose, and that of the superb lip rich velvety crimson with golden side lobes.

POTTING ORCHIDS—PSEUDO-BULBS DECAYING.

1, In potting Orchids that have not increased in size would it be preferable to clean away the old material and repot in the same sized pot or to let the old ball remain and increase the size of the pot. 2, Is there any remedy to prevent the entire decay of *Cattleya labiata* pseudo-bulbs when attacked with mildew, arising from dampness in the sheath after blooming, and what treatment is advisable, besides proper ventilation and careful watering, to prevent such attacks altogether?—C.

[Whether or not a plant requires a larger pot when renewing the compost depends partly upon the habit of the species, but more upon how it is thriving. In every case it is advisable to remove as much of the old material as possible without unduly disturbing the roots. We have just been repotting some large plants of *Cymbidium giganteum*. These had completely filled their pots with roots, enwrapping firmly every particle of both compost and drainage. To have pulled these roots about would have been very unwise, as a check to the plants would have been inevitable. But these are exceptionally vigorous rooters, and therefore come in for exceptional treatment. In all ordinary cases the point you urge is quite right. With regard to the sheaths decaying on *Cattleya labiata*, either this is the result of a cold drip or the plants have been kept too moist in a lower temperature than they require. Cutting half way through the sheath in removing the flower spikes tends to this condition of things, but with otherwise healthy plants in a suitable atmosphere it would not occur. The only remedy at all likely to be successful is removing the sheath entire when the decay is first noticed, carefully avoiding injury to the pseudo-bulbs in so doing. We wish you every success in your laudable effort to excel in the culture of this beautiful and interesting class of plant.]

EELWORM ERADICATION.

INFORMATION WANTED.

I HOPE now the Chrysanthemum season is over you will give space in the Journal for Mr. Abbey to make clear his statements respecting eelworm in Cucumbers and Tomatoes and proposed remedies. Many of us market growers will soon be planting our "Cues and Toms" by the thousand. In these days of keen competition we cannot afford to do much experimenting, and then find supposed remedies useless as in the case of the 10 per cent. of lime treatment. In my experience Tomatoes or Cucumbers could not survive such treatment. I found them dead in twenty-four hours after applying 10 per cent. of lime to soil that Professor Gilchrist pronounced deficient in lime previous to using it.

I hope Mr. Abbey will see his way to write on maladies and remedies in a way that we can all understand. Unfortunately we were born too soon for participating in the advantages of such education as is available now in any art or science that a youth may wish to study, so kindly assist us by placing information before us in plain clear terms easily to be comprehended—that is the best of teaching and the most appreciated.

When are we to be favoured with Mr. Iggulden's "little sensation" that he promised Mr. Abbey long ago? This public promise remains unfulfilled. We are anxiously awaiting the fulfilment, and hope not to be disappointed. A promise made public is a public engagement. We want to hear of a remedy which will speedily annihilate the eelworm, and so rid us of this dreadful pest.

For twelve years I had no trouble with it, as at that time I used Jensen's fish manure 1 part to 100 of soil, with 1 part each of lime and soot; unfortunately, I cannot obtain it now, I only wish I could. Not only does eelworm attack Cucumbers and Tomatoes, but Cyclamens, Primulas, and Carnations suffer from its depredations.

I consider this a most important subject, and one that affects a great industry, so that we shall be very much obliged, Mr. Editor, if you will kindly insert this letter in your valuable paper.—JOHN BRADLEY.

[The letter is readily inserted, and we shall be obliged by the results of experience clearly and plainly described, in conquering one of the most insidious and destructive enemies of plants. We are bound to say, however, that many persons rely too much on "remedies" instead of taking timely action in the way of "preventives." When eelworms become embedded in the tissues of plants they are the masters of the situation. The information given on page 93 last week ought to be interesting and useful, but the manure formulæ, good as they may be, will not kill eelworm in the tissues of the plants; and we suspect it is easier to kill eelworms and their eggs in the laboratory than in the soil. The time is opportune for Mr. Iggulden to give the results of his experiments. He sent us the best flavoured Tomatoes last year that we tasted during the whole season. It would be interesting to know how long the 10 per cent. of lime had been mixed in the soil before it killed Mr. Bradley's plants.]

A WANT AND A WAIL.

POOR FLORA! Unhappy Pomona! Not even in the mighty modern Babylon, where your most ardent worshippers would fain see a noble temple rear its head, is there to be a place for you save on sufferance in uncongenial surroundings. Considering the immense importance of the subject to the gardening fraternity generally and to the higher exponents of horticultural art in particular, it is not surprising that the question has received considerable attention of late; but it must be a matter for regret to feel that we "too oft begin in pomp and show to end as little and as low." Perhaps it is impossible to sever luxuriant associations from horticultural art, hence we are carried away from the actually necessary into the realms of palatial and magnificent design—splendid dreams, never to be realised in our day; worthy, indeed, of the object, but sufficient to court defeat under the dominion of the severely practical spirit of the age.

The powerful stimulus afforded this year to our loyal and patriotic feelings will doubtless take some practical form consonant with our own peculiar requirements. It has, in fact, already done so; but so far as this subject is directly concerned it appears to have been taken up and dropped as quickly as the proverbial hot Potato. There is no occasion to draw invidious comparisons between schemes relating to this subject and those benevolent ones which have been propounded. "The Gardeners' Royal Benevolent Institution" is worthy of all the support it will obtain, and of a great deal more than gardeners as a class have ever given to it; but great and good and noble as it is, one would like to express a passing thought upon that provided by our text ere it is relegated to obscurity. Obscurity? It may be that it is not so; that the yearly progress of gardening will increase in corresponding ratio the already keenly felt want, and that even we may live to see Mr. Wood's dream realised. Yet all too sanguine an expectation mayhap on those lofty lines, and granted that unfortunately this is the case then may one venture to ask, Is there no *via media* worthy of attention by which the object might be gained? Ere our jubilant feelings are for the nonce wholly diverted into other channels, however praiseworthy, this horticultural building scheme should not, I think, be wholly a shattered idol.

There are, I suppose, but few exhibitors who have not felt the want we are dealing with, and to most horticultural societies it is the one thing needful—viz., a permanent building adapted to the purpose in which they may be practically independent of the weather and not dependent at any time upon makeshift lodgings. Truly there is nothing more pleasing to all concerned than a battle under canvas in balmy weather, but when it comes to a battle with the elements which too often reign (rain) triumphant there is nothing more depressing—a depression seriously affecting the receipts. On one occasion our Society, which had pitched its tents in congenial surroundings, was worsted in the encounter with Boreas, who literally drew a curtain over the scene by bringing down poles and canvas at one fell swoop on specimen plants, flowers, and fruits. Too often have circumstances compelled me to stay under a dripping tent sharing the honours with the bands-

men, who, huddled up in greatcoats, endeavoured to do their duty by the occasional tootling of a muffled march.

To complete a dismal picture and sharpen the point of the moral one instance may be added of an experience which was absolutely startling. "Beggars must not be choosers," and pecuniary considerations are weighty ones to a society with a light exchequer. As an exhibitor I had on various occasions participated in the advantages afforded by the gratuitous use of a noble building which answered the purpose very well indeed. On a never-to-be-forgotten day, eager to escape from the "madding crowd" and the brassiest of brass bands, I wandered through a side door into regions where I certainly had no business and found no pleasure. Encountering a garrulous official connected with the building, whose desire for baksheesh—coupled with some homage paid to Bacchus—had overcome his discretion, he asked with a maudlin air of mystery, "Would I like to see something? If so, come along." So I went "along," and saw "something"—a dozen "somethings"—which, however necessary in the interests of surgical science, were ghastly to contemplate in juxtaposition to the gay and festive scene of a flower show. Sickened and sad I returned to the halls of life and gaiety after plenshing the palm of the beery janitor, who, turning the key on this chamber of horrors, kept out, I sincerely hope, further trespassers.

Yes; undoubtedly we do want suitable temples to enshrine our gardening handiwork when occasion demands; and to come direct to the question one might infer that such things are possible of attainment, and of all places one might, moreover, reasonably expect London to lead the way. If we cannot have what we would like—the luxuriant

temple—and can never like what we have to resort to, why not consider the actually necessary ere all hope is abandoned of immediate progress in this direction? Given a suitable site—or the most suitable attainable—what then? Something to make it independent of the weather. Canvas being out of the question, the next suitable material suggesting itself for the purpose is timber and glass, or iron and glass—a winter garden, in fact, not rising in palatial domes, for such apparently are only practicable on paper. But fatal objections have been raised against the use of glass in a smoke-laden atmosphere. Might not this be overcome in a ridge and furrow roof by having the furrows (gutters supported on the columns) of sufficient width to allow freedom of access for cleansing the blackmoor periodically? To repeat the idea, simply covering in our imaginary area on the Paxtonian principle of ridge and furrow with the necessary accompaniments of heating and ventilation, with no pretensions to the palatial and no aspirations but the essential.

"What an ugly thing this horticultural hall would be" is remarked. Could be, undoubtedly, with any attempts at elabora-

tion of detail; but simply adapted to the purpose less all pretensions to anything else, there is the necessary—there is, in fact, beauty in all things according to their fitness of purpose. Certainly you could not drop this glass market by the side of St. Paul's, and I am not competent to say where it could be placed—or, in fact, could not be placed—for such would not enter into competition with any stately buildings or any preconceived plans which seem fated to fall through. Whatever plans are projected the main object is, of course, the first consideration, the next being some catering for the public taste in due allowance of space for the musical adjunct, which appears to be indispensable, many of our patrons including those "who to the show repair, not for the doctrine but the music there." Here, I think, we may venture to draw the line, and not house our twin goddesses in a palace of varieties.

As a permanent place for its purpose we may suppose that

various details, such as planting the supporting pillars with trailing or bush plants of a semi-hardy nature, would be a welcome addition to the staging effects of competition, and even such things as Lily-decked pools or fountains with rockwork margins would be a pleasing feature, neither costly nor irrelevant. Under the roof of such a building our often foreshortened exhibitions might well be prolonged so far as plants and plant groups are concerned, for the admirable taste, skill, and labour expended upon them by exhibitors in the latter section is of sufficient educational value to warrant a reasonable extension, instead of the rapid dismantling after a few hours' display.

I am tempted to show a hundred minor accessories which crop up mentally, but have not the slightest doubt that a

hundred major objections would spring up side by side to choke them at their birth. Anyway, our wants are pretty clear, though this be but another of those Chateaux d'Espagne erected by—FREEMASON.

TEA ROSE ENCHANTRESS.—I am somewhat surprised to find myself saying on page 91 of the *Journal of Horticulture* that Mr. Wm. Paul's latest and perhaps most beautiful introduction, entitled Enchantress, is "worthy at least of China extraction." If the word "partly" is substituted for "worthy" my readers will understand better the meaning I intended to convey. I understand that Enchantress, which I admired greatly when I saw it for the first time at Waltham Cross two years ago, is the result of cross-fertilisation between a Tea and a China Rose, a fact which may account for its wonderful perpetuity and rare floriferousness. I hope this is only the bright beginning of a new race of interesting hybrids combining the characteristics of the Chinas and the Teas. Such Roses, by reason of their fragrance, their delicate beauty, and extremely free-flowering capabilities, would be of the greatest value for garden decoration. I hope, therefore, that Enchantress may have many successors of a similar description.—DAVID R. WILLIAMSON.

FIG. 28.—LELIO-CATTELYA NYSA SUPERBA.

DIAMOND JUBILEE PRIZES.

At the last Committee meeting of the Ulster Horticultural Society it was decided to celebrate the Diamond Jubilee of the Queen this year by offering £100 and three medals for competition in forty-eight Japanese blooms at the Belfast show, on 16th and 17th November next. The money is to be divided into seven prizes, as follows:—First, £40 and gold medal; second, £25 and silver medal; third, £15 and bronze medal; fourth, £10; fifth, £5; sixth, £3; and seventh, £2. The Committee decided to open this event, along with a few others, to gardeners of the United Kingdom. The prize is to be called the Victoria Jubilee Championship, and is presented by the Lady Mayoress of Belfast and ladies of Ulster.

PRIDE OF MADFORD AND BEAUTY OF TEIGNMOUTH.

I see by your issue of November 5th, 1896 (page 480), there is still some doubt respecting Beauty of Teignmouth Chrysanthemum. I may state that I sent the original plant, Pride of Madford, to my father, Mr. W. Hannaford, of Messrs. Hannaford & Sons, Teignmouth. The names were obliterated in transit, and I did not mention the name in my letter, but merely told them to grow a stock of it. It was thus sent out under the name of Beauty of Teignmouth, and also mentioned a Colonial-raised seedling. It was raised by Mr. Lynch, then gardener at Madford House, Towak, a suburb of Melbourne.

I see in the same number a communication by Mr. T. Pockett. He is a regular enthusiast, and far and away ahead of any other grower in Australia. He has brought Chrysanthemum growing to a great pitch. Last season we had some good seedlings raised here, and I firmly believe Victoria will take the lead in sending out new varieties, as our climate is one of the finest in the world for hybridising and the saving of seed.

I have seen far finer blooms here than at home—that is, ten years since. No doubt improvements have been equally as rapid in the Old Country. I am the horticultural editor of the "Weekly Times," and also on the agricultural staff. I read your paper with great interest, it being quite an old friend.—FRANK HANNAFORD.

[We are very much obliged to Mr. Hannaford for his letter and clear explanation on the subject, and shall be pleased to hear from him again on Chrysanthemum matters and progress in Australia.]

CLASSIFYING INCURVED CHRYSANTHEMUMS.

THE members of the select Committee of the N.C.S., who were appointed to endeavour to settle the above question, have taken a decided step; but whether they have satisfied themselves, let alone the outside public, is a question I much incline to doubt. I openly confess I am not satisfied. When Sir Trevor Lawrence is classed as a Japanese, and Harold Wells, which is a sport from Sir Trevor (and exactly the same in every respect, except colour), had an equal number of votes for and against as an incurved, and the Committee consisted of seventeen members, I am puzzled. Did one member vote both ways? for he surely could not be neutral on a question (as an expert) which he was asked to decide.

Another question seems rather perplexing. If Ma Perfection, Perle Dauphinoise and Egyptian are to be shown as incurved, where will Louise, Miss M. Simpkins, Philadelphia, Mrs. Libbie Allen, Boule d'Or (1895), Challenge, Ada Spaulding, Goliath, J. W. Moorman, Madame Ad. Chatin, and many others, come in?

The Egyptian has incurving florets certainly, but will Messrs Lees and Mease ever stage it in their forty-eight incurved at the N.C.S.? The colour is the only point in its favour. Size ought to count for something certainly, but a neat Mrs. George Rundle, in my opinion, would count more than a rough Egyptian, which is a very late variety, and first crown buds are nothing but quills. Even later buds are quilled half their length (see rough bloom enclosed). In my opinion judges will be more hampered than ever, especially if they are minus the confidence of a "Molyneux." I have heard Mr. Molyneux remark, "If it is staged as a true incurved I give it the benefit of the doubt."

But now comes the point, What about those varieties which have been certificated by the Floral Committee as incurved or Japanese, because the Select Committee have reversed some of their decisions? It will prove chapter 28 in my "Book on Mums," although it was a bold adventure. But good as the members of the Floral Committee may be, as a Committee, have they all, each and every one, grown Chrysanthemums—i.e., sufficiently well to vote with confidence? I really do not mean any offence, Sir Trevor Lawrence was raised from seed in these nurseries. Harold Wells sported from it before it was distributed, and I defy anyone to see the difference in them in any other way except colour. Hence my objection, but the Committee have my best wishes all the same, for I know it is hard to please all, especially—W. WELLS, Earlswood.

[The specimens of Egyptian, as might be expected at this season, are small and loose. On one point, however, there can be no doubt, every floret displays the characteristic twist of the Japanese that is not seen in true incurved Chinese varieties.]

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual dinner of this Society was held on the 2nd inst. in the Masonic Hall, Surrey Street. The chair was occupied by Mr. C. E. Jeffcock, the President of the Society, who was supported by Mr. C. E. Vickers, Mr. A. S. Jarvis, Mr. W. Atkinson, and others. There was a large attendance of members and friends, amongst whom were Messrs. F. W. Littlewood, J. G. Newsham, S. W. Seagrave, J. W. Jarvis, W. P. Atkinson, R. Crosland, J. Haigh, W. Housley, the Secretary, and most of the officials and members of the Society to the number of 100. Delegates attended from the Floral and Paxton Societies of Wakefield, Leeds, Rotherham (two societies—viz., Gardeners' and Floral), Sheffield (Floral), and Walkley. The tables were decorated with plants and cut flowers, and almost the whole of those present wore on the lappels of their coats a choice Orchid or other flower.

The usual loyal toast, "The Queen and Royal Family," was proposed by the President, who referred to her "Diamond Jubilee," and Her Majesty's expected visit to Sheffield in May. The toast was honoured with the usual enthusiasm and loyalty that it always receives in Sheffield. The complimentary toasts next received attention, the first being "The Presidents, Vice-Presidents, and Patrons of the Society," proposed by Mr. J. W. Jarvis in a very appropriate speech, reference being made to the valuable assistance of the President, who was always ready to assist the officials in furthering the interests of the Society. Mr. C. E. Vickers (Vice-President), in his reply, wished the Society every success, and said no other source of recreation was so good, pure, or elevating as the cultivation of flowers, and that nothing was so highly and generally prized as a gift of flowers, esteemed by young and old, rich and poor. Mr. F. W. Littlewood proposed the "Visitors and Kindred Societies," and gave a welcome to all present. Mr. T. Gartery (Rotherham) and Mr. W. Cawsall (Walkley) responded in suitable terms.

"The Sheffield Chrysanthemum Society" was entrusted to Mr. A. S. Jarvis, who congratulated the Society on its financial position, there being a balance in hand on the general account of £80, and one of £50 in favour of the benevolent fund connected with the Society, and also on its possession of its excellent library of works on the varied branches of floriculture, horticulture, and kindred subjects, the gift of the Hon. Treasurer, Mr. H. Broomhead, F.R.H.S. He also spoke of the numerous advantages of the Society generally. His speech was very effective, and was well received. It was duly acknowledged by Mr. J. G. Newsham in appropriate terms.

Mr. W. Housley (the Secretary) proposed the "Nurserymen and Non-competing Exhibitors," and thanked them for the assistance they always so freely rendered at the annual exhibitions. Mr. W. Atkinson (Fisher, Sons and Sibray) replied in a very able manner, and recommended the officials not to lose sight of other flowers in growing and exhibiting Chrysanthemums, and referred to other beautiful flowers that bloomed at the same time worthy of notice. Mr. R. Crosland (Crosland Bros.) also responded. The musical portion of the evening's entertainment was highly satisfactory.—J. H. S.

ENDIVE.

SALAD in some variety is expected to be forthcoming from the majority of good gardens, almost if not daily throughout the year. Where this is so, more than ordinary effort is required to furnish it during the winter months, and until spring Lettuce, Radishes, and Cucumbers are available. Endive plays an important part in meeting this daily demand—indeed, in a number of gardens it would be absolutely impossible to supply salads without it. It is quite true that Endive is not so generally accepted as Lettuce, and with many there would seem to be an acquired taste needed, much in the same way as Tomatoes, before it receives its due appreciation.

Although it may not be necessary to provide for so long a season, it is possible to have Endive for nine months of the year, August to April inclusive; but it is not certain that a succession will be maintained until the latter month. Usually under glass it commences to "bolt" in February and March, earlier or later according to the conditions under which it is grown. At that season it is very impatient of fire heat or pent-up solar warmth, and even in cool houses it is prone to run to seed early. It is only by late sowing on a border outdoors, where it may remain, that it can be depended on for late cutting, and even then it is at the mercy of the weather.

Only once in four seasons have I been able to maintain a supply so late as April, although the attempt has been made in regard to sowing. What may happen this season cannot yet be decided. The sowing was made, the plants at present are very small, too small in fact to give any assurance of what may result. The seeds were sown in the beginning of September, but that being the wettest month of the year the progress of the plants was slow, and has been so ever since. A previous autumn being favourable the plants became too large to stand frost, and the winter of 1894-5 was such that required something very much stronger in constitution than Endive to escape from being frozen to death.

The early portion of the crop is usually the best, and the easiest one to provide, as this has the favour of the late summer wherein to develop a good head, and for which there is generally sufficient accommodation in cool or heated pits where the plants are safe from damaging frosts and heavy rains. But it would need a considerable pit room to meet a fairly large demand from September till March. In my case portions of the

indoor fruit borders have to be devoted to this winter salad, as well as spare pits, and under the shelter of walls they occupy narrow borders at the present time with a hope of being turned to profitable account later on. It is true there is a larger number of late plants this season than usual, from the fact that a quantity of seed remained in the soil and did not germinate until the autumn rains set in, and for the same reason most of the plants were, and are now, undersized.

Small sowings are commenced in June, and continued bi-weekly until August, with a special one made for standing outdoors as previously intimated at the end of August or early in September. This is my practice, but it must necessarily be modified to meet the requirements of other more northern or southern counties; indeed, it is a matter that can only be governed by individual circumstances, and proved on the spot.

Endive without being blanched has no value except for cooking purposes, and there are various means adopted for carrying this out in varying degrees of excellence. Much the best coloured I have seen were taken from the Mushroom house, and some, I daresay, will be prepared to argue that this structure is not always or in every case suitable. The plants are extremely liable to decay in the process of blanching, and if new beds are being made up periodically there must be an accumulation of steam, and, on the other hand, there is a difficulty in getting just the right condition in the soil to accommodate them. Overhead watering to settle them in the soil has been known to prove quite fatal, and shrivelling sets in if they do not get sufficient moisture. Inverted flower pots, with the drainage holes closed, answer very well, and dry boards laid on the rows of plants bring them to a useful state in a comparatively short time.

In pits or frames the lights may be covered with mats or straw to keep them dark, but none of these methods answers so well with me as tying up each plant with a strand of raffia. I am informed that this is the course adopted by some of the French growers, who send such excellent salad to our markets.

The green and moss-curl are very pretty when nicely blanched, and add a feature to the dressed salad, but the broad-leaved varieties are those which find the most favour, and are grown in greater quantity. These possess in a lesser degree the bitterness which is the complaint commonly lodged against Endive as a salad. The curled sorts cannot endure frost nor defy the damp so easily as the Batavian, but notwithstanding these failings they are admired for their beauty when presented in their best form, apart from utility.

Lettuce of the Cabbage section are not appreciated by my employer at any season, so that the necessity for Endive for keeping up a long succession of salad is very important, and Cos varieties grown, as often advised, on the Mustard and Cress principle would not take its place. When Spinach is scarce Endive is often required to take its place, and this frequently happens when the latter is getting short, and can ill be spared for the purpose. After trying several varieties of the broad-leaved kinds I have come to the conclusion that the improved round-leaved Batavian, when a good stock is obtained, cannot easily be beaten; but at the same time I would not advise anyone to abandon any other variety which may have given satisfaction, because results are not strictly uniform in the case of sorts growing under varying conditions. Of the moss and curled there are not such a large selection, and thus the choice can be more easily made.—W. S., *Wilts.*

CARNATIONS AT RANGEMORE.

EARLY one morning a young friend, yes, and an old friend too, started for Rangemore. It was by moonlight, but three hours later than we intended starting. I remarked while wending our way to the station, the moon looks cold, at which my companion laughed, for he has not been in the habit of watching the moon in the country. He will not forget his visit to Rangemore, for the day turned out piercingly cold, a biting wind and heavy snowstorm kept us company all day. In spite of the drawbacks of the weather we were abundantly rewarded by what we saw under the charge of Mr. Bennett.

It is not a description of Rangemore that I am about to write, for there is an enormous amount of glass. It is about the Carnations, which we went purposely to see. My friend had seen a noted collection a short time before, but the plants though good and numerous were small. What he saw at Rangemore he considered "giants for their age." This is perfectly correct, some of the plants, Malmaisons especially, are enormous. I have never before seen in the early days of January such a display of Carnations. These plants are never showy, but the house was perfectly gay.

When I last wrote of Carnations at Rangemore a fine span-roofed house, 80 feet long and 20 feet wide, was being erected for them. This had a division in the centre, and was full of plants flowering and coming into flower, one division being filled with what may be termed Tree varieties, and the other with pink Malmaisons—a very fine strain. The latter contained Princess May, flowering profusely; Churchwarden and other new kinds were represented, only one or two plants of the old flesh coloured being grown.

Instead of a description, I am going to point out how these grand plants are produced, and the management they receive. I am writing from memory, and if I should write anything that misrepresents Mr. Bennett's practice I hope he will put me right. The plants are raised by layering in low frames in July. At one time the strongest of one-year-old plants were selected for this purpose after producing one bloom. Now I believe the weakest are layered. The strong, healthy constit-

tion of the stock has been obtained by layering strong shoots only. Do not misunderstand me when I say the weakest are selected. The best plants are potted on, the others layered; none is weak, all are strong and even robust. After the layers are well rooted they are placed in 3-inch pots, kept close to the glass until they are well established and the pots fairly full of roots. Plenty of air is given to maintain sturdy growth.

From these pots the plants are transferred into 8-inch. A rather large shift some may say, and so I thought, and consequently placed mine of the same age into 6-inch. The results prove that Mr. Bennett is right, and for the future I shall work on the same principle. At this period of the year the plants look overpotted, and the apparently dry condition of the soil would certainly frighten some growers. When these healthy plants in 8-inch pots do start they develop wonderfully, and continue to do so through the flowering stage, while those in 6-inch pots are too full of roots, and are somewhat checked before the flowering stage is over. This is what I observed with my own plants last year. The specimens in 8-inch pots are arranged in span-roofed houses close to the glass as possible, and the pots sufficiently far apart so that they can be carefully examined for water.

Under these conditions the plants grow until they have flowered, the best being selected and placed into 10-inch pots. Those are the plants that flower in autumn, continuing throughout the winter and spring. As far as I can understand, they are kept the whole year under glass, and only shaded for a few hours daily during the very brightest sunshine. What are these plants in this size pot like? is only a fair question to ask. The foliage is of the darkest green, very glaucous, and wonderfully strong. The plants have from fifteen to twenty-two shoots—think of that, and little more than eighteen months from layering. They may be described as being 2 feet 6 inches high and 2 feet through them. They are, indeed, marvels of cultivation.

The syringe is not used in any stage of growth, but the most careful watering is practised. Those who had to grow hardwooded Heaths, or assisted in doing so, years ago, will know how these Carnations are watered when I say the principle might be described as the same, but for the benefit of younger gardeners I may say the dry appearance of the top of the soil is no guide, while the ringing of the pots is not merely followed. The pots are lifted principally to ascertain if they need water; in a word, an intermediate state for moisture, as far as possible, is aimed at. The plants are kept during the season of inactivity on the dry side. The soil looks dry, but it is never allowed to become destitute of moisture to injure the roots before water is applied. When they do need water a good soaking is given, not a mere dribble.

Ventilation is abundant at all times; no close confined atmosphere is maintained at Rangemore, and this is one of the secrets of success. On the day of my visit, in spite of keen frost and a biting wind, the flowering house had the side ventilators open about 2 inches on each side, and the temperature maintained was from 50° to 55°. The atmospheric conditions were such that these plants could grow slowly, but the growth made would be at the same time of the sturdiest description. Soft weak growth forced out by heat and a close confined atmosphere is detrimental to a healthy constitution, and means puny flowers, while the plants are a ready prey to disease—one cause, if not the main cause, of so many plants being diseased in the majority of gardens.

The soil I am not quite certain about, beyond good fibrous loam, which forms the principal, and coarse silver sand. Great care is also taken to free the loam from wireworm and other insect pests by stacking it in a position under cover for a time until it becomes thoroughly dried; when broken up water being used to once more render it in a suitable condition for moisture. The pots are carefully, even liberally drained, and the soil pressed firmly into the pots. No light material for potting is used, and loose potting is not practised.

Does Mr. Bennett feed these plants? Certainly, on the surface of the soil when in the 10-inch pots freely by the aid of artificial manure. I think I may safely mention the manure, although I always try to avoid doing this. Clay's is the kind used. To be successful no treatment must be followed that has a tendency to weaken the strength and vigour of the plants. These are the outlines of Mr. Bennett's treatment, and the result is no finer plants to be found anywhere, and the yield is abundance of large well-coloured flowers. How the tree varieties are treated shall be given another time.—WM. BARDNEY.

(To be continued.)

TREE PÆONIES.—Amateurs usually have a number of plants which grow to some little size, and which are known as tub-plants, that are easily transferred during the winter and yet form striking beds when placed in judicious situations on the lawns in the summertime. Oranges, Lemons, Hydrangeas, Oleanders, Yuccas, Pomegranates and other similar plants will readily come to the mind of the reader. One of the most desirable of this class of tub-plants is very rarely seen—namely, the Tree Pæony. As usually seen in gardens, they do not make much of a show, because it takes many years before they can grow to large specimens. Each shoot only makes two or three buds a year, and each of these buds will make a flower the year following; but, in five or ten years, a bush in flower presents a striking appearance. A large Tree Pæony is usually considered of great value. A ten or twelve year old plant would be worth nearly as many dollars as it had been years growing. It is a never ceasing object of growing interest.

THE YOUNG GARDENERS' DOMAIN.

THE R.H.S. EXAMINATION.

IN "A Student's" excellent advice given to young gardeners who wish to sit for the R.H.S. examination he says that "All candidates wishing to sit must send in their names to the Secretary not later than the first week in February." Is this not a mistake? I communicated with the Secretary some time ago and received a form in reply, which was to be filled in and returned not later than March 16th. If it is a mistake I think it advisable that it should be corrected, or many would-be examinees may give up the idea of sitting this year, being under the impression that they are too late.—W. R. R.

TESTING EARLY TOMATOES.

I SHOULD like to say a few words on the two following Tomatoes—namely, Sutton's Earliest of All and Frogmore Selected, which we grew side by side last season. The seed was sown singly in small pots the 9th of December, 1895, and placed in a house with the temperature of 50° to 55°. As soon as the plants appeared they were moved to another house with a temperature of 60°. There they remained on a shelf near the glass until the 22nd of January, when they were transferred to 5-inch pots. When almost touching the glass they were shifted into 12-inch pots. When about 4 feet 6 inches high they were topped, and also top-dressed with fresh soil, and eventually, when the pots were full of roots, supported by liquid manure. Sutton's Earliest of All ripened two days before Frogmore Selected, the first fruits being gathered on the 24th of April.—L.

"THE VICTORIAN ERA FUND."

MAY I be permitted a little space in the "Young Gardeners' Domain" to refer to the above subject? In the *Journal of Horticulture*, January 21st, I read with interest Mr. Veitch's appeal to all gardeners to help in raising a sum of £5000, "the income from which shall be devoted to affording temporary assistance to those applicants who are waiting to be placed on the pension list" of the "Gardeners' Royal Benevolent Institution." I should like to suggest to all "Bothyites" that each one give what he can, and let the foreman or someone who collects, send the full amount to Mr. H. J. Veitch. I think a good sum of money might be collected towards the fund by the young gardeners of Britain if they would combine for the purpose. I hope to collect and send a little from the bothy I am in at present.—YORKSHIREMAN.

[If every young gardener would give even a shilling it would amount to a goodly sum—a day's wage from gardeners, old and young—would make a noble contribution.]

AZALEAS.

AZALEAS, I think, will always be favourites, for scarcely another race of plants exists that produce such a quantity of flowers as these do when grown to perfection. Wherever a number of these plants are grown for conservatory or house decoration they give what is probably the finest display of blooms obtainable throughout the year. Azaleas are also most useful for cutting purposes, such as dinner table decorations or bouquets.

After the plants have done blooming, and all the withered flowers are cleared off, the younger plants should be repotted and then placed in a house with a temperature ranging between 50° to 60°, with plenty of air when the weather is favourable, syringing morning and evening. When they have finished their growth the temperature should be gradually lowered, until they can be removed out of doors to ripen the wood, but should be placed back in a cool house before the frost sets in.

The soil generally used in the gardens I have been in is this—namely, three parts of good fibrous peat, one part of light loam, one part of leaf mould, and one part of silver sand, with a light addition of artificial manure, such as Clay's or Thomson's. In draining the pots we had to be very careful, covering the bottoms nearly 4 inches.

Azaleas, if not kept well syringed, often cause trouble through attacks of thrips or green fly. These pests can be destroyed by fumigating with tobacco paper; but I think young gardeners ought to get the head ones to procure the XL fumigators, as I am one who does not like tobacco smoke.—W. L.

POTTING CATTLEYS.

(Continued from page 102.)

IF established plants were potted properly in the first instance very few will require pulling in pieces, but if through inattention the growths are near the edge of the pot, and the centre empty, they should be divided and put together properly. If the plants are well rooted the pots should be broken and the pieces picked away, but when they cannot be separated without injuring the roots they may be left on. If large crocks were used in the previous potting, two pieces of raffia tied around the ball so as to cross over the rhizomes and underneath the crocks will keep all in place, but if small crocks were used most of them will fall away, and it will injure the roots to fill them in again. With large plants it is advisable to measure the old ball with a stick and the inside of the pot as a guide to the depth of crocks will be wanted in the bottom to have the plant its proper height when in position. With the long potting stick the crocks can be worked into their places until the pot is filled to the required height, finishing with compost as advised for imported plants.

Cattleya Bowringiana should be potted a little higher than the others, as each growth it makes is lower than the previous one. This is the only variety I know that grows down to the soil except Cattleya citrina.

If these are potted in the same manner as other Cattleyas they make their growth lower each season, and turn their heads downwards, which is their nature. Some growers place them on rafts in their natural position. They should always be suspended from the roof, which is the best place for the choice varieties.—A SECOND OF THREE.

SINGLE DAHLIAS FROM SEED.

To obtain strong plants for autumn flowering seed should be sown now or before the middle of the month in a compost of loam, leaf mould, and sand, in rather deep pans, and placed in heat, about 60°. If the seed is good the seedlings will appear in about a fortnight. When large enough to handle they should be placed in 60-size pots, using the same compost as before. Place them on a shelf near the glass, shade from bright sunshine, and syringe to keep down green fly. As soon as the roots touch the sides of the pots the plants should be pinched. They will then soon push out three or more side shoots; they should then be shifted into 48-sized pots, this time adding a little more loam to the compost. They may be placed near the glass in a frame on a half-spent hotbed, shading a little at first, always using the syringe freely on closing the frame, and in due time top them again.

About the middle of April they will be ready for their final shift into 32-sized pots, some into larger, according to the size and strength of the plants, using a compost of three parts rough loam and one part spent Mushroom bed refuse, adding a good portion of sharp sand. Again place in a frame and keep close until growth has commenced, when air should be admitted through the day. Syringe and close the frame at night. Pinch them once more, gradually harden, finally removing the lights altogether.

By the middle of June the Dahlias will be ready to plant out. Place a little well decayed farmyard manure in the bottom of rather large holes, covering with soil, so that the roots do not come directly in contact with the manure. Press the soil firmly around, and support the plants with stakes. They yield abundance of beautiful flowers of various colours. These are very useful for house and table decoration, and especially church decoration, which is generally required about their time of flowering.—LEARNER.

CONSERVATORY MANAGEMENT.

(Continued from page 102.)

IN the general arrangement of the conservatory I do not favour borders along the centre of the house planted with Camellias, as is often the case. These "fixtures," if they may be so termed, from their occupying the position all the year round, appear somewhat stale, and interfere generally in the arranging of plants in pots to the best advantage. A house with a clear tiled floor is preferable to either planted borders or stages in the centre. Small borders may be formed round the sides in which to plant the climbers. These borders should be covered with clean sand, and plants may then be stood on them. Grouping is perhaps the most effectual way of arrangement for the centre of the house. Groups arranged lightly and tastefully are highly attractive.

In furnishing the conservatory it will be found advantageous to work on a system, having collections of well grown plants which will closely succeed each other in blooming. These collections will form a distinct feature at the different seasons of the year.

In January Camellias, Cytisus, Ericas, and Epacris will predominate; also Roman Hyacinths, Cyclamen and Primulas. Plants of Azalea mollis and Rhododendrons, which may be lifted from an outside border, should be put in heat. These soon expand their flowers and make a good show. Do not force too many at once, but keep a few back to occupy the places of the earlier ones. Dutch bulbs are very serviceable at this season, and no conservatory should be without them. Small quantities placed in heat at intervals of about three weeks will maintain an unbroken supply of bloom. A few Deutzias may also be put in gentle heat to be steadily coming on. Amcena Azaleas force well, and are also very useful. During this month the house should be kept at a temperature of 50° to 55° in the daytime without sun, allowing it to fall 5° or 10° in the night. Attention must be paid to ventilating on favourable occasions.

In February the conservatory will be gay with the same kind of plants as in the previous month, continuing into March, Cinerarias being the chief addition. These plants having been raised from seed sown in June, and having proper cultural treatment, should now be in full bloom. They will make very good substitutes for the Epacris, and many of the Heaths, which by this time will be ready for removal. The Epacris and Erica hyemalis should have their fading flower shoots pruned back to about an inch from the base, assigning the plants a light position in a cool house, but kept rather close until growth is a little advanced, when air may be freely admitted. A light dressing with Standen's manure will assist the plants in making growth. A few Hyacinth, Tulip, and Narcissus bulbs should be put in a cold frame in order to keep the flower spikes back as much as possible, and so prolong the supply. Shade them from the sun and admit air freely.

By the end of the month of March, or early in April, the Camellias and many of the forced plants will be ready for removal. Ghent Azaleas and Rhododendrons should be still kept in a little heat until growth is complete, when they may be again planted in an outside border. Camellias should also be placed in a warm house (an early vinery being very suitable), and liquid manure given to stimulate growth.

Having cleared all plants which are unfit for further use out of the conservatory, the climbers should next be attended to. Pick out all

dead leaves and cut away any dead wood. Those attacked by any insect pest should be cleaned and afterwards neatly tied. This work being completed the house should be cleaned before the succeeding plants are put in.—P. W.

(To be continued.)

VINES—STARTING TO FLOWERING.

AFTER the Vines have been pruned they should be untied and taken down from the wires that the house may be thoroughly cleaned. Soft-soap and hot water applied with a scrubbing brush is best for the woodwork, and clear warm water only for the glass. It is a good plan to peel the old loose bark from the Vines when cleaning them, as it harbours many insects. In doing this care must be taken not to injure the under bark. A solution of softsoap and hot water with a little petroleum added (a wineglassful to 2 gallons of water) forms a good mixture for washing the Vine rods. Be careful to clean out all holes and corners, especially around the spurs. This work cannot be too thoroughly performed, as if it is not well done much trouble and labour will be caused when the Vines are growing.

As soon as the house and Vines are finished attention should be directed to the borders. First remove the surface soil about 2 inches deep, to get rid of any insects that may have fallen from the rods during the cleaning of them. If plenty of roots are found a top-dressing of good loam with some bone dust added would be very beneficial. If no surface roots are visible, simply spread a little artificial manure on the border and dig it in lightly with a fork, stirring up the soil to the depth of 3 or 4 inches. To protect the outside border from frost and rains it should have a good covering of long stable litter.

Before starting a house examine the borders to ascertain if they are dry, and if such is found to be the case give them a good watering. In order to induce the Vines to break evenly, at the time of starting they should be bent in a semicircular form, and tied along the front of the house. By doing this part of the sap is directed to the back buds instead of its rushing to the top of the Vine, which would happen if they were tied up perpendicularly.

The treatment of forced Vines depends a great deal upon the time of the year they are started. Those started in November or December would require longer to mature their crops than others started in January and February, as naturally they would not grow so quickly during the dull, dark days of winter.

I will take as an example a vinery from which Grapes are to be cut by the end of April. A period of about six months is necessary to produce ripe fruit for that season. A start, therefore, should be made early in November. Little or no fire heat will be required to maintain a night temperature of 48°, which is sufficient to begin with. In dull, cold weather keep the day temperature about 58°. With sun heat the thermometer may be allowed to rise to 65° before giving air. To produce a moist atmosphere the house must be damped down and the Vines syringed several times a day, according to the state of the weather.

After a month has passed increase the night temperature to 55°, and allow a corresponding rise during the day. In a month or five weeks from the time of starting, the buds will show signs of bursting. When the shoots are 2 or 3 inches long the Vines should be tied to the wires, but leave the ends loose and hanging down for some time longer to still act as a partial check to the rising sap. The young growths quickly increase in size and strength now they have more light and room. They will soon need tying down to the trellis to keep them in place and away from the glass. By the end of December the Vines should have made good progress, and a temperature of 60° at night, rising to 75° by day, will not be too hot for them. The syringe requires careful usage at this stage, as the young shoots are very tender and easily broken.

It is seldom that much disbudding is necessary in the case of early forced Vines. The shoots bearing the best bunches must, of course, be retained, and all weak and superfluous ones removed. When three leaves have been made beyond the bunch it is usual to pinch the shoot at the first or second leaf, but this and stopping of laterals will depend upon the space to be covered. The foliage must not be crowded, or it will become stunted and unable to properly develop.

Towards the end of January or the beginning of February the Vines will be in flower. During this period a dry buoyant atmosphere should be maintained with a night temperature of 67°, rising to 80° by day with sun heat. It will considerably help the setting of the flowers if the Vines are shaken every day in order to distribute the pollen. A camel-hair brush is generally used to fertilise the flowers of some varieties deficient in pollen.

I have not yet made mention of the insect and other pests which often attack Vines during their growth. Those most generally met with are the red spider, mildew, thrips, and mealy bug. The first-mentioned is often produced by keeping the atmosphere of the house too hot and dry. As a preventive endeavour to produce the opposite state of affairs by well syringing and damping, especially near the hot-water pipes. As a remedy dissolve half a pound of softsoap in 3 gallons of water, together with a handful of sulphur, and well syringe the infested parts with the mixture. This treatment is also effective for destroying thrips.

Mildew is a very troublesome pest, and if allowed to spread greatly disfigures both the Vine and its fruit. Cold draughts and low temperatures are the chief factors in its origin. Sulphur is the best known remedy. There are various methods of applying it. Flowers of sulphur may be dusted on the leaves and bunches, or made into a paste and smeared on the pipes. These, however, must not be overheated, or the

hot sulphurous fumes resulting would cause serious damage to the fruit and foliage.

Mealy bug is difficult to eradicate when it is once established in a vinery. As I before mentioned, the old bark should be peeled off and the Vine washed with a solution of softsoap and hot water, adding a little petroleum. Many of the insects may be caught when the Vines are moving, if we are on the alert, with a brush dipped in petroleum.—H. H.

[Setting and thinning Grapes next. Can any of our probationers send sketches of properly and improperly thinned bunches of Grapes?]

SOLANDRA GRANDIFLORA.

To convey an idea to "A. P." we give herewith an illustration (fig. 29) of this plant, which is rarely met with. This is not, however, because it is not beautiful, but rather that it is somewhat shy in producing its

FIG. 29.—SOLANDRA GRANDIFLORA.

flowers. Besides the flowers being strikingly attractive by their Brugmansia-like form and pale yellow colour, the foliage is also agreeable, and the plant is worthy of being cultivated by amateurs in their stoves. The plant is propagated from cuttings, which should be grown in loam and peat in a brisk heat and with liberal supplies of water until it has attained a good size. Water should then be gradually withheld until the leaves wither and drop off by drought, and the plant will seldom refuse to flower profusely. It is a free-growing plant and a native of Jamaica, thus requiring heat to grow it, yet a distinct season of drought and rest to induce the production of its beautiful flowers.

HARDY FRUIT GARDEN.

Planting Fruit Trees and Bushes.—Fruit trees of varied forms and sizes, also small bush fruits, may still be planted. Choose the driest periods which occur in the course of the present and succeeding month. They will succeed well if planting is carefully carried out, presuming that due attention is given to the preliminary details regarding the soil and the treatment of the trees. The demands of the trees in lifting and replanting should be carefully studied, so as to avoid checks to the future growth. The most important matter, and one that is frequently overlooked, is to prevent the roots becoming dried by cold parching winds, or lying exposed to the sun.

Preparing Ground.—The position for planting is best if previously prepared in autumn by deep digging or trenching, in order that the soil, if light and rich, may have become consolidated. Firm ground suits fruit trees better than soil lying very light and open in texture. Autumn preparation is strongly recommended for heavy retentive soil. It absolutely requires a period of exposure to atmospheric influences. This is best secured by thoroughly breaking up the soil and subsoil, allowing frost, rain, wind, and the changes of temperature to act beneficially upon it. In spring, as soon as the surface dries sufficiently, forking it over will render it more workable and suitable for planting. When it is necessary to prepare the soil and plant shortly after, the site chosen should be neither light nor heavy, but fertile soil of a medium texture. In some cases the ground needs but little preparation, the high cultivation accorded to a preceding crop having brought it into a desirable condition, a level surface only being required.

Excavations for Planting.—After the space has been marked out, and the positions for planting indicated, excavations for the roots should be prepared. They must be wide, in accordance with the length of the roots. Comparatively shallow holes are required, or of a depth that the bole of the trees when planted will be no lower in the soil than before, as indicated by the earth marks on the stems.

Character of Trees.—The most suitable trees for planting now or at other times are those furnished with abundance of fibrous roots. Strong roots bare of fibres ought not to predominate. They are not so essential as a more plentiful supply of the weaker roots which have numerous rootlets attached. The latter more readily take hold of the soil, thus rendering the trees or bushes more quickly established.

Treatment of the Roots.—The transference of young trees from one part of a garden to another does not cause much mutilation of the roots if extra care is taken in lifting, so that plenty of soil adheres. The work can be done expeditiously, so that the roots are not dried. The treatment of trees received from nurseries depends on the method of packing. The best firms pack the roots carefully. All they require is to cut smoothly the bruised and broken ends after unpacking, and lay the trees in quickly in moist soil until they can be finally planted. Trees that have very dry roots from any cause should be immersed in water to assist in freshening the flaccid tissues. Roughly dug up specimens have many broken and injured roots, which should be cut smoothly above the points where damaged. Cleanly pruned roots sooner push forth new additions, which in their turn originate young fibres.

Planting.—The disposal of the roots in the soil is of importance to encourage a good start. Spread them as much as possible horizontally with layers of soil between, not crowding them in a mass or fixing them in a vertical direction. Place the trees on a slightly convex-shaped mound. Employ the best of the soil for spreading among the roots. Suitable material may be made by crushing it moderately fine and intermixing with a proportion of wood ashes or burnt refuse.

Pruning.—Shortening the branches is most essential with young trees, and when the roots are few. A tree with few roots cannot support the first season long branches, causing every bud to start. Such as these should be shortened considerably so as to promote free growth. Trees not having a requisite number of branches must be cut closely back to obtain them in the desired positions. Well rooted trees do not receive severe checks in planting, and these need less shortening with the exception of those being incompletely furnished with branches. Apples and Pears having the terminal bud of any leading branch, a flower bud must have such pruned back to a wood bud, so that the extension of growth may continue. A suitable time to prune is when the buds commence to swell.

Staking and Mulching.—All trees which cannot resist being moved by wind must be secured with stakes and ties, not injuring the bark. Complete the work by mulching the surface with partially decayed manure as far as the roots extend.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest House.*—The weather on the whole since the turn of the days has been fairly favourable for forcing operations, and where proper attention has been given to ventilation, fertilising the flowers, and the maintenance of a suitable temperature the set of fruit is satisfactory. Any varieties still in flower should have the blossoms brushed over daily with a feather, though shaking the

trellis answers in many cases, especially when the house is kept rather dry. When the flowers fade a moderate syringing with water of the same temperature as the house will assist in bringing off the remains of the petals.

Avoid undue haste in the forcing, for success depends on sure, steady progress. Disbud cautiously, commencing with the foreright shoots first, following from the upper and upright parts of the tree downwards to the horizontal branches at the base. Shorten any bearing growths left full length in pruning to a growing bud on a level with or above the fruit. Fumigate on the first appearance of aphides, but not whilst the trees are in flower, and be careful not to give too much, as the foliage and fruit are very susceptible of injury. Keep the surfaces near the hot-water pipes moistened as they become dry, and supply water or liquid manure to the border as required. A few sweetened horse droppings may occasionally be sprinkled on the border for giving off ammonia, acting as a check to red spider, and supplying nourishment to the roots; but avoid heavy mulching, as this encourages wood growth at the expense of the fruit, and must not be given until the stoning process is completed.

Maintain a day temperature of 55° artificially, 50° at night, and 60° to 65° by day, with a little ventilation and gleams of sun, ventilating fully above 65°, being careful to avoid cold currents, and close sufficiently early to raise the temperature 10° from sun heat above the ordinary temperature.

Succession Houses.—Trees started at the new year have the flowers expanded, and will need but moderate atmospheric moisture, syringing the trees being discontinued; damp the paths and borders occasionally to secure a genial condition of the atmosphere. Trees started with the current month should be syringed until the blossoms commence opening, and where the buds are thick remove those on the under side of the trellises. Before the flowers expand it is a good practice to fumigate the house on a calm afternoon, when the trees are dry, to destroy any aphides that may exist, and so keep the trees free from these pests until the fruits are set. Inside borders must not lack moisture; therefore, if there is any doubt on this point make an examination, and give a thorough supply of water or liquid manure if the trees are enfeebled by repeated forcing or need succour.

Late Houses.—The blossoms in these have been kept back by the weather, and are generally in a healthy condition. Where the lights have been removed they need not be replaced until the time for starting the trees or the blossom buds are advanced in swelling, and it is not safe to longer expose them. Trees under fixed roofs must have the inside borders kept moist and freely ventilated, so as to keep the trees in good condition for giving full crops of fruit. Lifting and re-arranging trees in late houses may still be proceeded with, bringing such operations to a close as soon as possible, yet avoid working about trees and in borders in bad weather, for it only converts the soil into mud, and it bakes and cracks afterwards, forming an impermeable mass, or letting the water through it by the fissures.

Vines.—*Earliest Forced in Pots.*—Where the bunches are properly thinned, and not too many retained, the Vines will push laterals, but if overburdened with fruit they come to a standstill, and the fruit suffers more or less, therefore aid such Vines by a careful cutting-out of the eyes in the axils of the leaves below the bunch on each shoot, taking care not to injure the leaves. This will assist the Grapes in swelling, and may cause the shoots to push laterals above or on a level with the fruit. The laterals beyond the bunches will require pinching at every joint where the space is limited, rubbing off those below them; but where there is room those in advance of the fruit may be allowed more freedom, tying them down to the trellis.

Top-dress the soil with freshly cut turf, but the grass reduced in lumps the size of a hen's egg and sweetened horse droppings in equal proportions, adding to every bushel a pint each of soot and bone superphosphate, with a quart of wood ashes, mixing well. To maintain the top-dressing in position peg with galvanised wire reversed curves around the rim, thus forming a receptacle for the top-dressing. If the pots are standing on loose brick pedestals and fermenting materials are placed around the pots the roots will extend over the rims, and being fed with liquid manure the fruit will be finer in proportion.

Early Forced Planted-out Vines.—Stopping, tying, and thinning must have needful attention, removing surplus bunches before they have time to rob the Vines, for that prejudices the current and next year's crop. A judicious thinning of the bunches does not always mean a corresponding reduction in weight when the Grapes are ripe, and it invariably tends to good finish. Let the laterals extend as much above the bunches as the space warrants, but not allowing more leaves to be made than can be duly exposed to light, making allowance for an increase of growth through stopping. Liquid manure in a weak and tepid state may be given to inside borders; mulch with short sweetened manure from the stables, but avoid excessive quantities, as too much ammonia is prejudicial, whilst a little benefits the Vines.

Damp the house in the morning, and at closing time or early in the afternoon, ventilating a little between 70° and 75°, and keeping through the day at 80° to 85° from sun heat. Close so as to maintain that temperature, or run up to 90°, the heat at night falling to 65° or 60° in the morning of cold nights, maintaining 70° to 75° by day artificially, or 5° less if cold and dull.

Early Muscat House.—To have Muscat of Alexandria ripe in June, which is as soon as this variety may be depended on, the Vines require to be started about the middle of December, and to be brought on steadily, as in a close and moist atmosphere the foliage becomes very

thin and liable to scorch. The bunches are now approaching the flowering stage, and should have a night temperature of 65° to 70°, with a rise of 10° to 15° by day, closing for the day between 80° and 85° when bright weather prevails.

When the bunches are in flower they should be carefully fertilised, brushing over every bunch with a camel-hair brush when the caps are being thrown off, following with pollen from a free-setting variety, such as Black Hamburgh; then a good set may be expected. Madresfield Court requires similar attention, and ripens earlier and in a lower temperature than is required for Muscat of Alexandria, which requires some time in ripening, and to have the roots in a warm inside border. This may be mulched after the Grapes are set with lumpy material, through which air and water can pass freely.

Succession Houses.—Commence disbudding after the bunches show in the points of the shoots, tying the growths down before they touch the glass, stopping the bearing shoots a couple of joints beyond the fruit, and pinch the laterals below the bunch at the first leaf, and above allow them to extend, but only to cover space with foliage fully exposed to light. Remove all surplus bunches before they flower, and maintain a moderate amount of moisture, even after commencing to flower, and secure this by damping occasionally, maintaining a night temperature of 65° to 70° at that time, and 70° to 75° by day artificially, with a gentle circulation of air. If there is any lack of moisture in the borders give a thorough supply before the flowers open, but avoid making the soil sodden, as this is not favourable to setting, and often leads to shanking.

Houses to Afford Ripe Grapes in July.—In these the Vines must now be started, watering the inside border with tepid water to render it evenly moist, but an excessively wet condition retards root action, and is often followed by various prejudicial consequences, therefore a somewhat dry is better than a wet soil at the commencement. Weakly Vines may be supplied with liquid manure. Damp the rods two or three times a day, and maintain a temperature of 50° at night, 55° by day, advancing to 65° from sun heat.

Late Houses.—The Vines having been cleared of the Grapes early in January or before, pruned, and the inside border top-dressed with fresh loam, with a pint of dissolved bones and a quart of wood ashes to every bushel of loam, and the house kept cool so as to insure rest, a good or needful supply of water should be given, and a start made without much further delay, as it is essential to the Grapes keeping well that they be thoroughly ripened by the middle of September. Depress strong rods and young canes to a horizontal position or lower, and seek an even breaking of the buds by syringing the Vines two or three times a day. Keep the temperature at 55° at night, and 60° to 65° or more by day from sun heat, but ventilate freely at and above 65°.

THE FLOWER GARDEN.

Heliotropes, Fuchsias, and Abutilons.—Old plants of Heliotropes ought now to be topped and placed in heat, the side shoots from these being struck as fast as they form. A few Fuchsias, if young plants are required, to be similarly treated, but the bulk of old plants ought still to be resting in greenhouses or other cool quarters, April being quite soon enough to start these. Young shoots of variegated Abutilons taken off with a heel of old wood strike readily in heat, and in order to have plenty of these very effective bedding plants, lightly prune what stock plants there are in pots and start them in heat.

Verbenas and Lantanas.—Stock plants of ordinary Verbenas now in small pots and cool quarters should have a shift and be placed in heat. Keep them well away from the hot-water pipes, and free of other insect-infested plants, and a capital lot of sappy sure striking cuttings will then be obtained. *Verbena venosa* is best propagated by means of root cuttings. Cut the fleshy roots into 2-inch lengths, dibble these in rather thickly into boxes or pans, the topmost joint not being deeply buried, and place in brisk heat. There will soon be plenty of well-rooted plants ready for boxing off. Both kinds of Verbenas may be raised from seed, mixed beds of seedlings being very effective. Sow in pans at once, cover with squares of glass, and keep in moist heat till the seedlings appear. Sometimes the seed germinates very quickly, while not unfrequently it is several weeks before it does so. Lantanas may be raised from cuttings or seed exactly as advised in the case of Verbenas.

Koniga variegata and Lobelia.—Plants of the Koniga should be placed in heat, and the cuttings struck as fast as they can be obtained. If dwarf Lobelias are to be raised, either by division or cuttings, keep the stock plants on a warm greenhouse shelf. Subjected to a strong heat the tops soon become hard and develop into flower heads. Directly the shoots emit roots just above the soil division should take place, every partially rooted piece duly topped soon becoming a strong plant. Only sappy shoots are of any use for making into cuttings.

Polemonium caeruleum.—The variegated form of this plant now in frames or other cool quarters will soon commence to emit roots from the short stems, either buried or just above the surface of the soil, and then will be the time to divide them into as many pieces as there are crowns. Place them singly and rather deeply into 3-inch or slightly larger pots, but still keep them in a cool pit or frame, this plant being most impatient of heat, and also of drought.

Miscellaneous Plants.—Seeds of *Acacia lophantha* should be treated similarly to Cannas, and neat little plants may be obtained this spring. The seed of the Coral plant (*Erythrina crista-galli*) is equally hard, and this, too, should be soaked in fairly hot water till it has softened and swollen considerably, being then sown in previously warmed soil, and given the benefit of brisk bottom heat. *Grevillea robusta* seed

does not require soaking, but should be sown in a pan, covered lightly with fine soil, and kept plunged in a hotbed till it germinates. The quality of the seed varies considerably, sometimes germinating quickly, at others either failing to do so, or refusing altogether. Plants raised last year would be the most effective in the flower garden.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE WEATHER.

NEARLY three weeks of real wintry weather has been the means of confining the bees to their homes. In some instances the snow drifted, nearly burying the hives, and as a thaw appeared likely the snow was all cleared from them. No appearance of life was visible, the bees being snugly clustered amidst ample stores. But what a difference could be observed in the temperature of a hive containing a strong colony of bees and an empty hive. In the former the entrance was open its full width, but no snow remained for the space of several inches, owing to the warmth from the hive causing the snow to melt as it fell.

With the empty hive the case was quite different, all the snow remained close to the entrance, showing that although the heat from the inhabited hive was not perceptible to an ordinary observer, the melted snow gave sufficient proof that there is considerable warmth in a cluster of bees during severe weather. If they were examined at this stage the bees would be found in a state of stupor; there is, however, sufficient life in them to obtain food from their sealed-up stores. They are constantly on the move. Those inside the cluster obtain extra warmth, which enables them to take the necessary food. They then return to the outside of the cluster, and so the remainder feed themselves in turn.

With a change in the temperature the cluster gradually expands, and the first fine day that comes, if genial and bright, the bees will be merrily on the wing, in marked contrast to their comatose condition of only a few days before.

There is now (February 5th) several inches of snow on the level, but as there is a steady downpour of rain it will doubtless soon disappear. Already nearly 2 inches of rainfall have been registered this month; this has been chiefly snow. Frost and snow coming at this season will have a beneficial effect, as it will be the means of retarding vegetation, and warm weather is more likely to come when required for honey production. May the Queen's Diamond Jubilee year be as successful, from a bee-keeper's point of view, as the Golden Jubilee was ten years ago.

ENEMIES OF BEES.

These have been very destructive during the past month, the chief culprit being the great tit (*Parus major*), destroying great numbers of bees. If these pests were satisfied with only the dead bees that are cast out of the hives I would not interfere with them, as they destroy numerous insects; but when a dozen or two take up their abode in close proximity to the apiary they will soon clear off all stray bees which are bold enough to leave their hives on mild days at this season.

If the bees will not leave their hive of their own free will the tits are most persistent at tapping at the entrances to tempt the bees to come out. Directly they make their appearance they are seized and taken to the nearest tree to be dissected. They are not consumed bodily, but the head, wings, and sting is carefully removed, and the dainty morsel that remains is evidently much enjoyed. These birds are ever on the alert, and should be destroyed when observed to be doing damage in the apiary.

When the ground is covered with snow it is easy to see the mischief that is going on by observing the numerous fragments of bees lying about. The birds are not difficult to secure by using a spring mouse trap baited with bread or a small piece of suet. If a few of these traps are kept constantly set, and dotted about amongst the hives, it will be the means of saving many bees that would otherwise be lost.

Mice, too, are very troublesome, and if they once gain access to a hive will soon clear out the contents, and the bees not being able to protect themselves at this season will die of starvation if steps are not taken to clear off these pests. Mice will travel long distances for food, and by having traps constantly baited in readiness for them may often be destroyed before they have the opportunity of doing any mischief.

MAKING CANDY.

As some readers have found a difficulty in making soft candy for feeding such stocks as may be short of stores at midwinter and

early spring, I will state as briefly as possible how to carry it out with success. Into a brass preserving pan, or enamelled iron one, put 6 lbs. of sugar (fine granulated), one pint of water, and one teaspoonful of cream of tartar. Set on a brisk fire, stirring constantly to prevent burning until it comes to the boil. Withdraw slightly from the fire to prevent boiling over until the mass begins to settle down to boil, which is readily known by the frothiness leaving it. Have ready a teacup of cold water, and with a teaspoon lift out a little syrup and drop into the water. If it lie at the bottom of the teacup so as to lift like very thick paste or putty, it is just right and ready to be removed from the fire. If too much boiled the syrup will be hard and crisp in the water. This can be remedied by adding a little water to the syrup after it has been taken from the fire. Two minutes' boiling is sufficient for the above quantity. The pan should then be placed in cold water to hasten the cooling process. Stir the mass constantly until it begins to get greasy looking, gradually getting whiter and stiffer. It should then be poured into shallow dishes and allowed to cool. The result will be a fine-grained, moist, soft candy, which will be taken readily by the bees. With a little practice anyone may soon become an adept at making it.—AN ENGLISH BEE-KEEPER.

DOUBLING HIVES.

"AN ENGLISH BEE-KEEPER" says that twelve frames 20 inches by $8\frac{1}{2}$ are not so large as the hive I condemn when doubled. Did I say it was? Certainly not. My question at the first was, Is a hive with ten standard frames large enough for the requirements of a prolific queen laying from 3000 to 4000 eggs in the height of the season? Let us look at the hive pure and simple, not only for the summer, but for the whole year. When hives are doubled it cannot be called the produce of one hive, for we have the progeny of two queens—one hive robbed to make another strong.

My contention is that even with the doubling system the queen has not room at the right time. I maintain if the queen has room for her laying powers previous to the honey flow, say 12th of June, we should have hives that need no doubling supposing the season is suitable; besides, with the doubling system we need more hives. I prefer nucleus hives for queen rearing say we want about thirty young queens.

Again, "AN E. B." says "G. H." cannot be serious when he assumes that it was owing to the hive having standard frames in the same apiary as the above—twelve frames 20 inches by $8\frac{1}{2}$ —that no surplus was stored. Yes, I was serious. The experiment was carried out by Mr. Hall of Welham Bridge on several hives in his apiary. Had not the test been with one or two hives there might have been room for doubt. The test was so marked in favour of the large brood nests that Mr. Hall has sold all his hives with ten standard frames, and such has been my experience with large hives. This summer about twenty-five large hives in this district will be tested by more than a hundred hives with standard frames, and all being well the readers of this Journal shall know the result.—GEORGE HOWDENSHERE.

* * All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Propagating *Cryptomeria elegans* (Kenley).—There are two methods. 1, Of cuttings when half ripe, placed in sandy soil and under glass, keeping rather close until rooted. 2, By cuttings of ripe shoots taken with a heel in autumn (October or November), inserting in sandy soil under a hand-light, or inserting in pots and keeping over the winter in cool quarters, but safe from frost, and in spring when a callus has been formed placing in gentle heat, so as to promote the formation of roots. Some, however, prefer to insert the cuttings in August or September under a hand-light, and root entirely under cool treatment.

Soil of Pasture Land (G. F.).—The soil taken 6 inches from the surface is a good rather unctuous loam, and we should consider it to have plenty of body—that is, naturally of considerable fertility, and holding what may be supplied, so that it would not be an expensive soil as regards fertilisers. Two to 3 feet depth of such soil, resting on 4 feet of gravel, and that on clay, would answer well for Grape, Tomato, and Cucumber growing, as it will be naturally well drained. This, however, is matter for consideration on the spot, as also is the aspect and other details that must have due weight in deciding. The turfy top spit we should consider very suitable for Grapes and Cucumbers, but would probably need some opening material, as it seems of a moisture-holding nature, there not being much grit in the sample. There would not be any harm in having an analysis, but it is in most cases only money wasted, as staple and other considerations are of more importance from a practical point of view. Could you not get the opinion of a grower in your locality?

Potatoes Diseased (J. G.).—The Potatoes are infested by the American scab fungus, *Oospora scabies*, a very malignant form, which causes the Potatoes to not only "scab" but turn black and decay, in that respect differing from the English scab, which, though a disfigurement, is evidence of good using quality—i.e., mealiness. We have known the American scab for over twenty years. It is the most virulent in heavy soils or those surcharged with much organic matter, such as very heavy manuring. The best application to the land for it is the lime dressing advised in the reply to "Young Head," with about 10 cwt. per acre of gypsum (sulphate of lime), as the fungus does not like sulphur, besides the dressing corrects the sourness or salinity of the soil. The "sets" should be disinfected before planting, dissolving 1 oz. corrosive sublimate (a virulent poison, which must not be handled in the pure state) by placing it in a wooden (not metal) vessel, and pouring on a gallon of hot water, leaving overnight. In the morning add $6\frac{1}{2}$ gallons of water, or rather have this quantity of water in a wooden vessel, and pour in the 1 gallon solution, allowing to stand four or five hours, stirring several times during that time to insure an even solution. In this immerse the seed Potatoes, washed of dirt, for $1\frac{1}{2}$ hour, then remove and dry. The solution will answer so long as it lasts for more Potatoes. They are easily immersed by placing in a coarse sack. It will not injure the hands when fully diluted, but it must not be taken into the stomach, therefore all treated Potatoes must be planted or destroyed.

Preparing Soil of Tomato House for Planting Vines (J. G. B.).—There is nothing better for mixing with the soil deficient in organic matter than good London manure, which, as you no doubt know, is chiefly that of stables. This, in the case of a light soil, may be used to the extent of one-fifth of the soil moved or employed. As you have 2 feet depth of soil you would require to put on a thickness of 6 inches, then, taking out a trench at one end, turn over the soil and mix the manure with it as evenly as possible, taking small spits and intermixing as well and evenly as practicable. We should do that before adding any fertiliser, letting the soil rest a few days, as you will get a sort of fermentation, though not a perceptible one, that will do much to get the manurial matter diffused. Then you may use a mixture of fish meal, 7 parts; dissolved raw bones, dry and crumbling, $3\frac{1}{2}$ parts; and double sulphate of potash and magnesia, $3\frac{1}{2}$ parts; mix, and apply $\frac{1}{2}$ lb. per square yard. Then turn over the whole border, as a bricklayer's labourer does lime and sand for making mortar, so as to get an even blending of the manure and the other material with the soil. Before planting you may use another $\frac{1}{2}$ lb. of the mixture per square yard, and point this into the soil with an ordinary digging fork, taking small spits and not going deeply. This has given excellent results on soil of a rather light character. The fish meal should be "white fish," and the double sulphate of potash and magnesia guaranteed to contain 48 to 52 per cent. of sulphate of potash and 25 to 30 per cent. of sulphate of magnesia, while the dissolved bones should contain 15 per cent. soluble and 23 per cent. insoluble phosphate.

Insects in Soil (Young Head).—The "insects" are the snake centipede (*Geophilus longicornis*, Leach). It is not an insect, but belongs to the Myriapoda, section Chilopoda, family Scolopendridæ, tribe Geophilidæ. It has a mouth provided with foot jaws, and is carnivorous, harmless, and useful by devouring "springtails," especially *Lipura fimetaria*, which is a vegetable feeder, making holes in Potatoes, and often ruining vegetable crops of all kinds, though it be but one-tenth inch in length. The snake centipede is very common in Britain. It is like a long yellowish or whitish thread, a couple of inches or more in length, with a great number of feet on each side. It has no eyes, but moves along with an undulating and sinuous motion. The female sits upon her eggs, coiling herself round them in a little cell which she makes in the ground, and never leaves them until they are hatched, the period of incubation being a fortnight to three weeks. You could not do better than use the lime, 10 tons per acre in your case would not be too much; the lime being freshly burned, placed in little heaps convenient for spreading, and when fallen, yet whilst hot and floury, spreading. This is best done in a dry time, or when the land is in good working order, as it should be dug in shortly afterwards with a fork, taking small spits so as to incorporate well with the soil. This will be all that is required, as the land having been heavily manured will not need enrichment, and it would be better to avoid the horse manure for a time, or only use it as a mulch in summer for such crops as Peas, Runner Beans, and others to prevent the soil cracking. A moderate use of coal ashes would be useful in rendering the soil more open and better to work.

Fancy Pansy Miss Paterson Diseased (*J. W.*).—The specimen arrived in a shrivelled condition, the moss, instead of having been damp, being as "dry as dust." The leaves are infested with the Violet rust fungus (*Peronospora violæ*), which appears as small rounded brown spots, and causes the leaf to wither and die. It is generally supposed to be induced by keeping the plants too close and moist, which promotes a weakened and soft growth, air being one of the best preventives, with no more water than sufficient to keep the plants fresh. The advice commonly given is "burn all infested plants, and do not use the same soil again for *Violacæ*," is excellent, no doubt. We have found dusting with air-slaked lime, dry and floury, very useful, giving some air constantly, or when not frosty; while the advertised fungicides in powder containing sulphate of copper are efficacious preventives, and prevent the disease spreading.

Basic Slag Phosphate for Vines (*S.*).—It is a good manure for Vine borders, especially when rather strong or close from being heavily dressed with manure or even liquid manure from stables. It is best applied in the autumn, but may be used now, sprinkling half a pound on each square yard and pointing in lightly with a fork, not damaging the roots. It is best applied along with double sulphate of potash and magnesia, using of this 4 ozs. per square yard, and pointing into the soil with the basic cinder phosphate. The foregoing are maximum quantities to use. Ordinarily half quantity suffices, and is better when the roots are near the surface, following in the spring, when the buds begin to swell, with a mixture of bone superphosphate, three parts; powdered saltpetre, one part; and ground gypsum, one part, mixed, using 4 ozs. per square yard, and a similar amount when the Grapes are thinned, washing in moderately.

Preparing Material for Mushroom Beds (*N. O. P.*).—Yes, there is great danger of the material becoming too spent before making up when the manure has lain for some time, and had what may be termed an extra "sweating" before taken in hand by the Mushroom grower. This is a matter upon which growers must exercise judgment, for it is absolutely necessary that the material when made into beds have plenty of "life" in it so as to retain its warmth over a considerable period, slowly decomposing and affording food for the Mushroom mycelium. The plan you propose would be likely to answer in your case better than so much turning at more distant intervals; but the thing is to sweeten the material, and so secure steady and prolonged warmth without overheating in the first instance, for when this dries the material too much the "spawn" cannot run in it, though even that is better than "dead" material, rotten and wet. We have often used manure from stables after removing the long litter, throwing in a heap to get warm, and turning twice at intervals of three or four days, and had excellent crops. Overspent manure is worthless, hence the necessity of exercising discriminative judgment. The evil of over-exhaustion of manure is forcibly pointed out in pp. 25 and 26 of "Mushrooms for the Million," the late Mr. Gibert's remarks being cited:—"To gather droppings, lay them in a shed, dry them, and turn them till there is no strength in them, and then expect Mushrooms, is to me something like madness."

Ivy on Old Plane Tree Stem (*G. B. T.*).—As the old Plane tree is 70 feet high and still vigorous (not decaying materially), the Ivy clinging round its stem would, to some extent, affect the life of the tree, as it does all trees; but, as stated in our reply last week (page 106), is far more prejudicial, for obvious reasons, to young and growing trees than to those arrived at full growth. In the case of developed yet healthy trees Ivy on the stems (not crowding the heads) does not appear to be appreciably injurious, while in the estimation of many persons it adds to their beauty. The matter is one of taste. Some persons would prefer the old Plane tree without the Ivy, when the tree might be expected to live longer. We give the two views to assist you in deciding as to which you would prefer. Ivy on young trees prevents their attaining full development, or as much as they would without it, and causes premature senility. On old trees it hastens their decline, especially when outgrowing them. If you desire to preserve the Plane tree as long as possible cut the Ivy off at the ground, severing its stem or stems, but making sure not to injure the Plane tree, and leave the Ivy to die before withdrawing it from the trunk. Thus, if cut now, leave the Ivy until summer when the Plane tree is in full leaf, then there will neither be danger of its being chilled, as it would if removed, nor of sun-burning if suddenly taken away in summer. The root-stems of the Ivy should also be carefully removed, otherwise they would perhaps grow again.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*D. L.*).—*Eupatorium riparium*. (*G. H. L.*).—1, *Cœlogyne ocellata*; 2, *C. cristata*. (*J. G. R.*).—*Physalis Alkekengi*. (*A. B. C.*).—All the Ferns were dead; the *Cypripedium* is a form of *Harrisianum*. (*N. A.*).—1, *Asplenium bulbiferum*; 2, *Davallia canariensis*; 2, *Nephrolepis exaltata*; 4, *Adiantum capillus Veneris*; 5, *Asplenium nigrum*; 6, *Adiantum trapeziforme*. (*P. C.*).—1, *Cupressus Lawsoniana*; 2, *Abies Douglasi*; 3, *Cryptomeria elegans*; 4, *Thuopsis dolabrata*. (*W. B.*).—Varieties of *Primula sinensis* are florists' flowers that can only be named by comparison.

THE WORLD'S BREAD CORN.

IN these days, when all industries are closely watched, and all results reduced to figures, it is interesting and not a little instructive to look back for a few years on the development and growth of the corn cultivation.

It is a fact we are likely to lose sight of sometimes that till lately a vast population, numbering millions, fed on bread stuffs made of other than Wheat flour, Rye, Barley, and the like. They did not eat these inferior grains from choice but of necessity, and no sooner did Wheat flour become both cheap and plentiful than

they were ready consumers of the better quality. That they will ever want to return to their old diet is hardly probable; the tendency of human nature is to crave for more luxuries and comforts.

We English farmers thirty years ago, secure in our position as Wheat growers, never dreamed of the troubles the future had in store for us. If indeed we knew we hardly realised what immense tracts of land were opening out in Canada and the States. We never reckoned with the small South American State of Argentina. Indeed it was doubtful we could at first sight have found it on the map.

Alas! poverty has acquainted us with strange bedfellows, and we have been learning a very severe lesson. Low prices we had seen and met, but depression caused thereby passed till 1879, when depression came, not as a passing guest, but to stay apparently permanently. In 1878 Wheat dropped to 46s. 5d. per quarter, 10s. 4d. less than the preceding year. In 1879 43s. 10d. was the price per quarter; from 1880 to 1882 it rose to 45s. 4d.; in 1883 the average was 41s. 7d.; in 1894 it reached the lowest average of the century—namely, 22s. 10d. "The mean price," says Mr. Bear, "of the last six years is 44½ per cent. lower than that of the 'seventies.'"

Now for the reason of this great drop in price; it is not far to seek—greater acreage under Wheat and some phenomenal crops. In one country—viz., the United States—there was an increase of nearly 19,000,000 acres in the ten years ending 1880. During the "eighties" the U.S. did not develop their Wheat-growing area; but we find the harvests of the decade ending 1890 were better than those of the former decade.

There seemed a chance in 1891 the Wheat prices would rise, as Russia was threatened with famine, and the French crop was deficient by at least one-third. Rye, too, on which so many of the Russian peasants subsist, was almost a failure, not only in Russia, but in other Rye-growing countries. But this shortness of supply only had the effect of sending up the English price 3s. 2d. per quarter. This only lasted about twenty-eight days, then down it went to 36s. 6d. Why? The American crop was the largest hitherto produced. They exported considerably more than double the average of the preceding four years. Argentina exported 15,000,000 bushels. India sent to Europe nearly double what she had ever sent before, and Canada supplied other 12,000,000 bushels.

Although Russia and France were in such sorry plight, the one famine stricken, the other with a crop much below the average, the world's Wheat crop was larger than had ever formerly been known.

In 1892 the price fell to 25s. 9d.; this was owing to the still greater crop of that year. In 1893 there was a further increase in the Wheat supply. The United States fell off a little, but Argentina came to the front with a grand total of 57,000,000 bushels. The European harvest, too, was a great one, India good, Australia over an average; but it was destined that we should see in 1894 the greatest Wheat crop on record.

The United States produced over an average, Argentina now reached the grand total of 79,000,000 bushels, there was a record crop in Europe, India had an average Wheat harvest, Canada a good crop, Australia a moderate one. All this combined to produce an embarrassing supply of Wheat, coming, as it did, after four good years, so that in September of that year we had in hand 19,000,000 quarters, and added to that the largest crop on record. Down dropped prices again, absolutely touching the low figures of 17s. 6d. per quarter. As Maize was very dear, much of this Wheat was consumed by stock in the States, the quantity being estimated at 100,000,000 bushels.

Wet weather had spoilt a good deal of the grand European crop, and so a tremendous proportion was here also consumed by stock; and, added to this (as we remarked earlier), the Rye-eating nations took to Wheat flour instead. The crop of 1895 was a good

one, though less than that of 1894, and prices rose in December to 25s. per quarter.

Although early in 1896 there were signs of a coming scarcity in the Wheat crop, prices remained low, and continued to fall till the third week in August. Even when statistics proved that the supply was from 18,000,000 to 20,000,000 quarters short of 1895, there was no rise in the markets till August 24th. On October 19th there was in Mark Lane an advance of 3s. to 5s. per quarter. This was in a measure owing to the fact of the disappointing yields in the States and Canada, a deficiency of 5,000,000 quarters on the Russian crop, severe drought in Australia, and impending famine in India.

What the price of Wheat will be before next harvest is a secret of the future. A good seed time this spring will tempt Argentina and Australasia to increase their acreage. We have at present a very short supply, and that in the face of an increasing population. Dare we hope once more to see Wheat growing assume its old place in the annals of farming, and be again a remunerative crop? The cheap loaf is all very well, but it may be too cheap, and while it saves the pockets of some, means ruin to others.

WORK ON THE HOME FARM.

Another week has passed away, we are well into February, and farm work is almost at a standstill. True we can realise last year's crops, and by so doing we are keeping markets in a congested state, and preventing any rise in price, but preparation for another harvest is impossible. All we can do is to wait patiently until the clerk of the weather is in a more genial humour. Meanwhile we can gather a little comfort from the fact that the frost is doing much good to the soil, and that an enormous amount of water has drained off during the last two weeks.

The consumption of food by cattle is now very heavy, the supply being anything but excessive. Straw has not stood as much eating as usual; this is generally the case after a dry summer when the straw is short, there always seems to be a larger proportion of pulse and waste. Fortunately Swedes are taking up heavy, and are holding out well. We cut up all the straw, and give pulped Swedes with it in about equal proportions; this is a much larger proportion of root than we usually can afford for the holding stock, but they must have it to eke out the straw.

Very few cattle are being fed off in some districts, and we are looking for a rise in price of beef shortly. Let us hope the Americans will not flood us with meat and spoil the prospect. There is a better feeling in the trade already, and the same may be said of pork, both fat and store pigs being very decidedly dearer. Ewe mutton is again bad to sell, and we cannot wonder at it. We do not own to a partiality for it ourselves, and it is not surprising that townspeople have similar tastes. Even the Oliver Twist of to-day is not snubbed if he complains that the work-house mutton is tough or too fat. He never has any need nowadays to ask for more, for the Local Government Board insist on his having more than he can eat; but this is good for the meat trade if only the farmer were not the chief payer of the bill.

Breeding mares require great attention now. They must not be put in shafts on any account, and heavy pulling of any kind is bad for them; at the same time regular light work is most desirable.

REMARKS.

- 31st.—Dull all day, and dark about 1 P.M.
1st.—Rain in small hours; slight snow early; dull drizzly day, with high fog at 1 P.M., and slight fog in evening; rain at night.
2nd.—Almost continuous rain till 2 P.M., and from 5.30 P.M., changing to snow about 8 P.M., and continuing to midnight.
3rd.—Overcast early, foggy from 9.30 A.M., and rainy from noon to midnight.
4th.—Mild and dull day; rain from 7 P.M. to 9 P.M.
5th.—Almost incessant rain from 0 A.M. to 9 P.M., and dark and foggy in afternoon.
6th.—Fair day, with a little sun in morning.
A week of average temperature, and of very heavy rain.—G. J. SYMONS.

NOW READY.

BARR'S SEED GUIDE

For 1897.

Barr's Seed Guide is full of practical hints, and is invaluable to Gardeners, Amateurs, and Exhibitors.

 FREE TO INTENDING PURCHASERS.

VEGETABLE SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Select List of the Best Vegetable Seeds for securing a supply of Vegetables "the year round."

FLOWER SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Choice List of the best Seeds for the Flower Garden and Greenhouse.

ALL SEEDS CARRIAGE PAID ON RECEIPT OF REMITTANCE

We guarantee all our Seeds to be of the finest selected strains, and of highest growing quality.

BARR & SONS

12 & 13, King Street, Covent Garden, LONDON.

ANT. ROOZEN & SON'S

CHOICE

VEGETABLE & FLOWER Seeds

FOR PRESENT SOWING,
AND

BULBS AND PLANTS

FOR SPRING PLANTING.

COLLECTIONS OF VEGETABLE AND FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM, HOLLAND, or to our General Agents,

Messrs. MERTENS & CO.,

3 CROSS LANE LONDON, E.C.

No. 889.—VOL. XXXIV., THIRD SERIES.

Barter's TESTED SEEDS.

A FEW MORE
New and Improved Vegetables.

CARTERS' OUTDOOR TOMATO.

The very best for open-air cultivation we know of. Should be grown by everybody.

In Sealed Packets, price 2/6 each, post free.

CARTERS' LEVIATHAN BROAD BEAN.

The longest-podded Broad Bean grown; fine for exhibition, and one of the best for cooking purposes. We have seen pods 21 inches long.

In Sealed Packets, price 1s. 9d. per pint; 3s. per quart, post free.

CARTERS' RED ELEPHANT CARROT.

A veritable giant, both in length and rotundity. Specimens exhibited at our establishment measured 2½ feet in length.

In Sealed Packets, price 1/6 each, post free.

CARTERS' EXTRA EARLY AUTUMN GIANT CAULIFLOWER.

This magnificent variety is more dwarf, considerably earlier, and altogether better than the old form. Grown in large quantities for Covent Garden Market.

In Sealed Packets, price 2s. each, post free.

CARTERS' SOLID IVORY CELERY.

Still maintains its position as one of the best white Celeries in cultivation. A customer writes:—"It was the only Celery we found good at the break-up of the intense frost."

In Sealed Packets, price 1/6 each, post free.

CARTERS' MODEL CUCUMBER.

Many so-called new Cucumbers are brought forward every season, but little is heard of them afterwards. This fine variety still maintains its position as the handsomest in shape, the best in flavour, and the finest in cultivation.

In Sealed Packets, price 2/6 and 3/6 each, post free.

CARTERS' RECORD ONION.

The largest Onion grown. A customer writes:—"I cleared the whole roost in the Onion competition with 'Record.'" We have seen a specimen bulb that weighed 4½ lb.

In Sealed Packets, price 2/- each, post free.

THE CARTER SPINACH.

Mr. A. PETTIGREW, Head Gardener to the Earl of Bute, writes:—"The best Spinach in cultivation; quite distinct from all others." Award of Merit, R.H.S. trials, 1895.

In Sealed Packets, price 2/6 per pint; 6d. per oz., post free.

Illustrated CATALOGUE, Gratis and Post Free.

Journal of Horticulture.

THURSDAY, FEBRUARY 18, 1897.

CUCUMBER AND TOMATO TROUBLES.

WHEN the ordinary human creature gets "out of sorts" he is apt to read up all medical information bearing upon his particular form of complaint. What is the result? Simply confusion. Afflicted persons are advised to abstain from nearly everything that goes to make life enjoyable, and the other remedies can be reckoned up by the score. It is much the same with our troubles in the plant, and more especially the fruit-growing line. I have had what I feel disposed to assert more than my share of these, and as a matter of course consulted the oracles on all possible occasions. Result—nervousness, prostration, and finally recklessness. These experts render good service in drawing attention to and diagnosing the various diseases they make a study of, and occasionally have the good fortune to suggest a remedy for some of them. Unfortunately the majority of these specialists are strong in theory, but not practical. Some of their suggestions are quite unworkable and ridiculous, and if we heeded one-half of what they advise, the remedies would be worse than the diseases. This I have proved to my cost.

Our good friend Mr. Abbey I do not class with those who are theoretically strong only. It is true he revels in many and sundry scientific phrases, which practical men abominate; but he is one of our most experienced gardeners, and what comes from his pen ought to be treated with respect. I believe I have to thank him for one good remedy, and also for being nearly frightened out of practices which I have since returned to, and found to be the salvation of certain crops. My time is so fully occupied that I do not propose to follow Mr. Abbey through his various communications on the subjects of Cucumber and Tomato diseases, my intention being to convey in a plain manner my own experience during the past few years, commencing with Cucumbers.

That great bugbear the eelworm has been much in evidence of late years; but is no new trouble. It has always been with us; but the

serious failures with Cucumbers among market growers have brought the eelworm into prominence. If my experience is any criterion we have largely to thank ourselves for the mischief that befalls our plants. Correct methods of cultivation I believe to be the best preventives. On the score of economy in construction market growers have been tempted to grow Cucumbers in houses not sufficiently well heated, bottom-heat pipes in particular being conspicuous by their absence. The plants may grow remarkably well for a time in little mounds of compost resting on the solid ground; but once let the treatment be of a nature to militate against good surface-root action and it will be a case of good-bye to the plants. When plants in full bearing order fail by the dozen or score eelworm or some other dire complaint is credited with the cause. Let experts once get hold of the stems and roots and they are certain to find something very bad with a high-sounding name. The enemies they see are of course there, and the savants make the most of them and—themselves; but the pests are more the effect than the cause of the collapse after all.

Private gardeners frequently start their Cucumber plants on hotbeds of manure or manure and leaves. While the fermentation continues the plants are in a happy thrifty state. Unfortunately heat and moisture soon lead to the heating material becoming rotten, and then, if there are no bottom-heat pipes, it is not long before some or all of the plants commence flagging seriously in the sunshine. The eelworm is then in the ascendant. It has been invited, and has accepted the invitation. The same thing happens when heavy masses of rich retentive soil are provided for the plants to root in, or worse still, banked heavily over the old soil by way of a top-dressing—sometimes in the case of plants grown in frames when the bottom heat fails.

The other extreme—too much heat and too little moisture at the roots—must also end fatally to Cucumber plants, especially as treated by some market growers who have not had sufficient experience in the “express system.” It would really appear that the eelworms are present in most soils that may be prepared for Cucumbers, and are only waiting for a check to the growth to be given before asserting their destructive power. If by good culture healthy root action is sustained it is not much harm that this minute pest can work. This dictum may not commend itself to some of my readers, but first let them see whether the treatment that failed in their case corresponds in the more important points with what I am about to advance as being nearly or quite the correct practice.

Cucumbers are essentially heat-loving plants, therefore provide sufficient fire heat to maintain a temperature that seldom if ever falls below 65° during the night, with an increase of 5° to 10° by day from fire heat in the early spring months, while the bottom heat ought to be nearly or quite as strong. Instead of planting healthy young plants on the top of a great mass of soil, insert them deeply, yet carefully, burying 2 inches of the stem in about a peck of soil previously well warmed through. What kind of compost ought to be used is a question that would quickly occur were I to omit all description of what answers well with me. In anticipation I reply, Nothing very particular. If “good brown fibrous loam,” which we hear so much about, and which so few of us can obtain, be available, by all means use it, breaking it up roughly, adding only a little manure. Some growers stack their turves with farm-yard or stable manure sandwiched between. They may do so for aught that I care, but give me fresh soil stacked only long enough to kill the grass, and nearly fresh manure.

As it happens, we can only procure turf of a black, spongy, water-holding nature, and much prefer sandy medium loam, or a natural blend of clay and loam in equal parts, without any fibre in it, and as “poor as a crow.” To two parts of this are added one part of horse droppings, prepared as for a Mushroom bed, with a liberal addition of wood ashes and scorched soil. This is good enough to plant in, and with a “peppering” of soot good enough for the subsequent top-dressings. Doubtless eelworms are introduced with

either the manure or soil, but it depends on ourselves whether they shall prosper or not. What we have to remember is that Cucumber plants growing in strong heat must evaporate large quantities of moisture, and unless roots are constantly and rapidly increasing, of what avail are the heavy supplies of water? On the other hand, sometimes the cultivator forgets to supply abundance of water to the roots, or not enough to keep them alive, let alone meet the requirements of the foliage, then the eelworms are happy.

Cucumber roots delight in a moist warm atmosphere, and should be kept active well within the reach of it. That is a good reason for starting with a small mound of porous soil. As fast as the roots take possession of the old soil top-dress lightly with some fresh compost, once a week not being too often to give these light surfacings. If the soil is not unduly exposed to the sunshine nor allowed to become too dry the whole mass is soon taken possession of by a network of root fibres, and eelworms make no progress. During hot weather once a day is not often enough to give water, but the plants should have it twice, if not three times, also keeping the atmosphere nearly saturated. Heavily cropped plants should be assisted with clear soot water, varied with nitrate of soda applied at the rate of half an ounce dissolved in one gallon of water. We use it ready dissolved, measuring the liquid that is added to each can of water with a handy tin ladle. Anything that clogs the surface of the soil, including thick soot water, does more harm than good.

Many gardeners pride themselves in keeping their plants in a healthy bearing state for the greater part of the season. It would be less trouble and more satisfactory in the end if they adopted the market growers’ plan of getting all they can out of their plants in a few weeks, and then start afresh. A succession could easily be kept up by commencing with one-third less plants than formerly, making successional sowings and plantings at intervals of about a month. Plant at 2 feet apart, run the plants up quickly, crop heavily from the lateral growths, leaving no fruit on the main stems, and if grown quickly the produce will be of superior quality to that usually obtained from worn-out old plants. There is not much time for eelworms to do much mischief under that system.

Now we are come to the phenyle business. Little’s soluble phenyle was first suggested in these pages (by Mr. Abbey, I believe) as a possible remedy for eelworm. After giving it a fair trial I can honestly affirm that it does check the progress of eelworms, and I keep a tin or small drum of it always at hand in case it is wanted. When important work has to be entrusted to careless youths it is apt to be scamped. Our Cucumbers sometimes apparently get enough water, but only the surface is moistened while the soil underneath may be as dry as powder. That is the eelworms’ opportunity. Anyway, whenever any of our plants commence to flag from no apparent cause an examination of the roots usually discloses the fact that eelworms have gained the upper hand, and knobs on the roots are plentiful. Thoroughly moistening with clear water is not enough, but if followed by a dose of phenyle applied at the rate of 1 pint to 18 or 20 gallons of water, the majority, if not all of the affected plants, will regain their rigidity, and quickly make good growth both below and above the soil. We do not wait till the plants are half dead before applying phenyle to the roots, but commence with it on the least signs of flagging.

Last season, in order to thoroughly test the value of phenyle, we used the soil in a Cucumber house a second time, well knowing that eelworms were numerous in it. It was given a soaking of phenyle rather stronger than I have recommended for the growing plants, and “livened up” with a little fresh soil and manure. Considering the lateness of the season, the result was most satisfactory, the phenyle having done good service, both as a manure and insecticide. This is enough at once, Tomatoes another time.—W. IGGULDEN.

ACACIA CULTRIFORMIS.

SEVERAL of the Australian Acacias are known in gardens, as they are useful and distinct plants for greenhouses, and mostly flower profusely in the spring months. One of the species—namely, *Acacia cultriformis* (fig. 30)—is peculiarly distinct from most of those with which most growers are familiar. It has flat, somewhat triangular, silvery white phyllodes, and racemes of small, globular, bright yellow flower heads freely produced along the branches, and when a good-sized specimen is in flower it has a very remarkable appearance. In pots, plants of moderate size flower readily, requiring a compost of peat and sand, with the same care in the supply of water as is needed for hardwooded plants. During the spring months some of the florists' shops display bunches of *Acacia cultriformis* apparently obtained, with others now in great demand, from continental growers.—F. W. W.

OUR HARDY PLANT BORDER.

(Continued from page 555, last vol.)

WALLFLOWERS.

THE work of preparing the border, as regards digging and allotting sites for plants requiring particular soil or special treatment, having been accomplished, as already described, it became necessary to arrange for the planting. The situation being both cold and damp necessarily restricted the selection of plants greatly, as in order to avoid the annoyance and loss that would result from the continual death of choice or delicate plants, only those that possessed the hardiest constitutions could be chosen. At the same time it was desired to secure as good a floral effect as possible, and the best means of assisting this object seemed to be afforded by raising seedlings of some of the more effective annuals or biennials. First on the list were placed Wallflowers, chiefly because they are great favourites, but also for the reason that they could be easily and quickly raised, and an extensive bright display could be insured the following season. To this useful plant therefore a few remarks will be devoted in the present letter.

Perhaps few better instances are afforded of the extreme range of conditions under which cultivated plants will thrive, as compared with their wild state, than we have in the Wallflower. The *Cheiranthus Cheiri* of botanists is not only a native of England, but is also found in many districts of Europe, frequently on old walls and in similar situations where there is comparatively little nourishment to support vegetable life, and which seem more adapted for such succulent plants as *Sedums* and *Sempervivums* than for a plant of the Wallflower habit. Some years ago a garden under our charge was bounded on one side by an extremely old wall of considerable thickness, and this was the abode of many interesting little native plants; but most conspicuous amongst them were the Wallflowers, which have during a long period held a position there, every season producing abundance of their bright yellow flowers, followed by seed from which an annual supply of young plants keep up a constant succession. Many of these when in flower formed miniature bushes 4 to 6 inches high, symmetrical little models, every branch terminating in numerous small flowers rarely exceeding half an inch in diameter.

These are the kind of plants found as wild representatives of the Wallflower, yet under cultivation we have had plants over 2 feet in diameter, bearing hundreds of flowers 1½ to 2 inches in diameter. They will grow and flower, too, in almost every situation, except that swampy or much shaded; but though the extremes are not desirable, yet a moderately moist but well drained soil is preferable to a dry one, notwithstanding the fact that the Wallflower in a wild state is almost invariably found in dry, poor situations. Wallflowers can be greatly improved by the judicious application of manures, especially artificial manures, as we have fully proved, but the time at which the stimulants are applied, and the condition of the plants when the manurial aid is supplied, if this is done after the plants are transplanted from the seed bed, are of great importance. Apart from the use of manures altogether, however, the method of raising the plants and the growth secured before the winter have a considerable bearing upon their ultimate success.

The time of sowing is an important matter, and though we have sown every month from March to August, there is one time which in the majority of seasons has given much the best results, and this is the first week in May. In warmer districts April, or even March, will be suitable, but it is not advantageous to give the plants too long a season, all that is required is a well developed but sturdy growth that will not suffer during the winter. Still, if not sown sufficiently early for the seedlings to have progressed beyond the early stage before the heat of summer overtakes them, they will be seriously and often permanently checked for the whole season. This is precisely what must be avoided as far as possible,

as, like many other plants raised from seed, the Wallflower is impatient of any prolonged check in its young state.

The seed bed should be well prepared by digging and pulverising the soil, but it must be moderately firm; and we prefer sowing the seed thinly in drills 6 inches apart to sowing broadcast in a bed. Various stimulants have been tried, to ascertain whether any advantage is derived from providing some special food in the soil ready for the seedlings to appropriate to their immediate advantage, but the only benefit observed was in one season, when owing to unfavourable weather a late sowing had to be made. On that occasion half the seed bed received a very slight dressing of nitrate of soda, at the rate of about a quarter of an ounce to the square yard, the result being that the seedlings on the dressed

FIG. 30.—ACACIA CULTRIFORMIS.

portion of ground made much more rapid progress than the others, in fact they were very little behind those raised two months earlier in the ordinary way. Beyond this no special advantage has occurred from manures in the seed bed—indeed, there is a danger of having too much growth before the young plants are thinned.

The question of transplanting is an important one, and a comparison has been made of the effects produced by the following methods of treatment:—1st, Sowing the seed where the plants were to remain, and thinning to the required distances; 2nd, Transplanting direct from the seed bed to the position where the plants are to flower; and 3rd, Transplanting from the seed bed, and then again subsequently to their permanent quarters. The last necessarily means considerably more expenditure in time and labour, and therefore under some circumstances would be impracticable, but experience has in my case proved that this system gives much the best results. The chief difficulty is to secure suitable weather conditions at the first time of transplanting, which is preferably done within a month from the time of sowing if the seedlings have made sufficient progress. This brings it to the first

or second week in June if the sowing is made early in May as advised, and should the weather prove hot and dry the plants are liable to suffer very much. It is therefore sometimes advisable to wait a week or more to endeavour to secure the right opportunity, and in any case a thorough supply of water, both before and after planting, will be needed.—A COUNTRYMAN.

(To be continued.)

PRECEPT AND PRACTICE.

(Continued from page 89.)

CONTINUING our brief introduction to nomenclature, names denoting colour present probably the least difficulty to a beginner, and once grasped are easily retained. Alba, white; aurea, golden; viridis, green; cyanus, bright blue; rosea, pale red; purpurea, purple, are duly represented by *Anemone japonica alba*, *Valeriana Phu aurea*, *Ixia viridiflora* (probably the most telling example we have of a green flower), *Centaurea cyanus*, *Primula rosea*, and *Justicia purpurea*. From the principal colours spring many equally expressive terms, which our young student cannot fail to become acquainted with according to his desire for knowledge and steady application to acquire it. Variegation and marking may here be coupled with colour. Variegatus, or variegata, is a name speaking for itself, whilst guttatus, spotted; punctatus, dotted; pictus, painted; marginatus, edged; and vittatus, striped, are equally adapted for our purpose, and need not further detain.

Habit is revealed by such names as procumbens, procumbent—spreading on the surface; erecta, erect; dependens, hanging; prostratus, prostrate; spiralis, spiral; plicata, plaited—folded like a fan; all of which can be identified respectively by observing the manner of growth of *Gaultheria procumbens*, *Cupressus erecta*, *viridis*, *Cantua dependens*, *Dianthus prostratus*, *Vallisneria spiralis*, and *Panicum plicatum*. The native homes of many of our plants are constantly before us in such names as capensis, the Cape; sinensis (or chinensis), China; indica, India; japonica, Japan; brasiliensis, Brazil; persica, Persia; with a host of others fairly easy of recognition. Those names which have now been noticed are samples of what may be termed descriptive names—that is, describing in some way or another some characteristic of the plant they are appended to. A passing notice of names not included in the above category, which for our purpose we will call generally distinctive, may conclude this subject. These require but little explanation, the bulk of them being names of honour resolving themselves into two classes, the first of which, ending in *i* or *ii* (the Latin genitive singular), as Veitchi, Douglasii, Burbidgei, have been awarded to particular varieties in recognition of the discoverer, introducer, or raiser. Purely complimentary names are (or should be) distinguished by the qualifying termination of anus, ana, or anum, as *Sanderianus*, *Devonianus*, *Lowianum*.

There is, I believe, some little confusion of ideas still existing relative to these qualifying terminations of names of honour. The simple rules I have endeavoured to lay down are the grains picked up when the argument was thrashed out in a potting shed some thirty years ago. Since then I have found the correctness of the principle endorsed by a very high authority upon the matter. Respecting the use or omission of capital letters in writing these distinctive or descriptive names, the matter whilst being of some importance is one upon which even "doctors differ." We can therefore only follow such customs with their variations as are to be found in carefully edited plant literature. Some trade catalogues leave little to be desired in plant nomenclature, but many are in that respect faulty. The *Index Kewensis* ought to be the standard authority, but it has been weakened by the different renderings of certain names in subsequent "Handbooks" from the Royal Establishment. Once more I would beg young readers to understand that these explanatory remarks upon nomenclature are but the desultory digging up of a few old Latin roots in that vast field through which many pass unheeding the rich stores buried beneath an apparently hard crust; but what a pleasure it is to find such revelations of character to enhance the value of a world of beauty.

Greek roots are occasionally to be met with. Chryso, yellow; chloro, green; and erythro, red, for example. Reference to standard works and personal observation will not fail to detect their right of being. The Latin tongue being the foundation of speech in France, Spain, and Italy one cannot proceed far without noticing the connecting link between those languages and the great importance it has in its bearing upon our subject. Owing to a series of short papers entitled "Bothiana" having appeared so recently as 1895, vol. xxx., commencing on page 330, it is scarcely necessary to repeat the several hints there laid down for self-tuition in the bothy or prior to entering it, but I would ask our young student to turn back to them if he can conveniently do so, and assimilate in the morals there conveyed.

To attempt any course of self-tuition in a desultory manner is simply out of the question with those who wish to reap the highest possible benefit; hence in spite of what has been previously promulgated, I will venture to express a few thoughts upon this matter. Looking back on early life, and recalling the memory of one of the stiffest battles I ever fought with myself, I cannot but sympathise with those boys who are fighting now the same battle, and fighting it, as practically they must, alone. Over this subject hangs the crisis by which we are henceforth to be governed by inclination or guided by reason. Supposing some young reader has now the moral courage to commence a series of apparently well planned lessons with all seriousness of purpose, what are the unseen dangers so fatal to many who thus begin? It may be that a lad has fashioned his plans upon a mistaken judgment of their ultimate utility, and after starting a dawning consciousness that such is the case tempts him to make a fresh start in another direction; this, in its turn, may, from a similar cause, entail further change, a state of things which may be prolonged indefinitely. Such is not of uncommon occurrence in life, but most disastrous.

I have said somewhere before, and must repeat it, that a vacillating policy is of all policies the worst. Our young student cannot contemplate too seriously the lines of self-tuition he is about to lay down, and he may also endeavour to form a fair estimate of the leisure he is likely to command, with an approximate filling in. For obvious reasons this might be done on a sliding scale, in fact should be, according to season and its contingent calls of duty upon the leisure hour; but at starting this sliding scale must entail a certain danger of slipping to our youngest travellers, therefore I would rather see them adopting some simple course of reading, writing, drawing, and what not, for the first twelve months. Having laid down your rules of self-instruction for this period, let them be unto you as the laws of the Medes and Persians till the term has expired. If on the expiration of one month, or two, or three, the conviction is forced upon your mind that some little mistake has been made, that it would be better to change a subject, and "zigzag" in something else, do not give way, I beseech you, unless from circumstances over which you have no control. I would rather see you pursue a somewhat mistaken course of self-tuition for twelve months, for the loss may be but small, the gain infinite, possibly affecting the whole course of life.

Self-imposed tasks are seldom easy ones at this age. Can you lay down a year's course of training for the leisure hours and keep the track with unflagging zeal? If so you are more than conqueror. Probably not more than one in a dozen can accomplish this; but each should try to be that one. Its importance may not be immediately recognised, but it is the secret of success. Only those who have fought such battles and gained them know the subtlety of the unseen enemy who is overcome. Granted this most desirable state of things the rest is comparatively easy, for our labours are now metamorphosed into a most delightful recreation worthily crowning the day's work. A conscientiously kept diary is, I think, an invaluable aid, the act of writing alone being particularly helpful to engrave things upon the memory. A large folio office diary 13 by 9 inches, interleaved with blotting paper, three days on a page, is probably the best we have at present for the purpose. The blotting pages I invariably use for pencilling down any surplus memoranda. Used in the ordinary way as a blotter I think disfigures the book; perhaps you may think so too, and keep a sheet of ordinary blotting paper for the purpose. In any case let your diary be a model of cleanliness and neatness; there is no pride or pleasure taken in a smeared or smudged volume. These small things are the indices of character, and have not been beneath the notice of that great satirical writer Pope, who said, "E'en copious Dryden wanted or forgot, the greatest art—the art to blot."

As we receive so many good things from Fleet Street it may be that some day we shall have a "Gardeners' Diary" on the same lines as the office diary mentioned, with the substitution of relevant memoranda for that better suited to commercial men. Such would come as a boon and blessing to most gardeners, especially young ones. I venture to think that a diary with fac-simile covers of the bound volumes of the *Journal of Horticulture*, and so arranged as to be worthy of bearing the same motto, "For Gardening and Gardeners," would be gladly availed of by most members of our large family, and even at a necessarily increased cost would, indeed, be worthy of ourselves and our shelves.

However; Boys! do not wait for the good things coming. Remember a diary is all but indispensable. Make the best use of the best to hand, in which set down all your memoranda decently and in order. We, of all men, must conform to heaven's first law in all phases of our life and work, however trivial they may appear, carrying those grand precepts into our practice which have ruled since "Yonder spheres sublime, pealed their first notes to sound the march of time."—AN OLD BOY.

(To be continued.)

GROWING TUBEROUS BEGONIAS.

STARTING THE TUBERS.

As a rule the tubers of double and single tuberous-rooted Begonias do not commence growth early without some gentle stimulation. They should not be forced or hurried into starting by an undue amount of heat and moisture. A constant and regularly moist bottom heat of 55° to 60° is a suitable temperature for promoting growth. Heat and moisture judiciously applied and managed during the time preceding the appearance of shoots, as well as for some time afterwards, is most helpful in securing a few early flowering plants of both double and single varieties for the decoration of the greenhouse and conservatory.

The main bulk of the tubers may be allowed to commence their growth in a more natural way. Afford a portion the benefit of a warm corner in a greenhouse or vinery. The rest may be temporarily placed in boxes of light sandy soil in a frame after danger of frost is past, and in due time sturdy young shoots will be produced, probably much more vigorous than those induced to push under the pressure of artificial heat. The frame treatment is without doubt the best for plants intended for bedding purposes. When they are thus wanted for outdoor purposes the tubers should be allowed sufficient room, so that the shoots and leaves may not be crowded at the first. Much depends on securing vigorous, compact plants, exhibiting no appearance of the growths being unduly accelerated. Frame treatment insures this, and the plants can be transferred direct from the boxes to the beds in the early part of June. Instead of placing in boxes the tubers might be planted in a spent hotbed in light, rich soil in April, keeping the lights closed until growth has started freely.

The method of starting the tubers into growth for an early display of bloom is simple and usually effective. Instead of placing the tubers in soil, which is liable to become sour before roots can enter it, I find cocoa-nut fibre refuse mixed with silver sand to be an excellent medium. It is open and readily diffuses warmth, retaining no superfluous moisture whereby the tubers or young rootlets can be injured. The young roots which issue from the tubers easily penetrate the particles and find the genial warmth as well as the moisture they delight in. That they like this substance is evidenced by the rapidity with which the roots multiply in it, forming quite large tufts or wigs of rootlets.

POTTING AND AFTER TREATMENT.

Though the fibre and sand is useful for the earliest roots to penetrate, yet the continued and successful growth could not exist upon the limited food supply the mixture affords, hence it is desirable that more substantial fare should be provided. A suitable compost for Begonias consists of well-decayed turfy loam four parts, leaf soil two parts, decomposed manure one part, and half a part. To a bushel of this mixture add a pound of artificial manure of a general character. By allowing the compost to lie a short time, frequently turning it, some of the elements in the manure will become diffused through the bulk, and a more complete intermingling of the whole ingredients secured.

In potting the growing tubers larger pots than necessary ought not to be employed. For producing the earliest plants the tubers should not by any means be overpotted. When it is desirable to shift the plants again the smallest sized pots in which the tubers can be accommodated should first be used. It is not advisable to cramp the tufts of healthy rootlets proceeding from tubers which have commenced growth into pots which will not admit of their being reasonably spread out. Some tubers only require once potting. Fair-sized examples furnished well with rootlets usually need 5, 6, or 7-inch pots, in which they may be allowed to flower. For the smaller tubers pots must be employed most suitable to their vigour as indicated by the strength or weakness of the growths and the freedom or otherwise of the rootlets.

Clean pots are indispensable. If the plants remain in them permanently for the season there is every need for sweetness and cleanliness. Should they only temporarily remain in the pots first used, subsequently transferring to others of larger size, the inside of the pots must be clean, in order that the roots may turn out easily and not adhere to the dirt on the pots, as they do when they are not properly washed. This is a simple matter, but one of importance. Arrange efficient drainage in the pots, and the tubers may be level with the surface of the soil when the potting is finished. The compost must be worked among the roots carefully, so that they are distributed well.

The potting material being moist when used, only slight sprinklings of water are required for a few days until the roots commence working. Subsequently more liberal supplies may be afforded, judging correctly the quantity needed at each application according to the activity of growth and the loss sustained by evaporation. Dry hot weather and free growth make large

demands upon the available moisture. A fairly moist atmosphere with a buoyant warmth of about 60° seems to suit the Begonias during the early stages of growth. Abundance of light is essential to modify the growth, but hot, direct sunshine may not always prove beneficial, and a light shade then becomes necessary. As the natural warmth of the season increases a free circulation of air is of the greatest importance. It insures the continuance of a short-jointed robust character of growth in the stems and a rich healthy tone of colour in the foliage. Flowers will then be produced freely and in the highest state of excellence the plants are capable of. Checks to growth, from any cause whatsoever, must be avoided when Begonias are on the point of flowering. This is the real cause of flowers falling before they open and buds dropping prematurely.

Mild stimulants, occasionally given, are of assistance to growth and the promotion of continued free flowering throughout the season. They are not required, however, until the pots are full of roots. Deficiently rooted plants do not experience any benefit from liquid manure. The applications tend to sour the soil, because the absorbing power of weak or few roots is not strong enough to abstract the supply quickly. Weak soot water may be used alternating with solutions prepared from cow, sheep, or horse manure used in a clear diluted state. Slight top-dressings of any of the advertised chemical manures, washing in with water, are excellent, or the manures can be dissolved in the water supplied.—E. D. S.

HARDY FLOWER NOTES.

STRIVE as we may it is difficult to write cheerily of our outdoor flowers when they are deep under the snow. We were in hope that other mild seasons might be repeated this year; that we might enjoy the earliest flowers without interruption from the great powers of the north. For a time it was but guerilla warfare they waged. Short-lived frosts, sprinklings of snow, cold winds. These only lasted a time, and were met, not unsuccessfully, by the gentler influences with which the hand of Nature calls her children from their sleep. But now—when January is nearly gone—the armies of King Frost are almost in possession of the land; their fierce beleaguering only modified by the gentler accompaniment of their ally the snow. All through the night it has fallen, and still it comes. It is the deepest fall of the season. The golden Winter Aconite cups are warm and snug under it. Its counterparts in purity, the Snowdrops, have bent to the ground beneath its weight, and are long out of sight. The Crocuses are shut off from our eyes by an impenetrable screen, and the other flowers which have sought to dare the winter's wrath gladden us no more. Yet we know they are there, and we shall not forget them as they were before they disappeared from our sight.

First must come the Snowdrops, many of which have been in bloom. Varied are they—not in colour perhaps, but in size and form. The common Snowdrop looks small and slender beside Elwes', one of the best forms of Imperati's great Italian one. The last reminds us of the name of the Snowdrop in that land of the south—*Pianterella*. How musical it sounds! Far more so than the German *Schneeglöckchen* (Snow Bell), or even the French *Perce Neige*. Benserade, the poet, has given us an exquisite verse, in which he makes the flower tell of its birth under the snow. Unfortunately it is in the language of "La Belle France," and thus hardly suitable for quotation here as it stands, and the writer cannot venture to put it into English verse. A prose paraphrase rendered somewhat roughly would express the thought after this fashion:—"The earth covered by a veil of silver, despite her coldness, gives me birth. The snow preserves my life, and, giving me her name, gives me also her purity."

One is tempted to linger among such thoughts of the flower, but we must leave them to look at it from another point of view.

The so-called "autumn-flowering" Snowdrops dallied by the way, and some, like the hare in the well-known fable, were overtaken in the race by others, which one would naturally expect to fall far behind. Among the earliest of these was one of Mr. James Allen's seedlings named Aurora. It has received an appropriate name so far as its early habit goes, and it is, moreover, a beautiful and shapely flower. When we see such charming blossoms as these one cannot wonder at the confession of that true lover of flowers, the Rev. H. Ewbank, in the Journal of January 28th. that he has often tried to pick Mr. Allen's brains. As Mr. Ewbank says, some of his Snowdrops are "extraordinarily lovely."

Such a one is Aurora, which a letter received from our good and generous friend, Mr. Allen, only recently, says is a seedling from *Galanthus Melvillei* major, but is quite different from its parent. It is one of the flowers to care for, as giving our gardens greater interest and higher types of beauty. Here one cannot

refrain from having a friendly difference with the talented Vicar of St. John's, always, of course, from a gardening point of view. In an earlier instalment of his delightful paper he is a little too severe upon the florists' points of perfection in a flower. Yet, after all, Mr. Allen's new Snowdrops, which he admires, are selected, one can easily see, upon the principles which guide the florist in his work.

The writer knows, both from Mr. Ewbank's public writings and his letters, which it is always a pleasure to receive, that he has much in common with him in the way of kindred tastes in gardening. It is likely enough, however, that Mr. Ewbank's criticism was meant mainly for that spirit which would carry the florist's art far beyond its proper bounds, and which has doubtless in too many cases given us monstrosity instead of shapeliness, and ugliness instead of beauty. There is, however, a sphere in which the florist can operate without debasing the flower. When he goes beyond this a protest is needed, and Mr. Ewbank's words, if so limited in their aims, are not uncalled for. Unless one is mistaken there is not very much difference at bottom between us.

Another very striking Snowdrop which has come early into flower is the best form of *G. Imperati*, which is named *Atkinsi*. It is extremely fine this year, and is well worth trying to obtain. Deep planting is very desirable with this fine Snowdrop as well as with most others. A good seedling Snowdrop raised in Lanarkshire has also been very early. This I have named *Fenella*. It is large, robust, and of capital form. Its parentage is *plicatus* × *nivalis*, and it differs from the most of those raised in the same garden by reason of its greater earliness. *Galanthus caucasicus* has also been in bloom for some time. The small size of the flowers is, however, a defect in this species; they are too small to be in keeping with the length of the stem. The leaves are the chief merit of this Snowdrop; they are not fully produced until the flowers are past, but are very broad and fine.

G. Alleni, in rather stiff soil at the base of a rockery, is coming on well. Then *G. flavescens*, one of the few with yellow instead of green markings, and with yellow ovary, has been coming on quickly, although the look of the plants would lead one to think that the yellow, which is its distinctive feature, will be less pronounced than usual. *G. Elwesi Beauty*, another of Mr. Allen's seedlings, is also very fine—or rather was before the snow, and will be once more when it goes again.

The dreaded Snowdrop fungus has again made its appearance in one part of the garden, where it was introduced by roots brought from a neighbouring wood. Whenever it is observed all that can be taken away is removed, and put in the fire of the greenhouse boiler. The fungus shows itself in a white mould-like mass on the surface of the soil just where the stalk of the flower comes through. The stalk will be found to be rotted down for a little distance, and ought to be removed and burned also. Mr. Allen has found several cases of fungus in his garden this year again, but one must hope that that successful Snowdrop raiser may not have once more to deplore the loss of some good flowers.

Here the early Irises are rather late, but Mr. Allen tells me that on New Year's Day the first of his opened at Shepton Mallet. This was a very pale blue form of *Iris reticulata* of great beauty and hardiness, although not robust, nor increasing rapidly. The Netted Iris is so very beautiful that we could well do with a few more varieties. We want more workers in the field of raising seedlings of bulbous flowers not taken in hand by the ordinary raiser of plants from seed. It would be wrong to hold out a prospect of reward in the shape of £ s. d., that is unlikely to follow so readily as to repay anyone for their time and care, but the pleasure of adding new plants to our gardens would be some recompense.

That was an interesting article on "Hepaticas" which appeared in the Journal of January 28th (page 76) from the pen of "R. P. B." The "ash-coloured or argentrive" variety the writer also would like to know more about. "Ash-coloured" would hardly answer the description of either of the varieties of *H. angulosa*, which, by the way, your correspondent is to be congratulated on flowering so successfully. The double white one has been in cultivation in this century, as, in addition to two acquaintances of my own who have seen it, a flower was sent from Germany to the office of one of the gardening papers ("The Chronicle") in 1895 or 1894, and mentioned by the editor in its columns. Is not "*H. trifolia aureum*" one of the Anemones, as distinguished from the Hepaticas, really Anemones also? The writer read in a series of articles on Canadian wild flowers, which appeared in a Montreal newspaper, the following, applied to the Hepatica:—"The colours of the flowers are white, many a shade of blue, and rarely a pale yellow." The italics are mine.

Upon particular inquiry of competent authorities in Canada no confirmation of a pale yellow Hepatica can be received. There are many seedlings in my garden, some of which have flowered, and others are in bud now. There are several interesting shades

among them. "R. P. B." will likely find that his one with deep pink flowers (if not the single of the double red) is that named *splendens*.

When the snow clears away again we shall have more to tell of, and may return again to the Hepaticas, unless other flowers take up more space to their exclusion. There are some Crocuses under the snowy pall, and one or two clumps of Daffodils far advanced, besides *Hyacinthus azureus*, and a few other things. We wait eagerly and expectantly for their re-appearance.—S. ARNOTT.

LOOKING ROUND.

"How are you? Glad to see you! Come and have a look round," says the gardener when he meets a fellow craftsman. The invitation seems to fall from the lips in a matter of course kind of way, as if it were the most natural thing he could do. Perhaps it is brought about by force of habit, at any rate it is one of the characteristics peculiar to gardeners, the why and wherefore of which it would be difficult, if not impossible, to explain. In every occupation there are habits and customs which seem to pervade the whole fraternity, and by an unwritten law they appear to be confined to the limits of the calling. In the world of horticulture these peculiarities are numerous, and perhaps no one would be more surprised than gardeners themselves if some adept in the art of character study were to portray them and give us an opportunity of "seeing ourselves as others see us." Let us just take one of these characteristics—the gardener's idea of relaxation. Change is necessary for the well-being of all men, for without it the round of everyday life would become monotonous and irksome. It is, however, the gardener's way of spending these little breaks in the daily round that calls for comment.

The idea of most men at holiday times is to get as far away from the associations of business as possible. The Stock Exchange man when he takes his annual vacation abjures even his daily paper, lest his eye, through force of habit, should wander to the columns relating to the money market; the hard-worked barrister throws aside wig and gown, and for the time being forgets parchment and red tape; while the city clerk and shopman forswear even a mention of the daily grind during the period that holidays last. In this respect the gardener differs; holiday would to him be no holiday if he were deprived from talking "shop," and his idea of spending days of relaxation is "looking round" the establishments under the care of brother craftsmen, his own in turn being subject to a similar inspection. Accounts of these visits often find their way into the columns of the Journal, by which the army of readers may note what is going on in other establishments.

Well, everyone to his taste, and a gardener experiences no greater pleasure than inspecting the handiwork of, and having a chat with a brother-in-arms. Not long ago a gentleman sent his gardener on a visit to London, paying his expenses, and telling him to be sure and see all the sights. On his return the generous employer naturally made inquiries as to what our friend had seen. Had he been to Westminster Abbey? Oh, yes. And on questioning the gardener as to what attracted him most there, he was surprised to hear that it was the fine show of bedding in Parliament Square. Another gardener, on visiting the Crystal Palace, thought it was a pity that so much glass should have been wasted in its construction, "as it would have built some grand ranges of greenhouses." These are only small matters, but show how keen is the interest of horticulturists centred in their occupation.

Let us look for a moment at the average gardener at home. Could anything be more enthusiastic and real than the heartiness with which he welcomes a friend in the craft who has called to have "a look round?" He takes the whole situation in at a glance, and after the friendly "How d'ye do?" follows the genial "Come on" as he leads the way through the houses. Then there is an interesting dialogue, and it would be difficult to say which is the more engrossed, guide or visitor—the former telling how he has raised this, or the trouble he has experienced over the growth of that, and so forth; while the former makes eager inquiries as to methods of cultivation adopted with anything that particularly strikes his fancy. Argument, of course, has its place, for in nothing does opinion differ so much as in gardening. One man grows a plant or crop in his own way; his method is successful, and he is prepared to swear by it. Another follows a different system, though the principle of the two may be alike; he also is prepared to stand by his opinion. Hence the argument.

To the casual observer there does not appear to be much consistency in many of our methods, and to the probationer this must often be puzzling. Here is a gardener who makes a speciality of *Malmaison* Carnations—does them really well, and follows the practice of syringing the plants with success. He, of course,

advocates his system, and believes in no other. On the other hand there is a gardener who also grows this beautiful Carnation equally well, but in strict opposition to the syringing system, never on any account allowing the foliage to be moistened. He is equally vehement in his advocacy of his practice, and in condemnation of that of the former grower. It is when "looking round" that argumentative force is brought to bear on each side, the end of it all being that opinions remain much about the same. But which is right? may be the question naturally asked. To all appearance results prove that both are, and the advice is in such cases, and they are by no means few, "Use your own judgment, and follow that which answers best."

As a means of education, nothing is more instructive to the gardener than a "look round" the establishments under the care of others, for the simple reason that there is always something to learn. Here is a gardener who is puzzled over the failure of a particular crop. He tries various ways and means till he has exhausted his own store of knowledge, and still he is unsuccessful. It occurs to him that an acquaintance of his succeeds in growing that with which he fails. Ah! happy thought, he will choose an early opportunity of going to see his friend—"have a look round," and at the same time obtain from him the desired information. By such means one gardener is able to render practical assistance to another in a way that is perfectly understood by the fraternity. There are, of course, seasons for gardening visits, and among Chrysanthemum enthusiasts the flowering period of the autumn queen is the favoured time. Emulated, perhaps, by a spirit of rivalry, and with that desire to know what everyone else has got so common to the craft, "Mum struck" gardeners exchange their friendly visits of inspection and criticism.

Then there is the social feature, or, in other words, that spirit of friendliness so conspicuous amongst gardeners. Perhaps in no other occupation does this exist to a similar extent. Note again "the look round." The visiting gardener notices a particular plant and admires it. "Has he got it?" No, but would like a few cuttings. Certainly, and straightway a few are taken off. Watch him again as he takes his leave; he has quite a burden of cuttings and plants, yet no idea of imposition ever occurs to him, as he knows full well when his friend repays the visit he will return similarly laden. So the feeling is mutual, and one takes a real interest in the well-being of the other. Then in times of adversity the gardener turns for sympathy, and, what is more practical, assistance, to a brother in the calling, and rarely comes away disappointed. The latter is a pleasant and gratifying feature, speaking volumes for the good fellowship that exists.

Keen indeed is the spirit of competition that everywhere exists, yet the enmity common in most trades and professions is markedly absent among gardeners. There appears to be an under-current of good feeling that knits one to another. It is one of the most gratifying phases of the craft, and is particularly noticeable in the hearty welcome extended by the average gardener when you call to have "a look round."—MONOCK.

BARE WALLS.

How seldom do we see the walls of lean-to houses covered with really useful creepers or plants? If it be a vinery Roses sometimes are employed for the purpose, but I have usually noticed they are not very satisfactory, as the temperature necessary for the well-being of the Vines at certain periods of their growth is unsuitable for Roses. Moreover, the laterals of the Vines extending over the roof greatly obstruct both light and sun from the Roses.

Where appreciated there is nothing better for the purpose than the South African Asparagus, *A. plumosus nanus*, or *A. tenuissimus*. The former to the floral decorator is an inestimable aid in almost any kind of arrangement, the sprays having the valuable property of retaining their freshness in water for a week or two. The latter is quite distinct from *A. p. nanus*, and better adapted, perhaps, for entwining around the slender stems of many glass vases than that species. I have found strong thread secured to a peg driven into the border at the base, fastening the other end to the top wire of the roof, one of the best ways of training, the thread being easily withdrawn after cutting.

Polygonum complexum also succeeds well under similar treatment, and is an excellent creeper if it is desired to furnish a wall quickly. (*Smilax*) *Myrsiphyllum asparagoides* is an excellent scandent plant belonging to the Lilyworts, and nearly allied to the genus *Asparagus*, and I have found a wall at the back of the stove or intermediate house answer very well for this species. It requires more heat than can be given in a vinery during the winter. The trailing branches are admirably adapted for dinner-table decoration, or when in bloom for the embellishment of a lady's hair. It should be trained up thread similar to the preceding. *Ficus repens* is well adapted for the purpose on a moist wall, while Maidenhair Ferns have also a very pleasing appearance.—GEORGE HAGON, *Fowley*.

FORCING VEGETABLES.

SEAKALE.

SEAKALE is a very easily forced vegetable, and can be had ready for the table by the first week in December. I prefer the crowns to have a slight frost or two before making a start, though at times this does not take place so early in this mild climate of Devon. Consequently a start must be made to introduce the earliest the first week in November. As a rule the majority of its growth is off by this date, especially if a frost has occurred. In lifting the roots care must be exercised that the crowns are not bruised, and all the tap roots should be broken off and preserved to choose cuttings from. In my case I plant about 1500 early in March, and these are the crowns that are forced the following autumn. The whole batch is lifted about the middle of December and laid in thickly together outdoors, and the crowns just covered with soil. Should severe frost occur, some long litter is placed over them so that they can be readily got at when required. I find the earliest take rather a higher temperature to start them than later lots, say early in the New Year.

A Mushroom house which keeps about 55° to 60° is a very suitable place. The crowns can be placed closely together, and should have sifted leaf soil worked lightly around the roots and up level with the top of the crown; a can of water should be kept there, and the crowns syringed daily. To keep up a succession I put in fifty crowns each week, but the number, of course, can be easily altered more or less according to the requirements of the establishment. The roots can also be forced in large pots or boxes and placed under stages, or any odd corner in a forcing house. These must be covered with pots or boxes, as no light must reach the crowns in any stage of their growth, or blanching will not be perfect. Neither must they be subjected to too much heat at this date (February), 50° to 55° is quite high enough.

The best place to force this vegetable (that is, those who adopt the plan I do and lift all their roots) is to erect a shed-like place about 12 feet long, 8 feet wide, and 4 feet 6 inches high, with twelve posts 5-inch square, four on each side and four in the centre to take the sides and top, rough planks 2 to 3 inches, which should be nailed to those around the sides about 1½ inch apart. The top should be of oak, and rather stouter than the slabs used for the sides, so as to be able to carry the weight of leaves necessary to give the required heat. This little building should have a small door on the south side to get in and out; the other three sides should have from 2 to 3 feet in width of good Oak and Beech leaves if possible placed around it, and the same thickness on the top. The material should be well trodden as the work proceeds. I keep adding to this as the leaves are brought in should the weather be cold; but if mild the first named will be sufficient, though the grower must exercise his own discretion on this point, and see the place does not get too hot. I keep a thermometer hanging up inside, and if, when mild outside, it does not register above 60° all will be well. This heat from leaves is not so drying as from hot-water pipes. Some sifted leaf soil should have been got in readiness and placed inside to plant the roots in. I also keep a can of water and the syringe in here to damp the surroundings when at all dry.

In passing, it may not be out of place to add that there is no better place to bring Rhubarb on than here in this little hut, if I may so term it. Delicious Kale, and Rhubarb as crisp and blanched as it is possible to get them, can be forced here. These details apply to lifted roots only. I now come to forcing crowns as they stand in the open ground. Of course, these are given a much wider berth than those grown and lifted; they should be planted in groups or clumps of three to six, 1 foot apart, with 3 feet or more space between each clump, to allow for Seakale pots and heating material, which should be composed of fresh leaves three parts, the rest of stable litter; this should have been thrown together and mixed before. This must be packed around the pots and above them to the height of 30 to 36 inches. It will take six to eight weeks to get it ready for use this way, and, of course, can be had in by Christmas very well. A few test sticks should be placed in the heating material to ascertain how the heat is. What you have to avoid is too much heat, as the roots soon burn. Plants should be so treated about every three weeks or a month. The decayed leaves should be removed and the soil lightly forked up prior to forcing, the crowns earthed up a little way, and a small quantity of litter placed between them, as I do not consider it as well if the ground gets frozen very much. Excellent heads, and probably a trifle larger than the nine or ten-months-old crowns I have forced for several years past, can be brought on this way, and for several years in succession, but a new plantation should be made every three years or so.

Another method I have seen adopted with fairly good results, where I was once foreman in Herefordshire—a square was allotted to brick pits about 18 feet long by 3 feet 6 inches wide. These were pigeon-holed and were about 5 feet deep, and every alternate one was filled with fermenting material, while the others were planted with three rows of crowns, and were forced three years and then replanted, a part being done each year. Over these crowns span-shaped shutters were placed and long straw litter placed over these, and made secure against frost and wind. This was always ready by Christmas. Success is obtained with each method, but for myself I prefer raising the whole crop and replanting each year. The cuttings are planted 1 foot apart in the row by 18 inches, and given a rich plot. A late supply can be had by leaving a few rows, and banking up with soil before the crowns start to grow. I have seen fine heads obtained by this means.—[Paper read by Mr. J. MAYNE, *Bicton*, at a Meeting of the Devon and Exeter Gardeners' Association.]

(To be continued.)

WEATHER IN LONDON.—On the whole milder weather has prevailed throughout the past seven days. On Thursday it was dull but dry, while during the afternoon of Friday the sun shone brilliantly, though rain fell during the evening, as it did at intervals on Saturday. Sunday was fine; Monday bringing a drizzling rain, clearing towards night. No rain fell on Tuesday, a damp fog hanging over the City during the forenoon. At the time of going to press on Wednesday it was bright.

WEATHER IN THE NORTH.—For a day or two there was a return of frost during the past week, 9° being registered on the morning of the 11th; 11° and 7° following. Thaw set in on Saturday with dense fog and rain generally over the country. Sunday was very wet throughout. On Monday morning there was a slight touch of frost followed by a good dullish day. Tuesday morning was fresh and pleasant, with the thermometer at 43°.—B. D., *S. Perthshire*.

VICTORIAN FRUIT CLASS AT SHREWSBURY.—We understand that a specially large class of sixty dishes of fruit will be provided at the Shrewsbury Show, with prizes of something like £30 and the gold medal of the Worshipful Company of Fruiterers as the first prize; £25 and the silver Knightian medal of the Royal Horticultural Society; and £20, with the silver medal of the Shropshire Society, as the remaining prizes. We do not know the precise terms of the proposed competition, but presume they will be published very shortly.

THE NATIONAL VIOLA SOCIETY.—The first annual general meeting of the members was held on the 10th inst. at Winchester House, Old Broad Street, E.C., when there was a large attendance, Mr. W. Robinson (the President) occupying the chair. A very favourable report of the work carried out by the Society during its first year, together with a balance-sheet showing that the Society had been able to meet all expenses and carry forward a small balance, was adopted. The following officers were re-elected for the ensuing year:—Mr. W. Robinson, President; Dr. Shackleton, Chairman of Committee; Mr. H. A. Needs, Hon. Treasurer; Mr. A. J. Rowberry, Hon. Secretary; while Messrs. C. Jordan of Regent's Park and J. Moorman of Victoria Park were elected to fill two vacancies on the Committee. It was decided, subject to arrangement with the Council of the Royal Botanic Society, to hold a show in the Society's Gardens, and also carry out another trial of Violas and Conference during the coming summer, a sub-Committee having been re-appointed to undertake the work in connection with the latter. It was also decided to publish a report of the proceedings of the Conference, together with particulars of the result of the trial of Violas made last year in the Botanic Gardens, and copies (price 6s. each) may shortly be obtained from Mr. A. J. Rowberry, of The Crescent, South Woodford.

READING GARDENERS' ASSOCIATION.—The fortnightly meeting of the above Association was held on Monday evening, when Mr. Neve presided over a very large attendance of members. The lecture for the evening was "Soils and their Comparative Fertility," by Mr. Douglas A. Gilchrist, B.Sc. Edin. Taking up his subject, the lecturer explained that the fertility of soils might be divided into natural or inherent fertility and artificial fertility. The following were indications of natural fertility. The character of the general vegetation of a district, such as the trees and hedges, for instance, where the Ash is to be found doing well, the soil would be of a generally strong loam and damp subsoils, whilst on chalk and oolite formations the Beech would predominate. A good Thorn hedge showed that the soil was good. The herbage of common land generally indicated whether the soil is fertile or not. Then the colour and character of the soil and subsoil which may be seen at the edge of a ditch give a good indication of natural fertility or otherwise. Soils in order to be fertile must have all the ingredients of a plant food present in a suitable form, they must also be in a suitable condition as far as tilth is concerned. Reference was also made to the great work of the earthworm. Darwin was the first to recognise its value. Although many would consider that the casts caused a great disfigurement to their lawns, yet he could assure them that the worms were greatly improving the soil. Many questions were asked as to soils and manures, and a discussion followed.

AN EARLY WASP.—It might interest your readers to hear that a fine wasp was killed (indoors) on Thursday, February 11th last.—L.

Kew Guild.—The annual general meeting of the Kew Guild will be held in the Lecture Room of the Royal Gardens, Kew (entrance by Melon Yard Gate), on Thursday evening, February 25th, at half-past seven.

FLOWERS FROM THE SCILLY ISLANDS.—On one day last week 22 tons of flowers, in 4205 boxes, arrived at Penzance from the Scilly Islands, and were at once despatched by special train, half of the lot being consigned to London and the rest to Birmingham and the North.

STRIKING CARNATION CUTTINGS.—Mr. Bardney is behind the times. I root 90 per cent. in three weeks, inserting four cuttings round 3-inch pots in a compost of light, sharp soil, plunging these in a bottom heat of 70° to 75°. The cuttings are kept nearly air-tight under a hand-light, shaded according to sun.—BASSIL.

RAINFALL IN THE WEST RIDING.—There have been 2.43 inches rainfall (chiefly melted snow) registered here on the first five days of this month. The heaviest fall in twenty-four hours was on the 5th inst., when 1.16 inch was registered. Owing to the excessive wet, and the hardness of the ground through frost, floods are very prevalent. During January 2.62 inches rain fell on eighteen days.—GEO. SUMMERS, *Sandbeck Park*.

CRYSTAL PALACE—GARDEN SUPERINTENDENT.—Mr. Geo. Caselton has written to us:—"I beg to inform you that I have been engaged as Superintendent of the Garden Department of the Crystal Palace in place of Mr. Head, who has had to resign through ill health." We have also received from the address of Mr. Head the following correction:—"There appears to have been an error in some of the last week's gardening papers in stating that Mr. George Caselton has succeeded Mr. Head, who has resigned his appointment. This is not the case; but owing to Mr. Head's prolonged illness the Directors have deemed it advisable to appoint Mr. Caselton as Deputy during this year."

HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—At a meeting of the above Society, held in the Parish Schoolroom on Tuesday, February 9th, a paper was read by Mr. Geo. Wilson, gardener to Sir James Reckitt, Bart., Swanland Manor, on "Gardening, Past and Present." Our forefathers, he said, sought for knowledge and found it, and we are to a great extent reaping the benefit of their labours, therefore it is our duty to the next generation to take care that our legacy to them is not less than the one bequeathed to us. In fruit and vegetable culture we are not greatly in advance of the past. We have more improved appliances and better varieties, thanks to the untiring perseverance of our hybridists. But in flower and plant growing, also floral decorations, we have made great strides—fashions have changed; and it must be said for gardeners, that as a body they are not slow to acquire the new ideas and fancies of their employers, and endeavour to meet the requirements.—F. L. T.

THE DIAMOND JUBILEE CELEBRATION.—Horticultural proposals in relation to this celebration, associated with public subscriptions, have, beyond what is utterly impracticable, so far been of a purely charitable kind. It does look very much as if horticulture as a great national vocation would be found out in the cold absolutely in the end. I wish to make a practical suggestion in relation to the great fruit show at the Crystal Palace in the autumn, which should be, specially having regard to the event of the year, the greatest and grandest show of fruit ever held there. With a view to commemorate the Queen's long reign to some extent, the Council have arranged for a series of papers to be read on fruit progress, vegetable progress, and market gardening progress during the past sixty years. Nothing could well be more fitting or in harmony with the year's event and the occasion. Now, I should like to see specially invited collections of produce in three classes, conforming to the subjects of the papers; and to certain money prizes, not necessarily large, should be added silver medals, specially struck, to be called the Queen's Diamond Medals, and these be awarded to the respective collections. The only limit placed upon them should be space, which should be rigidly restricted, and they should be such as would exhibit progress in their respective sections. Vegetables have, we know, been tabooed at this great show, but no doubt that difficulty could, for one special purpose, be surmounted. Were a special subscription to this end promoted, we may expect it would be liberally responded to. Certainly the collections and competitions would arouse the greatest interest horticulturally.—A. D.

— GARDENING APPOINTMENT.—Mr. Henry Wilson, for the past three years foreman in the gardens at Benham Park, has been appointed as gardener to Viscount Falmouth, at Mereworth Castle, in succession to Mr. Markham, and enters on his duties on March 6th.

— BIRMINGHAM GARDENERS' ASSOCIATION.—The inaugural spring meeting of this Society was held recently, when Mr. James Deans gave an interesting and attractive lecture on "Ornamental Grasses," illustrated by an exhibition of several of the more useful species, both mounted and for practical use.

— PRUNUS DAVIDIANA.—This is the earliest of the many species of *Prunus* (which are grown for the sake of their flowering qualities) to open its blossoms. The first flowers are now open, February 12th, and if the weather keeps mild the trees in a few days will be a mass of bloom. The flowers are white, about 1 inch in diameter, and produced, as in the Almond and Peach, on the whole of the previous year's growth. Its earliness of flowering, together with its free-growing qualities, makes this Chinese species, with its red flowered variety *P. Davidiana v. rubra*, a plant which should be found in all gardens.—W.

— THE GARDEN OF THE LATE MR. CHARLES JENNER.—Pressure of other matters prevents me from saying more at present about the garden of the late Mr. Jenner than that I had the pleasure of seeing it, and that my copious notes could not be put into shape at the time on account of other things intervening. The garden and its collection were unique, and possibly a few notes on it might be acceptable could I tell of it as it was just after Mr. Jenner's death. I thank Mr. Williamson for his too flattering reference to me. I think he will agree with me in saying that the introducer to the public of "Crimson Rambler" exercised a wise discretion in changing the name from the original one.—S. ARNOTT.

— VARIETY IN NATURE.—Waiting ten minutes for a train last autumn, my companion hazarded that twenty species of plants grew on the high bank facing the station platform. Even my small experience had taught me how lavishly Nature sows her seed, and I put the figure conservatively at fifty; immediately beginning to count, I soon reached the twenty point, but after the thirtieth, progress was slower. Every few seconds, however, new leaf-forms would meet my eye, and when we heard the train whistle in the distance I had counted forty-eight. This was all I could master from the distance of 10 feet, so I stepped across the track and immediately saw two small herbs on this closer scrutiny. This made fifty; then I had to retreat to the getting-on side of the track. Thinking over the rich look of the area we counted from, I would now boldly place my estimate at seventy-five, though I shall probably never have a chance to list and verify my prophecy in that same place.—E. NEWLIN WILLIAMS (in "Meehans' Monthly.")

— HOAR FROST AS AN AIR PURIFIER.—In a memoir by Messrs. Petermann & Graftian, published by the Belgian Academy of Sciences, it is demonstrated that hoar frost is particularly rich in nitrogenous compounds, and therefore plays an important part in adding to the stock of nitrogenous matter in the forest, as well as to the purifying influence that forests exercise on atmospheric air. The frostwork attached to the branches of trees, being continually renewed, presents to the air a large surface for the absorption of all soluble matter that it carries, so that single trees and forests act like immense filters, purifying the air that circulates through them, and collecting from it nitrogenous combinations, which, being returned to the soil by a thaw, serve again as nutriment to plants, and thus re-enter the vital cycle. The amount of frost which the branches hold is often much greater than their own weight, and in a measured cube which touched the extremities of the branches of a given shrub the weight of the frostwork which they held exceeded 1 kilogram for each cubic metre of space. Carrying out this calculation to a forest area, it is quite possible that 7 lbs. of nitrogen are deposited on every acre during a severe frost. When frosts are formed to such an extent as to break branches by their own weight, the quantity of nitrogen given to the soil must be very considerable. It is held, therefore, with good reason, that the frost represents a very appreciable factor in collecting the reserve of nitrogen within forest areas, and if we add to this the nitrogen contained in the rain, the dew, and the fog, we can explain why, without any addition of this material, or without the intervention of those plants which collect it directly from the atmosphere, the forest vegetation is well supplied with nitrogen. These facts also show, says a contemporary, how the soil of forest areas grows richer in this element which is given to it by the detritus, or waste, of woodlands.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—On Saturday evening the fifth lecture of the season was delivered by Mr. H. Ranger of Messrs. Kerr & Son's Aigburth Nursery, his subject being "*Hippeastrum* or *Amaryllis*." Mr. T. White presided. As might have been expected the lecturer gave a thorough insight into its early history, dealing with the labours of Linnæus, Dean Herbert, Hooper, James Douglas, and H. Veitch. An interesting *resumé* on the early hybridising of the various species up to the gorgeous flowers of the present time was admirably given, as was also their culture, several handsome specimens being used as illustrations, showing with proper treatment the long period over which these handsome flowering bulbs may be prolonged. A pleasant discussion followed.

— A PROLIFIC HYACINTH.—Mr. Bardney writes:—"When at Norris Green, Liverpool, I grew thousands of Dutch Hyacinths, but we grow none here. The 'missus' and my daughter made up their minds they would have some, so the old glasses that had been stored away for years were brought out and some bulbs obtained, I think begged. They certainly have succeeded in a good display, a bit overforced, but they are exceedingly proud of their achievements, and claim to have 'beaten' me at last. One is certainly a profusion of bloom, and I never remember having seen one like it before. It has no less than six spikes—if it had been grown in a pot it would have made an exceedingly fine display. The central spike is good, and the five others issue practically altogether from one side of the bulb, having apparently no connection with the centre."

— THINNING APPLES.—Mr. S. D. Willard, at the meeting of the Ohio State Horticultural Society, spoke of an interesting experiment tried at Geneva last year. An orchard of Greening, Baldwin, and Hubbardston Apples was thinned on some of the rows so that an Apple was left every 4 inches, and on others so that there was only an Apple for every 6 inches. On the trees where no thinning whatever was done the Apples were small and hardly coloured; the Apples on the trees thinned to 4 inches apart were coloured well and of fair size, but no buds formed for the next season. On trees thinned to fruit 6 inches apart the Apples were large and so finely coloured as to attract the attention of passers on the road several rods away. Besides this there were well grown fruit buds for next year, so that, if nothing prevents, the trees will bear two seasons in succession.—("Garden and Forest.")

ROYAL HORTICULTURAL SOCIETY

SCIENTIFIC COMMITTEE—Present: Dr. M. T. Masters (in the chair); Rev. W. Wilks, Mr. Shea, Mr. McLachlan, and Rev. G. Henslow, Hon. Sec.

Coniferous Woods.—Dr. Masters exhibited specimens of Deodar, Larch, and Cedar of Lebanon grown by Mr. J. Simpson at Wharnccliffe. They were said to have been planted at the same time, about thirty years ago. It was remarkable that the heart wood of the Larch and Deodar were much alike, while that of the Cedar was different in not being so darkly coloured like the others. The quality was in each case good, especially that of the Larch. It has been observed by Dr. Tristram that the wood of the Cedars grown on Mount Lebanon is much closer in grain and darker in colour than that of trees grown in England ("The Nat. Hist. of the Bible," p. 343).

Species of Thuya.—Dr. Masters also exhibited specimens illustrative of confusion in the nomenclature of this genus. He observed that *T. occidentalis* grows in the Atlantic States of North America, and *T. gigantea* (Lobbi) on the north-western or Pacific side. A form originally named *T. plicata* was introduced at the end of the last century by Menzies from Vancouver. In Donn's "Catalogue of the Plants of the Botanic Gardens at Cambridge" this plant is recorded but without description. As this is a western species it is really synonymous with, or at most a variety of *T. gigantea*. But the original *T. plicata* having probably died out, the name *plicata* has now become transferred to a form or variety of *T. occidentalis* from the Atlantic side of the United States. It is probable that both species are represented by a "*plicata*" variety; but it is not certain whether the Pacific variety is now in cultivation. Specimens of the original *plicata* from Vancouver are in the Herbarium of the British Museum, so that it is a question whether, strictly speaking, the name *T. gigantea* should not be superseded by that of *T. plicata*. The plant now bearing that name should then be called *T. occidentalis* var. *plicata*.

AWARDS, FEBRUARY 9TH.—By an oversight the medals granted for exhibits at the meeting held on this date from our last issue. They were:—Floral Committee: Silver-gilt Flora, Messrs. H. Cannell & Sons, Swanley, Primulas; silver Flora, Messrs. J. Peed & Sons, Norwood, plants, and Mr. C. Turner, Slough, Cyclamens; silver Banksian, Mr. G. Wythes, Syon, hardy plants in pots, and Messrs. J. Laing & Sons, plants; bronze Banksian, P. Purnell, Esq., Streatham, Daffodils. Orchid Committee: Silver Flora, Messrs. J. Veitch & Sons, Ltd., Chelsea; silver Banksian, Messrs. H. Low & Co., Clapton; F. Sander & Co., St. Albans; L. Linden, Brussels.

MILTONIA ROEZLI.

WHILE plenty of small bits of this beautiful Orchid are to be seen it is seldom one comes across really well grown healthy specimens of large size. This is a great pity, for they are extremely beautiful when in flower. It is not so easy as many of the genus to cultivate, and the fact of a grower having produced specimens, say in pans a foot across, and well furnished to boot, is ample evidence of care and skill beyond the ordinary. Such plants I had the pleasure of inspecting recently, and though the blossoms were not all open, yet enough to show the beauty of the plants when so grown were expanded.

Individually the blossoms of *O. Roezli* are about 3 inches across, the typical form being pure white in ground colour, with a purple centre, and a little yellow about the crest. The variety *alba* has no purple markings, but simply the yellow on the crest of the lip; a chaste and lovely flower. The spikes proceed from the sheathing bases of the leaves, are erect, or slightly arching, according to their length, and each bears from three to six blossoms. The plant has a clustered habit of growth, and the rounded compressed pseudo-bulbs are almost hidden in the sheathing bases of the grey-green leaves. The roots call for no special comment, being similar to *M. vexillaria* and others, but all in this section have a great aversion to anything close or heavy about them.

This being so the greatest care must be taken in the preparation of the compost, and bearing on this is a fact that ought never to be lost sight of by those who wish to grow Orchids well, namely, that inferior material—at no matter how low a figure it may be offered—is much dearer in the long run than good stuff at a fair price. Peat, for instance, of the quality required for Orchid culture, is not obtainable everywhere, and those dealers who have choice cuts naturally make the best market they can of them. The small amount of waste in using this compared with the other class is an important point, but a still more important one is that in the one valuable plants will, if well treated in other ways, increase in value; in the other there is great risk of losing them altogether.

As a basis of the compost required for *M. Roezli*, nothing but good fibry peat and clean freshly gathered sphagnum moss is necessary; but as this, from its nature, would hold too much moisture and get into a very close condition, a free addition of finely broken crocks and charcoal must be made to it. Whether these are mixed with the other ingredients or added as potting proceeds is immaterial, some growers preferring one way, some the other; but if they are kept separate until the compost is being used it saves waste to a certain extent, and insures a more uniform mixture if this term can be allowed.

The best time to repot is when a flush of young roots from the forming pseudo-bulbs is imminent, generally when about half grown, this giving the plants a direct hold upon the new material. It may be taken as a general rule that the plants require repotting once in two years, the removal of a little of the surface and replacing with new compost sufficing for the intervening season. Disturb the plants no more than is absolutely necessary; but it is better to dislodge every root, even to wash them entirely clear of compost, than to return any sour or decayed material into the new pots. Drainage is an important item, and if the ordinary make of pots are used these must be filled quite two-thirds of their depth with clean crocks.

Perhaps more suitable are the shallow pans, pierced for suspending, and these must be quite half filled or a little over. Cover with a film of rough moss, and fix the plants firmly with the dibber. The base of the leading bulbs must be kept above the rim, and a neat cone-shaped mound of compost will receive them. Trim off all ragged ends of compost, carefully avoiding the young growths, with the scissors or shears, and replace the plants with as little delay as possible into their growing quarters. A position not far from the roof glass in a moist and well heated situation should be chosen for them, and they need only be shaded sufficiently to prevent injury to the foliage.

Last season I saw in a well-known collection a batch of this species plunged alongside a fine lot of *Vanda teres* in a totally unshaded end of a warm structure, and the conditions apparently suited them well. Until the roots are beginning to work freely after disturbance water very carefully, but keep the atmosphere very moist. At all other times the plants delight in copious supplies of water to the roots. Often when suspended from the

roof as described, the plants will take water daily, small ones of course needing it oftener than larger ones owing to the limited capacity of the receptacle wherein they are grown.

Perhaps the most frequent of all causes of failure is the attacks of thrips, to which *C. Roezli* is so subject. These insects of course are in evidence on many other Orchids, but they seem to quite paralyse the system of this species, and unless instant means of suppression are taken when they are first seen the plants will soon be entirely overrun, when their doom may be said to be sealed. I have often described the best means of destroying these insects by fumigation and sponging, so need say no more on that head at present; only give them no quarter. If the insects return after apparent destruction repeat the dose until the plants are really clean. *M. Roezli* is a native of New Grenada, and was introduced to this country in 1873.—H. R. R.

FLOWERING TREES AND SHRUBS.

DECIDUOUS.

BRITISH gardening has many phases, each interesting and enjoyable in its own particular way. Some of these are at times suddenly lifted to a pedestal of prominence by the ever changing tide of fashion; then after a brief—or it may be an extended—period of popularity the favoured aspect of our “gentle art” drops back into obscurity, often leaving but little trace behind to mark its reign of splendour. The above remarks are especially true in regard to the various styles of bedding which have at different periods been in vogue in our gardens, and of the numerous kinds of florists’ flowers so largely cultivated long ago, but which have left no trace behind save the memory of them.

Happily, however, there are other aspects of gardening in which the work of one generation descends to future ones as a priceless blessing, and forms a fitting monument to the foresight and skill of the grand old gardeners of the past. Many fine specimens of *Coniferae* and other trees which have made the gardens of Britain famous show how important a branch of horticulture arboriculture was then considered, and the many splendidly laid out grounds around stately mansions show that at least a few among the gardeners of the past possessed fine ideas upon that branch of their art. There still remains, however, one way of adding beauty to gardens of all descriptions which has not received the amount of attention it deserves, I refer to the planting of flowering trees and shrubs.

Much is being done in this direction in some modern gardens, but there are yet too many large masses of common evergreens planted without any attempt being made to render them attractive at various seasons by the aid of easily grown flowering trees. During recent years so many gems of this description have been introduced to this country, that there is variety enough to suit all tastes. Old time gardens had but a comparatively limited stock of materials to select from, and this perhaps accounts for the dearth of showy trees which many ancient gardens exhibit. This gives the present generation a splendid opportunity of enhancing the beauty of many a fine demesne by supplying the deficiency. The work may be easily done by planting masses at well chosen points in the foreground of shrubberies or belts of trees, and in some instances removing old and unsightly ones, to afford space for more attractive kinds.

Details about planting I hope to treat of in a subsequent article. I will therefore now proceed to give a concise description of some of the most useful and beautiful flowering trees and shrubs that I am acquainted with. Fortunately the noble family I have the honour to serve take great interest in these matters, and are constantly adding new species and varieties to the fine collection brought together by their ancestors, which collection is greatly admired by the many thousands of visitors who flock to Warwick Castle.

Alnus glutinosa aurea, the Golden Alder, is well worthy of a place in gardens where large shrubberies abound, as it forms a handsome bush, both leaves and flowers being attractive when growing in a sunny position. It thrives well on dry banks where many other shrubs do not, and on that account is especially useful, as there is often a difficulty in getting a bright bit of colour on steep banks where the soil is shallow.

Amelanchiers, or Snowy Mespilus, comprise several pretty spring flowering shrubs, which are easily grown in any fairly rich soil, and are readily propagated by cuttings in the autumn. *A. canadensis* (the Canadian Pear) is one of the most showy; it produces a wealth of white flowers in April, and seldom attains a height of more than 6 or 7 feet. In autumn the foliage is usually very attractive. *A. vulgaris* is also well worth growing on account of the freedom with which its white flowers are produced.

Amygdalus (Almond).—No class of flowering trees are more

generally admired than the Almonds. This is probably because they have so many good qualities. When in flower a well-grown specimen presents a sight that lingers in the memory, for each shoot is completely studded with delicate and attractive blossoms. Such a sight would in the month of May assuredly arrest attention; but when we consider that they usually flower in March it requires but little imagination to understand their great value.

A. communis is an old and well-known species, which forms a large handsome tree, and is well adapted for planting at wide distances apart in shrubberies, to give seasonable colouring. *A. communis amara* (Bitter Almond) bears larger flowers, rather paler in colour than the first named. *A. c. dulcis* (Sweet) usually

grows freely, and is the most attractive deciduous *Berberis* that I know. *Calycanthus* (American Allspice), *C. floridus*, and *C. occidentalis* are desirable shrubs to grow on account of the delicious scent their quaint flowers emit. A rich light or peaty soil suits them well. The positions ought to be well drained, and peat or leaf soil freely incorporated with the natural soil if this is heavy.

One has only to visit the Cherry orchards of some fruit-growing county when the trees are in flower, to form an idea of the great value of *Cerasus* for garden ornamentation, and yet many of the varieties grown for the latter purpose greatly exceed in beauty those to be met with in fruit orchards. The following are some of the best varieties for garden culture—*C. Mahaleb*, white, height

FIG 31—*CERASUS PSEUDO-CERASUS*.

flowers slightly in advance of both, and the flowers though smaller are of an attractive red colour. *Pendula* and *purpurea* are two good forms of *dulcis*. On account of the early date at which those already enumerated flower, a somewhat sheltered position should if possible be selected for them.

In the several varieties of *A. persica flore-pleno* we have a delightful race of dwarf free-flowering shrubs, suitable alike for pot culture, or for planting on banks or in the foreground of shrubberies. If grown in the form of standards they ought not to be planted among strong-growing shrubs, as they do not make rapid progress. Crimson, rose, and white forms may be obtained. *Amygdalus persica magnifica*, which received the award of a first-class certificate from the Royal Horticultural Society in February, 1894, is the most attractive of the dwarf semi-double varieties.

Berberis vulgaris is too well known to need description, but it is well worth growing. *B. Thunbergi* is a comparatively recent introduction, having beautiful lemon yellow drooping flowers. It

10 feet; *C. Padas* (Bird Cherry), 20 to 30 feet; *C. serrulata* (double Chinese Cherry), very handsome and showy flowers, white tinted with rose, height 10 to 15 feet; *C. sinensis pendula rosea*, very attractive in colour; and *C. pseudo-cerasus* (fig. 31) is a very beautiful variety that was staged at the Drill Hall, last spring, by Messrs. J. Veitch & Sons, Ltd., and received an award of merit. The flowers are large, and delicate blush white in colour.

Cercis siliquastrum (Judas Tree) and *Chimonanthus fragrans* are two somewhat peculiar yet attractive shrubs that ought to be grown in every large garden, not perhaps in quantity, but to give variety. The first named flowers during the summer months, and the latter in January or February. In cold districts both should be given the shelter of a wall. Then what have we more charming than *Pyrus Malus floribunda* and *P. spectabile*?

The month of May, with its tender leaves and wealth of flowers in England owes much of its charm to the profusion of Hawthorn trees and bushes in full bloom. We meet with them on all sides,

in the woods and hedges as well as in gardens; their flower-wreathed branches and shapely outlines are pictures of perfect beauty. With the exception of *C. pyracantha*—which produces bright scarlet berries, and is extremely useful for covering walls and buildings—the *Crataegus* grown in gardens are varieties of *C. oxyacantha*. Some of the best are *C. coccinea plena* (Paul's double variety), *C. foliis argenteis*, *C. multiplex*, *C. præcox* (Glastonbury Thorn), *C. punicea* (scarlet-flowering), *C. flore-pleno* (double red), *C. rosea* (pink flowering) and *C. semperflorens*. Hawthorns are usually planted in the form of standards, but as bushes they are also extremely attractive, and wherever they are planted, on the banks of a lake or river, I strongly advise that the bush form be selected.

In my schoolboy days I claimed a strip of garden of my own, in which, growing against a wall, was a fine old plant of *Cydonia japonica*. It received but little attention in the way of pruning, and invariably flowered splendidly each year. When in full beauty my firm conviction was that no garden in our neighbourhood could show anything more lovely at that season; perhaps I was right, for it certainly is one of the "gems" among spring flowering shrubs, suitable alike for growing against a wall or as a bush in an isolated position. *C. Maulei* is a more recent introduction which bears bright red flowers, slightly smaller than those of *japonica*. The habit of growth is also more compact. Other good varieties are *C. coccinea*, *C. flore-pleno*, and *C. rosea*.—H. DUNKIN, *Castle Gardens, Warwick*.

(To be continued.)

A GARDEN IN THE ISLE OF WIGHT.

[An Address (amplified) by Rev. H. EWBANK to the members of the Horticultural Association at Newport.]

(Continued from page 98.)

Now we come to the most delightful season of the year, when the cuckoo is heard and the nightingale sings, and when Irises blossom, not by twos and threes, but in large companies. They are my favourites among all the flowers of the year. Their hues are so varied and delicate; their shapes so fantastic; the contrasts which abound are so bold and striking; the foliage is so pleasant that an Iris garden always has the highest attractions for me. Dr. Foster, the Professor of Physiology at Cambridge, is the greatest authority about Irises, and at one time and another he has been very kind in giving me help. If an Iris has a fault it can only be found in the fact that its blossom is so very fugacious. Mr. Caparn tells us that "the majority of Iris blooms have a three-days span of existence," and that one of them, "*Iris sisyrinchium*, blooms from midday to three o'clock, when, worn out with old age, it curls and dies." Irises, he says, inhabit the temperate regions of the earth. "There is no meridian of longitude in the land of our northern temperate zone untenanted by an Iris. In latitude the greatest abundance appears towards the warm temperate region of 40°, while they rapidly thin out below 30° or beyond 60°."

There are two English species (*foetidissima* and *Pseudacorus*); France has ten species; Portugal and Spain contribute some bulbous ones; Germany, Hungary, South Russia, and Turkey add to the list. Some few are found in America, a few in China and Japan, but the best of all the Irises are those which come from Asia Minor, Palestine, and Central Asia itself. The groups are divided, according to Mr. Baker, by "the varying characters of the very conspicuous raised line running along the middle of the outer or drooping petal-fall of the flower. In the two groups of bulbous and beardless this line is a raised or convex ridge. In two other groups there is more or less thick line of hair-like bristles. In a fifth the ridge of hair is spread out into a broad flat cushion. A sixth section has the line produced into a crest or comb, cut and frilled very much in the same manner as a cock's." "The Iris is an historical flower, and after the battle of Crecy was united with the arms of England, and remained so until in the union with Ireland the Shamrock took its place. Strangely enough a fleur de lis exactly like that of the emblem of the French monarchy was found surmounting a sceptre in a monument at Dendara in the heart of Egypt."

I can only just mention some two or three species. *Iris florentina*, which is the emblem of the French monarchy, is a most beautiful flower; its colour is white, just tinged with lavender. *Iris aurea* is from the Himalayas, and of a bright golden yellow. *Iris pallida dalmatica* is very large and fragrant; it comes from Southern Europe and Western Asia. *Iris spuria* is also from Southern Europe, and very much to be admired.

But best of all, the most striking among all the flowers of this earth, I hold the *Oncocyclus* section to be. They are, however, very difficult to grow, and afford a most delightful puzzle to those who take any interest in them. They come from the plains of Asia—from the northern regions of Palestine, from the fastnesses of the Caucasus, from Persia, and other places. Some few were introduced by a botanist who accompanied the Russian armies into Asia, and who forwarded them to Dr. Regel at St. Petersburg, by whom they were distributed to Herr Max Leichtlin and others. They certainly are, to my mind, the most fascinating of all flowers, and of a very aristocratic appearance and of extraordinary shapes; the tracing on the petals is exquisitely delicate. The contrasts which they offer are bold in the extreme. Some of them have a very silvery hue, and there is often a transparency about them which

greatly adds to the general effect. The blossom is very large, and out of all proportion to the size of the plant; the leaves are narrow and sickle shaped.

The habit of these Irises in their own homes is so utterly out of harmony with anything which they find here that there must be contrivance if they are ever to do well at all. Mr. Selfe Leonard has well observed "That, on the one hand, it can scarcely be that the requirements cannot be imitated in this climate, albeit that the right method may prove to be disagreeably elaborate and artificial," for it is difficult to see how anyone can expect to accommodate these denizens of the East with what they want unless there be some manœuvring for it. If it can be done at all surely that is enough for all practical purposes, and if their desires are to be hit off we must follow their bidding. I wrote some time ago to Max Leichtlin of Baden-Baden, who is the most eminent horticulturist of the day, for instruction on this matter. His answer was, "I often had importations of these *Oncocyclus*, and wherever anything did adhere to the roots it was hard ferruginous clay. This in winter and spring is covered with snow; when melting the snow is reduced to pulp for some weeks. After this summer begins, and occasional thunderstorms and rains keep the soil provided with some moisture. In summer it gradually dries and becomes as hard as a brick, and keeps the roots warm and dry."

"In ordinary winters the dryness in Asia Minor goes on till middle or end of November, then come a few showers, and soon after snowstorms." I had to translate this into the practice of horticulture—and let me say there are two ways of growing these Irises, one is of taking them up and keeping them dry for months, but this is a barbarous method, for it lacerates and injures the roots; in such a country, however, as Holland it is inevitable, because the subsoil is always so full of water. The other method I will try to describe to you, and to it I adhere. You will see at once how different the surroundings of these Irises are in their own country from anything they get here. There is a great gush of water when the hard frost breaks up, and then they are dry for the summer months, and become utterly baked; if they are kept green, and have no rest in summer, there will be no blossom in the succeeding year. The difficulty, therefore, is to account for their peculiarities; so, to copy their natural surroundings as to coax these plants into flowering, they must be put under glass for a time, for there is no other way of keeping them quite dry in summer, and this is not enough, because of the moisture which rises up from below—very little sets an Iris growing.

I have found that a platform about 8 inches below the soil made of old paving stones with interstices to let the water off is a good thing. If the drainage is not good—if there is the slightest stagnation—there is sure to be a good deal of damage at once, and then I raise the beds about 4 inches above the surrounding level, so that the water may in great measure trickle off from them. There must also be good ventilation; but in winter there must still be a sufficiency of moisture, so that the Irises may be able to grow. In this sort of way I have succeeded in blossoming nearly every one of these *Oncocyclus* Irises, and I have now about 700 of them, which look as prosperous and happy as they well can do. I will close this brief notice of *Oncocyclus* Irises by quoting an opinion or two of Prof. Michael Foster regarding them. He says about *Iris Gatesi*, "To my mind, this Iris, when seen at its best, with standards and falls fully unfolded, and its delicate tint not yet marred by bruises, raindrops, or the beginnings of witherings, is of surpassing grace and beauty." About *I. paradoxa* he writes:—"The total effect of the flower is very striking, and, unless an element of grotesqueness be thought inconsistent with beauty, very beautiful." About a variety of *Irisiberica* which he got from Kurdistan, he says, "It is one of the most lovely flowers I know." See "Garden," February 18th, 1893. And Mr. Caparn is of the same mind when he says, "April and May, with those happy people who can grow the *Oncocyclus* group of Irises, is the cream of the whole year." See *Journal of Royal Horticultural Society*, August, 1896.

A few words must now be given to the Rose, though with such rosarians in the island as Messrs. Jeans and Spittall, they need not be many. My friend Mr. William Paul has said that "throughout the civilised world undisputed precedence among flowers is given to the Rose. In the sacred writings, by classical authors, by poets of all countries, including our own Chaucer downwards, this queen of flowers is an epitome of beauty and fragrance. It has often been the subject of scientific monographs and floricultural disquisitions, and its cultivation affords employment to thousands of human beings for the manufacture of rose water and attar. To take only one instance of the great store set upon it, if there is any period of the world's history when flowers engrossed too much the attention of a nation it was under the reigns of Augustus and subsequent Emperors of Rome. The love of flowers was then carried to excess, and the Rose seemed to bear away the palm from all."

"It was customary for the wealthy inhabitants to take their meals resting on Rose leaves, a practice which Cicero loudly condemns. Roses were scattered upon the beds and floors of the chambers of their guests. In times of public rejoicing the sheets were strewn with flowers, and the statues of the deities were adorned with crowns and garlands of Roses. Suetonius relates of the Emperor Nero that he spent four millions of sesterces, £30,000, in procuring Roses for one feast." Of this, however, enough. One can only think what a glorious time it must have been for the Messrs. Paul and Cant of those days.

I have given this encomium at length, because its glowing terms can hardly be exceeded, and no lover of Roses could wish for anything more; but I do not intend to dwell myself upon the queen of flowers, one reason being that it is an interminable subject, and I have no room left for it; another reason being that it has been already exhaustively handled by those who are much more competent to touch it than I profess to be. I will merely give the names of a few species which are

grown in this garden, and which are not commonly met with, and I will add a few passing remarks. In chapter xvi. of his "Notes in a Gloucestershire Garden," Canon Ellacombe has given us a very interesting account of Roses.

The first that I would mention is *Rosa berberidifolia*, otherwise called *R. simplicifolia*. It is a native of Northern Persia, and the desert of Songari in Chinese Tartary, and has baffled the attentions of many a gardener until now. I should think that Dr. Lindley must almost have lost his temper over it, and it must have been like a good riddance of bad rubbish in his eyes when it ceased to try him so much. As a last resort he prescribes a saline draught for it, much in the way that a black draught may be prescribed for a very recalcitrant patient, partly to punish him, and partly to do him good. All, however, that I have to say about the matter is this—and I consider it to be greatly to the credit of the climate of the Isle of Wight that it is so. *Rosa berberidifolia* has not caused me the slightest anxiety since it came into my hands. It was most kindly given to me at Kew some five or six years ago, and it took to this place at once without the least intention of leaving it. I know that at Salisbury the same Rose covered itself with blossom, and then it was so surprised with its effort that it expired upon the spot; but mine has not had an experience of that sort at all. My Rose has grown to a large size, and if it were left quite alone it would be advancing all over the bed where it is situated, but it has not made any great advertisement of itself. It has blossomed in a restrained and gentle way, and I think modesty will meet with its proper reward; but if it should ever be otherwise, and self-assertion should get the better of the plant, I believe I shall then be safe, for my Rose has laid its foundations deep, not only in one spot but in several, by sending out suckers on every side. But I know that I can only rejoice with trembling about this matter, although I give what has occurred up to date.

The winter, however, of 1894-5 was surely a pretty good test, and a very simple glass cover about the size of a dog kennel was even then protection enough. The flowers of *Rosa berberidifolia* are solitary, cup-shaped, and the petals are of a deep yellow with a crimson spot at their base. The leaves are sessile, erect, narrow, obovate, &c. Altogether it looks more like a *Cistus* than anything else at a little distance, and Dr. Lindley is abundantly justified when he speaks of it as a "lovely plant." The next Rose I would mention is *Rosa gigantea*, and here I can only speak of a very qualified success, if, indeed, it be success at all. *Rosa gigantea* seemed very happy against a wall for a long time, but what Burmese flower or tree could have stood up against that terrible ordeal of 1894-5? All I can say is that it did its very best to get through it. I lovingly covered it, tended it, helped it through days and nights of bitter frost and cold, and so well did it seem to me to be getting on that when the great frost had passed by I quite imagined that my Rose was safe, and the bitterness of death had been escaped; but it was not so at all, for it had been somehow fatally smitten, and it passed away with a smile, I might almost say, on its face in the spring.

But that experience has, I quite believe, put *Rosa gigantea* into my hands, it made such a good fight for life that I think it will conquer next time. Let us hope that we shall never have such a long frost again as that of 1894-5, and I have found a rather warmer spot for the glorious specimen which I at present possess, and which promises great things. *Rosa gigantea* was discovered in Upper Burmah by General Collett in 1888. It is a pure white single Rose, and 6 inches across the petals. I am vastly indebted to the Director of Kew Gardens for so kindly letting me have a second chance with it.

Rosa Wichuriana, I believe, comes from China. I am told that it blossoms abundantly. It has deep green shining evergreen foliage, and is well adapted to a rockery, as it falls over the stones in a graceful manner. *Rosa minutifolia* is the latest acquisition of all. It only came into my hands about ten days ago. Dr. Engelmann wrote this from California about it to Mr. Thompson of Ipswich, from whom I had it: "You will see that this Rose will make a sensation in Rose circles if only if can be got to England alive. It forms bushy plants, with very slender stems, thickly set with minute spines, and varying in length, and furnished with delicate foliage and two pairs of pinnae, and a terminal odd one, each leaflet being a quarter to one-third of an inch in length, broadly oval and sharply toothed, and strongly veined." I give this description at length, because it is a new plant. At present it is in my greenhouse, and it is an open question as to whether I shall ever dare to plant it in the ground at all. One thing may be predicated about it for certain. It will never make the sensation which Dr. Engelmann looks for; it is much too pretty for that. A few names must end this short notice of Roses which are under my care. *R. bracteata*, *R. rubrifolia*, *R. rugosa*, *R. lucida*, *R. indica*, *R. ferox*, and others too are all doing well here. *R. viridiflora* is one of the few flowers that must be called positively ugly.

Lilies, with one exception, I must leave severely alone—for I have to be in St. John's Church to-morrow morning at eleven o'clock. Last spring an officer in Burmah (Captain Grant) sent me a box full of bulbs, of which I gave away some and potted the rest, putting them in cocoa fibre under a north wall, &c. As soon as they started I planted them out in a *Rhododendron* bed in peaty soil. All through the summer they grew in a languid way, if they grew at all. I thought nothing would come of them, and I went on the Continent for seven or eight weeks. On my return I was greeted with one of the most glorious apparitions I have ever beheld. Several large heads of *Lilium Lowi* were in full blossom towards the end of October. The blossoms were large, funnel shaped, yellow, with blotches of yellow on them, and altogether among the finest flowers of the year. I suppose the sudden deluge of rain in September suited them, after the great heat in the summer.

(To be continued.)

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last the Committee of this Society held a meeting at Anderton's Hotel, Fleet Street, Mr. B. Wynne occupying the chair. Proofs of the photograph of the medal awarded to the Society for its exhibit at the Ghent show were submitted and approved of preparatory to the same being presented to the members who contributed the blooms. Some discussion arose on the subject of the new regulation that the Floral Committee should in future meet at three o'clock in the afternoon, and that resolution was upheld.

A great part of the evening was occupied with considering the draft report, financial statement, and new elections to be laid before the annual meeting on Monday next, when Mr. R. Ballantine is expected to preside. New members were elected, and societies at Tonbridge, Warringham, and Penzance were admitted in affiliation.

GOOD KEEPING VARIETIES.

THROUGH force of circumstances I have had an exceptional opportunity of testing the keeping qualities of some varieties of Chrysanthemums this season, and I thought a note on the subject may be of some interest to your readers. Through a delay in the erection of a greenhouse I was compelled to keep about 150 plants that had been treated on the cut-down system out of doors under the protection of a north-east wall until the end of October. I intended keeping what I could for Christmas decoration. The lean-to house in which they were subsequently placed faced nearly east, with front and back ventilation, and had no artificial heat whatever. By the end of November some very fair flowers were developing, and as the season was exceptionally wet and dull, with an occasional frost, I felt the chance of keeping any under the circumstances very remote. Still, as an object lesson I was determined that all should take their chance without any extra precaution whatever, only in ventilation.

By about the first week in December I found Madame Carnot the first to go, showing the susceptibility to injury by damp and cold. Six plants bearing six flowers each, only about three parts developed, went evenly spotted all over. Vivian Morel and Chas. Davis also soon went. Louise, and some finely developed Rose Wynne, Col. Chase, Col. W. B. Smith, H. L. Sunderbruck, Mons. Pankoucke, and Good Gracious was the next to go in the same way—evenly spotted over all the florets at first, then a gradual rot and decay. For Christmas I was able to use the following varieties in good condition, grown in the same house, and under the same conditions as the foregoing.

Souvenir de Petite Amie.—This was solid, clean, and good; a first-rate keeper. Directeur Tisserand, Niveus, Mrs. C. E. Shea, this I think will turn out a capital late variety. Mons. Chas. Molin, a very good keeper. President Armand, Phœbus, M. Chenon de Lecbe, Golden Gate, also an excellent late variety. Incendrie and Richard Dean, Emily Silsbury, and Edith Tabor withstood the damping, but became tinged earlier than the foregoing. Of the incurved varieties Chas. Curtis kept well, also James Agate, Robert Petfield, and Baron Hirsch were the only other varieties of a small collection that kept fit for use.

I do not intend to convey that all the foregoing are naturally late varieties, but they are good keepers when grown for late work. Mons. Georges Biron, Golden Gate, Mrs. C. E. Shea, and Duchess of York are naturally late with me. I regard Mrs. C. E. Shea as a good late variety to grow for market purposes, also Souvenir de Petite Amie, and Mons. Chas. Molin, are exceptionally good keepers.—C. ORCHARD, *Bembriège, I.W.*

GREEN AND WHITE CUCUMBERS.

IN a former number of the *Journal of Horticulture* (May 7th, 1896) I described the cultivation of plants of the white Cucumber, and the production by one of them of green fruit. I stated further that the seed of the green Cucumber should be cultivated. This has been done, and the result I now communicate to you.

Four plants obtained from the seed of that Cucumber were set out for observation. They grew fairly well, though the season was unfavourable, and they bore only green fruit. The result seems to show that the white variety has but a temporary existence in comparison with the green kind, for at the end of ten years one of the seeds, as we see, reverts to the green type, and probably many others would have undergone the same change if all the seeds of a whole Cucumber had been planted. It also seems to show that the green Cucumber is the parent form, from which the white springs as a variety or sport of nature.

The existence of the white fruit is very rare in England, being unknown to most people I find, but in France it is by no means uncommon. I have been informed by Mr. Bunyard, the well-known horticulturist of Maidstone, that a white Cucumber (albino) occasionally springs from seed delivered as green in this country from France, and that the French seedsmen offer to supply you with mixed white and green Cucumber seeds, or with seeds of the white sort alone. This difference in the two countries is very remarkable. The common supposition that this colour change is due to the crossing of the one kind

with the pollen of the other does not appear to me to explain Nature's work. A somewhat similar change is observed in the production of flowers, both coloured and variegated, from the same seeds without artificial crossing or impregnation with pollen.—GEO. VINER ELLIS.

THE POTATO IN PERFECTION.

I AM happy to detail my experience of Potato cookery on this side of the Channel, in response to "J. E.'s" note of interrogation on page 115. Possibly we are not, as a people, so accomplished in the matter as he infers, from reasons to be shown; but, however that may be, Ireland should certainly, from the prominent part the Potato has so long played in its food economy, lead the way in cooking the esculent tuber. In the first place, those portions of the island where the Potato is practically the staple food, have, from its deterioration by continued cropping on "sick" ground, the employment of the refuse as seed, and other causes, ably expounded at our recent tercentenary, left good cooking results out of the question where we might reasonably expect to find the best examples of the simple culinary art practised. Hence, unfortunately, the Potato in perfection is rarely to be met with.

I fear also, in spite of our sympathetic friend's praise, that many visitors to Dublin, if their visit is confined to the "cardrivingest" city, may be disappointed at the way, if not in the quality, of the Potatoes served by those who cater for the public. One first-class restaurant, indeed, which is in the hands of a gentleman well known as an accomplished amateur gardener, gives all the attention to the matter it deserves, and one will there find served with their *pièce de résistance* a brace of Sutton's Main Crop in their jackets, satisfying in all points. But, again, we as a race do not favour a long kidney shaped Potato, and I fear there is in this catering just a *souffçon* of Anglo-mania attached to it which, I trust, will never reach the cooking, and serving up in the nude, for that would illustrate the description given by an Irish girl whose sister had served with an English family in London—viz., "Oh! she's real Englified now, and peels the Potatoes." A reliable round variety is, taken all round, the Potato for us, and I think English friends will appreciate us and our Potatoes better by retaining our character than by any attempts at being "Englified."

Between these two extremes—the metropolis and the impoverished West—there is doubtless ample ground and opportunity for sampling the Potato in perfection. Presupposing that His Excellency's remarks at the tercentenary, which possibly may be taken, like Potatoes, *cum grano salis*, leave an opening for our English friends to learn from Irish cooks, I will come to the point (the boiling point) with a few simple rules observed in these localities. The Potato must be cooked in his jacket, consequently he should have a clean and slightly one, a point each for cook and gardener to remember. Whatever variety is favoured the character of that variety and its behaviour in the pot must be studied. For instance, the "Champion" (champion no longer), in use for years, was found to give the best results when the water was strained off at the half-boiled stage, and the operation again resumed with cold water. Another little point, but important, is to select tubers of the same size for the one boiling.

If it is found necessary to soak the Potato late in the season in order to restore any watery particles which may have evaporated under storage in a dry place (which is a bad place) two or three hours in water, unpeeled I beg and insist, is sufficient for the purpose. Place them in sufficient cold water to well cover them, to which, when brought to the boil, add a liberal sprinkling of salt; then previously to their being done quite through strain off, and let the steam finish the process. One Irish lassie who took pride in the task (only she would occasionally forget the salt) used at this stage to put a clean napkin over the Potatoes, and replace the lid for the finishing process. It is an excellent plan.

The highest possible of Potato cookery I have seen was that in which the dishing up completed, I believe, the perfect results. This was in a nobleman's establishment where the Potatoes, cooked as above described, were served up in wooden bowls, the contents of each bowl being covered with a napkin, which was whisked off at the last moment on the table. This led on one occasion to a remark from a lady's lady that "the food was served up in troughs, the same as for pigs," a remark as relevant as that of a gentleman's gentleman at the same table, whose sea voyage to reach this side led him to exclaim, "I shall advise my lord to go back all the way by train instead of having that beastly sea passage."

The wooden bowl is doubtless a relic of the times when trenchers and other vessels of wood were in vogue, including the Irish drinking cup, four-handled and square in shape. Some superb examples of Irish silversmiths' work are to be found in the antique Potato rings. These were probably used as stands for the bowls, possibly also in other ways for serving up the Potatoes, but are now prized as table ornaments by their fortunate possessors. I was lately speaking to a high-class cook on this subject, one who does not disdain to give the matter personal attention, and I was informed that when living in the vicinity of the sea, sea water was invariably used for cooking the tubers, and could not be excelled for the purpose.

Unfortunately high-class cooks appear, as a rule, to think the homely, yet indispensable Potato, beneath their notice, hence complaints abound. One gardener I knew, who was nearly as often in hot water, figuratively, as the Potatoes were, literally settled the matter of "bad Potatoes" by inviting "my lady" to sample his growing and Mrs. Gardener's cooking in his cottage. "Excellent," was the verdict. There is beauty in a

Potato, and joy in eating it when cooked to perfection, and there is, too, I believe, virtue in a wooden bowl when serving up on the altar of our necessities.—PADDY.

OUR most useful vegetable misused. Alas! it is so. Potatoes are left to chance, instead of being made the first consideration. On no account should the Potatoes wait for the rest of the dinner, and yet how often we see the Potatoes taken off the fire and put aside, so that the cook may warm up soup, fry fish, or make sauce! Potatoes should never be put into a steamer till the water boils. When done, must be served at once in a hot tureen. Roasted Potatoes are spoiled nine times out of ten by overcooking.

Then again, the quality of the Potato has a great deal to do with the preparation of a good dish. I would not risk my reputation as a cook by trying to prepare a Potato out of our kitchen garden, which is far too strong a soil, nor from other light sandy land in our occupation; nor will I guarantee to cook Potatoes that have been put up in a sack for an indefinite time and exposed to varying degrees of temperature. In paring a Potato I can tell by the feel if it is a good cooker, and experience soon teaches this. It is too early yet to steep Potatoes overnight in water; that is a good plan later, when there is much growth. A handful of salt and a few sprigs of Mint should be added. Doubtful Potatoes roast best. In steaming the heat must be uniform.

Bad land won't grow good Potatoes. Much may be done by manure, but the constitution of the land cannot be changed unless the cost exceed the value of the crop.

Potatoes are best cooked in middle-class households, where the mistress is at the head of kitchen affairs, and brings a little intelligence to bear on her work.—THE MISSUS.

[When doctors differ! "Place them in cold water," says "Paddy." "Potatoes should never be put in a steamer till the water boils," says "The Missus." "Paddy" has our sympathy in his unfortunate position. Can some County Council teacher on cookery come to the rescue?]

FLORICULTURE UNDER DIFFICULTIES.

IN these days of journalistic enterprise we hear a great deal about successful men. Sometimes we come across characters, born gardeners I will call them, who appear to have missed their vocation, and who, had their lot been cast in the calling would most probably have been amongst its shining lights. Such an instance once came before my notice, and is well worth relating.

It was at the Cardiff Show. The judges had made their awards and passed on, when a voice behind muttered "What a pity! I should ha' won easily." The speaker's appearance suggested that gardening was not his occupation. Moving away his next pause was before a group of trained Zonal Pelargoniums, and then with a look of disgust he started towards the exit, but stopped suddenly as if a new idea had struck him, and inquired whether we knew that "Thomas Hillard was not showing his plants this year." Going on to say—"It's like this, I've won prizes with my Fuchsias and 'Geraniums' for nearly twenty years at Cardiff Show, and this year after I'd got 'em potted, and they had started well, I learnt that the Committee had put a restriction on the size of the pots. Of course mine were too big, and I should ha' bin disqualified if I'd brought 'em. It is a pity, I should ha' 'walked in.' If I'd known before I'd potted my plants."

Making further inquiries we learnt that he was a shoemaker by trade and floriculture was his hobby. The idea of a shoemaker growing specimen Fuchsias and Pelargoniums appeared somewhat novel, but an invitation was given to see the plants at home. Those who are acquainted with Cardiff will know something of the neighbourhood adjoining the docks. The slimy, muddy looking water comes nearly up to the doors of the houses, and it is in Hodge's Yard near the docks that the shoemaker florist grows his plants. Every inhabitant of the Yard appeared to take a lively interest in the Fuchsias, and were profuse in regrets that their owner was prohibited from exhibiting. We regretted to find that the shoemaker's business had called him away from home, but soon learnt that his better half was almost as much a gardener as he himself.

The greenhouse itself deserves a word, being built in a style peculiarly its own. Several additions had evidently been made to the original structure, and its formation, if not elegant, is at any rate ingenious. The lower part of the house is of wood, heavily coated with tar; the side lights appear to have done former duty as window casements, and the roof presents a variety of angles and gradients. Entrance is effected by means of a doorway at one end, and if our surprise was great at the outside appearance it was infinitely greater when, by bending and squeezing, we got among the plants. Junior members of the Hillard family were busily engaged in watering the Fuchsias—magnificent specimens nearly 8 feet high, and wreathed with flowers from base to summit. It was impossible to get among the plants in a perpendicular position, and it was amusing to see the youngsters crawling between the pots on all fours with a watering can.

"How long has your husband grown Fuchsias?" we inquired.

"Well, we've had that plant about sixteen years," replied Mrs. Hillard, pointing to a superbly flowered specimen.

"Suppose you know them by name?"

"Oh, yes; there's Marguerite, Beacon, Charming, Mrs. Rundell, Gustave Doré, and several others." They were all splendid examples of culture, trained in pyramid shape, with points almost touching the roof.

"Your husband must take a great interest in the plants," we ventured.

"Oh, yes; he nearly lives amongst them when he is not at work, and I help him when any assistance is required."

"How often are they potted?"

"Early every spring," was the reply, "and when the plants are commencing to bloom we give them liquid manure."

To make an examination of the Pelargoniums was a more difficult matter, as they were on shelves near the glass, this rendering it quite impossible to see them from the inside. However, with the aid of a pair of steps we were enabled to see them through the glass roof. Never have we seen better plants; staked out in circular manner, and crowned with numerous large trusses of flower, both single and double. Amongst others we noted Raspail, Eureka, Minnie Parker, and Mark Twain. We could only surmise the amount of trouble and care that had been expended on the plants to bring them to such a high state of excellence.

"Your husband must have been very disappointed that he was not able to show," we remarked.

"Oh yes, he was," replied our informant. "You see he has taken first prize for 'Geraniums' at Cardiff for nineteen years, and would have stood a good chance again this time."

With this we fully agreed, as both Pelargoniums and Fuchsias were much superior to anything there was in the show. Proudly Mrs. Hillard displayed a trophy in the shape of a silver medal which was granted by the Cardiff Horticultural Society to her husband in 1893.

The visit to Hodge's Yard taught its lessons, as it was a striking instance of what can be done by a man amid adverse surroundings, and it seems a pity that such plants were not exhibited and honoured at the show.—G. H. H.

WEBB'S SENATOR PEA.

THIS fine early variety, of which a very correct life-size illustration is here given, had the merit of being not merely the earliest but the heaviest cropping of all the wrinkled Marrow Peas grown in the Surrey county trials at Richmond and Chertsey last year. I am not in a position to compare it with such early rounds as William the First or Eclipse, or with the dwarf wrinkled Chelsea Gem or William Hurst; but I have no hesitation in classing it also as one of the best and most productive early wrinkled Marrows in cultivation.

The trials at Richmond and Chertsey were limited to varieties of medium height and suitable for second early or main crops. In both places Senator was noted by the allotment holders with great avidity; indeed, a better early Pea for their purposes, and to furnish fine, handsome, well-filled pods early, could hardly have been found. It was as well at home on the stiff loam of Chertsey as on the light fibrous soil of Richmond, and some grown in boys' gardens at Reigate on pure sand gave the instructor there the greatest satisfaction. The variety will be grown with twenty others at Sarbiton this season and also at Bookham on very diverse soil. In many if not most cases fine Peas are seriously handicapped by thick sowing. All varieties are sown thinly in the Surrey trials, so as to do justice to them and insure a correct test of merit. Half a pint of good seed is sufficient for a row 40 feet in length.—A. DEAN.

MEMORIES OF EXHIBITIONS.

WHAT I have to say on this subject will be simply recollections of what I have seen at flowershows during the past thirty-five years. My first visit to a flower show was in 1861, at which time I was garden boy under a noted Hollyhock and Dahlia grower. We used to grow blooms of the first named equal to any I have seen since, and it is to be regretted that such a noble decorative plant as the Hollyhock should have become almost a thing of the past.

The first large flower show that I attended was held at Grantham, under the auspices of the South Lincolnshire Horticultural Society. The principal features in the plant department were some splendid Fuchsias, ranging from 3 to 5 feet in height, forming perfect pyramids of flowers. The plants in this class were not to exceed one year old. Stove and greenhouse plants were also well represented.

Looking back after this long lapse of years, I feel sure the display of fruit was fully equal both in quantity and quality to that seen at our best shows at the present time. In the principal classes six or seven competitors exhibited splendid Grapes, both Hamburgs and Muscats; also grand Melons, Peaches, Nectarines, and Figs. Four of the exhibitors had fine specimens of the Queen and Smooth Cayenne Pines; in fact, in those days Pines were well grown in nearly all the principal gardens in the country, but in these more go-a-head times the culture of Pines has almost gone out of date. Still, after all, there is nothing equal to a noble Pine amongst the dishes of dessert at a large dinner party.

My next experience in the exhibiting line was when sent with several boxes of fruit to the summer show at the Crystal Palace in 1864, and never shall I forget the day of delight spent in examining the different exhibits. The monster Azaleas of Mr. Turner of Slough and others impressed me greatly; perfect pyramids, ranging from 6 to 9 feet high, and from 4 to 6 feet through at the base, every plant completely

covered with bloom, many of the brighter coloured varieties being dazzling in their beauty. The stove and greenhouse plants were also marvels of culture, and there seemed to be hundreds of specimens; amongst them splendid examples of Ixoras, Allamandas, Dipladenias, Francisceas, Stephanotis, Ipomæas, Ericas, Apelexis, Leschenaultias (both biloba and formosa), and many New Holland plants now almost out of cultivation.

Orchids also were largely represented, mostly *bonâ fide* specimens, not made-up plants. Vandas and Aërides from 3 to 6 feet high, some having eight and ten splendid growths in No. 1 pots. Cattleyas and Lælias were equally well grown and flowered, while Phalænopsis, Cymbidiums, Dendrobiums, and others could scarcely be equalled at the present day. The Roses in pots of Messrs. Paul of Cheshunt and Waltham Cross, Turner of Slough, and others were better than it has been my pleasure to look upon in later years.

My next show was at the Royal Botanic Gardens, Regent's Park, and here the arrangements for the display of the plants exhibited were the most perfect I have ever seen—namely, large mounds and tiers of growing turf in circles and semicircles, some mounds having two tiers

FIG. 32 —WEBB'S SENATOR PEA.

and others three or four. I have often thought that many of our leading societies might with advantage copy this excellent method, for what can be more incongruous than to see splendid specimen plants elevated on rough wooden stages varying in height from 2 to 6 feet? Some at York last year were, I think, higher in one of the tents.

Twenty years ago very few specimens of Palms were seen, either at the shows or in private gardens, and no one can deny that the introduction of such plants as Kentias, Coccoses, and Geonomas has done much to elevate the taste of the British public. We sometimes saw good plants of *Latania borbonica*, *Cycas revoluta*, and *Cordyline indivisa*. Our foliage plants then included Tree Ferns, the Bird's-nest Fern, and Yuccas. Marantas and Alocasias were also well grown at that time, and the Crotons were simply marvellous. Their size and colouring, although there were only three species then in general cultivation—viz., *variegatus*, *pictus*, and *angustifolius*; but the plants of the latter, as shown by Messrs. Baines and Cole, were superior to any exhibited before or since, being almost like fountains of gold in their matchless beauty.

I have mentioned the names of Messrs. Baines and Cole, and I have no hesitation in saying that they were the very best plantmen of this century. It was the custom for many of our societies to offer valuable prizes for twenty-five and in some cases fifty distinct varieties of flowering and foliage stove and greenhouse plants, and even in these large classes a weak plant could not be found. A few years ago it almost seemed as if specimen stove and greenhouse plants in bloom were vanishing, but thanks to such men as Messrs. Cypher, Finch, and a few other growers there is a proof that the culture of these triumphs of the floral world has not altogether become a lost art, and I trust the day is far distant when

lack of exhibitors may compel committees of horticultural societies to strike these classes out of their schedules.

The largest and most complete exhibition of plants I can remember was the International Exhibition of 1866, held under the auspices of the Royal Horticultural Society. Nearly every home and Continental firm of repute was represented, and such magnificent plants have seldom been seen in such numbers. Large specimen Orchids grown in tubs produced a striking effect, as also did huge plants of *Eucharis amazonica* some 8 feet in diameter, and carrying from sixty to one hundred spikes of bloom, grown by Mr. Howard of Balham.

The largest exhibition of fruit I have seen was at Manchester in 1874. Grapes were superb. Mr. Hunter of Lambton Castle was the champion in many of the fruit classes, one bunch of Black Hamburgh Grapes weighing over 21 lbs, the largest bunch of this variety on record.

It has fallen to my lot to take some part at many of our best shows, and I do not doubt that many of my younger hearers will be saying to themselves, "You have told us plenty about the shows of twenty to thirty years ago. What about the shows of the present day?" My opinion is this. Taking them all in all they are the best exhibitions of horticultural produce the world has ever seen, and no country can equal our own in producing such splendid examples of Nature's boundless wealth, both in fruits, flowers, and vegetables; and why is this? It is not that we have the most suitable climate, or the best appliances, or the most fertile soil; but it is simply that the Anglo-Saxon people possess such indomitable perseverance that they will not be beaten by any other country, either in war or in the milder pursuits of peace.

To my mind the greatest advance that has been made in popularising our horticultural shows has been brought about by the introduction of classes for groups of plants arranged for effect. What a remarkable degree of excellence this feature has now reached, and it must be gratifying to the members of our little Hesse Society to know that we have amongst us men who have repeatedly taken a foremost place in these classes even at our largest and best shows, where the competition is most keen; also we have one who has never suffered defeat in any competition of this kind, and I sincerely hope he never will. I consider him not only the champion exhibitor of groups of plants, but the pioneer in training and teaching others what good groups ought to be. He is no copyist; his ideas are as original as they are beautifully carried out, and we all hope the future may have many more triumphs in store for him. After the groups I think the classes for bouquets, stands of flowers, tasteful arrangements for table and other decorations have made immense strides during the past few years, and this improvement, as exemplified at our shows, has done much to advance the national mind in tone, taste, and refinement. There has been a great advance in the quality and culture of florists' flowers, such as Roses, Chrysanthemums, Begonias, Gloxinias, Lilies, Carnations, and many others too numerous to mention here.

True, there are some classes that are now seldom seen. I refer to those for rare plants, both exotic and British, also British Ferns. At one time there were classes at York for twenty-four and thirty-six distinct varieties of British plants. The loss of these classes has been much felt by many, but their removal had become necessary so as to make room for more showy exhibits, for, after all, we are not all botanists, and cannot fall in love only with that which is most rare.

Now just a word or two on the compilation of schedules for our large shows. My opinion is that these schedules should contain classes for everything that can be produced in good condition at the time of the show, and which may be grown in sufficient numbers to bring out a strong competition. I think also that the prizes offered should be as proportionate as possible in value with the merits of the exhibits, and in no case should a first prize be in excess of the second and third combined. It is very hard on any exhibitor who may miss the first prize by a single point to lose £5. Some may say this is the fortune of war, but when gardeners have to pay all their own expenses as exhibitors, it is the misfortunes of war that trouble them the most.

The number of horticultural shows has largely increased during the past few years, but unfortunately the reverse has been the case in our own immediate neighbourhood, but even about here several village shows have been inaugurated recently, and are doing some good, but I should like to see good summer shows at Hull, Beverley, Hesse, and Cottingham. These need not injure any of the existing village shows, which are more especially for amateurs and cottagers, and in these shows I should like to see three or four villages grouped.

Before closing I must give a little advice to my young friends, who may in the future have the chance and inclination of entering the lists of exhibitors at some of our leading shows. First of all send for a schedule as soon as they are published, read it carefully through, paying particular attention to its rules and regulations, then mark the classes in which you consider you have the best chance of competing successfully. Having done this leave no stone unturned to make the very best of the material at your disposal. Keep your plants thoroughly clean (also their pots), and work them up into the best possible health, while in training study the natural contour of the plant, and retain it as far as possible. If the plant is a climbing kind, as a rule an oval-shaped balloon is suitable. Whatever method you adopt try and hide all your stakes and ties, remove all dead or dying foliage, see that everything is correctly named, and time your flowering plants to be at their very best on the day of the show. This matter is the most difficult of all, and can only be done successfully after much experience, and you will soon find that ten times more labour and skill are requisite in producing good flowering plants on the day of the show than in the production of good foliage plants. Another thing, all who aspire to be good plantmen

should keep trying their hands upon the most difficult plants to grow, for depend upon it a difficult thing well done always tells its own tale. There is far more pleasure and credit in showing well a difficult plant than in staging something that can be grown with ease.

When the important day arrives he at the show in good time with your exhibits; go steadily to work, making the very best of everything you have by staging as effectively as possible, then calmly await the verdict. If you meet with defeat look carefully around and see where and how you have been beaten, and determine quietly but determinedly to reverse the positions in the future, and success will eventually crown your efforts.—(Read by MR. CHAS. LAWTON at a Meeting of the Hesse Gardeners' Mutual Improvement Society.)

THE YOUNG GARDENERS' DOMAIN.

R.H.S. EXAMINATION.

ON page 122 "W. R. R." asks if the date given in my advice—viz., the first week in February, is correct. The date named was taken from the R.H.S.'s Journal, but on a form I received from the Secretary I found it stated, "This form must be returned not later than the 16th of March." On page 114 of last week's *Journal of Horticulture* it states, "Candidates wishing to sit for examination should make application during February." I should think the date mentioned on the form—namely, the 16th of March, may be taken as correct.—A STUDENT.

It is not without a feeling of trepidation that I take up my pen to offer a few remarks on the above subject. Your correspondent "Subordinate," page 17, seems a little disheartened at only gaining a third class certificate at the last exam; to him I would like to offer a few words of encouragement, and wish him better success next time. "If at first you do not succeed try again" is an old motto, and a very good one; remember Rome was not built in a day, so if our worthy friend persevere who knows but what he may be in the first class next time?

I was a candidate at the last exam, and I have no reason to be disheartened with the result, although I did not come off with first honours. But apart from that, I derived much benefit from studying for the occasion and object. I think it is a grand thing when we know some of the great scientific principles which underlie our work, which knowledge can only be obtained from books by the greater part of young gardeners.

Our friend says he felt ashamed of himself being beaten by a porter. It seems rather hard on a man who has spent sixteen years under some of the best gardeners in the country, but it appears the porter is very enthusiastic over his garden, and may have spent much time studying why certain things are done and what they are done for, with the result that he stands before our more practical friend. These men may, and sometimes do, pass the exam easier than the majority of young gardeners; but I quite agree with "Subordinate" that they are not qualified for the position of head gardener, and no doubt they know it.

I quite approve of examinations, and think that a knowledge of theory combined with practice is most desirable. Still the R.H.S. exam is no criterion of a man's skill in the garden. It is well to have a certificate from the Society; but of what use is it to a young gardener, even if a first-class, when applying for a situation without one from his chief for practical work, who is the better able to testify as to a man's capabilities?

I should like to make a suggestion, however. If the exam is to take on with young gardeners they should have a class to themselves. How can we expect to compete with men who have the advantage of years' more experience, not forgetting the students from Swanley College and the Central Laboratory, Chelmsford? I should like to know a little about these institutions. I wonder if these students could compete with us in actual work, such as digging, mowing, wheeling, stoking, fumigating, and all other duties which the young gardener has to fulfil? What would the ladies think of us if we were to go in for examinations in dairying, dressmaking, or cookery, although I am sure the latter would be very useful to many of us.

I think there is very great credit due to those young gardeners who do pass when they have such rivals to compete with. I think many more would enter if they had a class to themselves, or for gardeners only. I venture to say there would then be plenty of candidates from all parts of the country. I should like to hear the opinions of other young gardeners on this interesting subject.—NOVICE.

GLOXINIAS.

So strikingly beautiful are these gorgeous plants when well grown that they fully deserve the reputation they enjoy of being among the most desirable of florists' flowers, and considering their comparatively easy culture, the wonder is they are not more largely grown. A stock of plants may be raised in the following manner.

Procure a packet of seed from a reliable source. This is of first importance, for unless the seed is obtained from a good strain, good results cannot be expected. Well crock some thoroughly clean, shallow seed pans, fill them with a mixture of leaf soil and sand, soak with tepid water, and allow to drain. Sow the seed thinly on the moist surface, placing the pans covered with squares of glass on a gentle hotbed; excluding light until germination takes place, when they will require a position on a shelf near the glass.

As soon as the tiny seedlings can be fairly seen prick them off 2 inches apart in shallow boxes, using for this operation two pieces of stick, one in the form of a prong for lifting the seedlings, as they are

much too small for handling with the fingers. When the plants have made four leaves they may be placed in 3 or 4-inch pots, these being found ample for the first season. During bright weather shade carefully from the sun. As the plants bloom select those that are desirable, and after flowering gradually withhold water from them, and finally place them on their sides under the stage in a cool greenhouse, where the tubers may pass the winter.

In the early months of the year any desired number may be started at intervals of three weeks to insure a succession of bloom. Pot the tubers in small pots, and place them in a house where the temperature does not fall below 50° at night. Water carefully at first, increasing the supply as the plants grow. Although Gloxinias are lovers of moisture, anything approaching stagnation is highly prejudicial, therefore always drain sufficiently. They delight in shade, and for compost nothing seems to suit them better than a mixture of three parts well decayed leaf mould, one part each of loam and sand, with the addition of a light sprinkling of soot to impart colour to the foliage. For ordinary establishments 5 or 6-inch pots will be found large enough for flowering the plants in unless they be required for exhibition, when pots of larger dimensions may be brought into use.—YOUNGSTER.

CHRYSANTHEMUMS.

IN preparing Chrysanthemum cuttings, especially for exhibition, I insert two cuttings in each 3-inch pot employed in providing between 500 and 600 plants, which are grown for large blooms. They root quicker by the side of pot than in centre, and the young plants do not feel the slightest check from dividing and potting singly, but the roots take to the fresh soil at once. I find after repeated trials that they do equally as well, if not better, than those rooted singly. Although this mode is wrong, according to most of our leading Chrysanthemum growers, anyone pressed for room during December and January need not be afraid giving the plan a trial. We have won many prizes at the leading shows in Ireland from plants so treated. I also find that first-class blooms can be cut off plants struck in heat in February and March, many varieties coming in at the right time for the November shows, whereas if the same varieties were rooted in December or January would be too early.

As many persons will be throwing out their old stools of Chrysanthemums now, I advise them to save a plant of each of the following:—Vivian Morel, C. Davis, F. Davis, Col. W. B. Smith, Mdle. M. Hoste, Souvenir de Petite Amie, Emily Silsbury, Mutual Friend, Phœbus, and W. H. Lincoln; and insert cuttings in April and May. Pinch the April-struck cuttings well back the first week in June, and take the first bud. May cuttings, unless they are off the stem or tops of tall shoots, require no pinching, and generally show a bud the first week of August. Stem cuttings and tops must be pinched when well rooted.

Allow only one flower to each plant. Many of these blooms will equal in size those from plants grown in large pots, while these late-raised plants will be only from 12 inches to 18 inches high if grown cool and have abundance of room during the summer. Many others give fine blooms, only they grow too tall; Duchess of Wellington, Col. Chase, and Duke of York doing extra well but for their height. I saw this plan recommended several years ago, and have since grown an increasing number of these plants. They are the admiration of all visitors, and most useful for house decoration.—W. T., Ireland.

STRAWBERRIES FOR FORCING.

IF it is intended that layers are to be taken from young plants towards the end of July, make a plantation large enough to throw sufficient runners for next year's stock. Plant 1 foot apart in rows 1 foot 6 inches asunder. If the season be dry afford good waterings until the plants have taken to the soil. Winter past and growth commenced, try all means to obtain good plants. The Dutch hoe is very useful, not only in keeping down weeds, but stirring the surface soil is very beneficial to growth. It is good practice to take off all flower trusses as they appear on these small plants, thus throwing the vigour of the plant into the runners.

When sufficient runners are produced with good plantlets attached, layering is commenced. Use 3-inch pots, filled with a root-enticing compost; stop the runner at the joint, and fix the plantlet with a small pebble or peg; pebbles are best, as they retain the moisture in the soil. Give water on bright days, sprinkling the foliage at night, and do not allow the plants to become dry. In about three weeks they will be well rooted, when they should be detached and taken where they will be handy for potting. If possible stand them in a shady place.

For fruiting use 5 and 6-inch pots, according to the variety. The compost should consist of five parts loam, one of spent Mushroom bed refuse, a 6-inch potful of a good fertiliser, some bonemeal, and a 3-inch one of soot to each barrowload. In potting see that all the plants are moist. Do not bury the crown, pot firmly, leaving 1 inch of space on the top of each pot. Stand in a shady place for a few days, afterwards take them to their summer quarters. Stand all the pots on boards or some hard surface as a preventive against worms. Face the crowns south, they will ripen better. Be sparing with water until the roots are working freely. Keep the soil free from weeds, all runners picked off, also side crowns as they appear, only allowing the central one, better fruits are obtained from it. On the evenings of bright days sprinkling the leaves is very beneficial. During the season the plants derive benefit from an occasional application of liquid manure water.

When cold weather sets in take the plants to their winter quarters. Cold frames are best; where these cannot be spared, space must be found where protection from heavy rain, snow, and frost can be afforded. On

favourable days remove all protection, endeavouring to keep the plants as hard as possible. On no account allow them to suffer by drought at the roots.—SEMPER.

(To be continued.)

GRAPE VINES.

I ALWAYS read with interest anything written on Grape culture, therefore the articles by "W. T." and "H. H." have not escaped my notice. "W. T." tells us on page 80 that "they always damp down with liquid manure water, as ammonia from it helps to keep Vines free from spider." I have placed Vine leaves infested with red spider in an atmosphere so strongly charged with ammonia as to make it impossible to breathe in it, and although the leaves were all scorched up not one of the spiders was killed. "H. H.," page 123, says, "In order to induce the Vines to break evenly at the time of starting they should be bent in a semicircular form. By doing this part of the sap is directed to the back buds instead of rushing to the top of the Vine." A few years ago this was our practice with about 4000 Vines. Seeing how badly some canes broke I found on examining the wood cells that they were ruptured near the bend, consequently the buds could not break freely. This induced me to try tying the Vines to the trellis before they were started and letting them remain there, and I can assure "H. H." if he will try this he will find no difference in breaking of buds between the Vines tied up and those bent down.—A STUDENT.

TUBEROUS ROOTED BEGONIAS.

THERE are, I think, but few plants so valuable for conservatory or garden decoration as the tuberous Begonia. The plants are generally raised from seed, and the time for sowing must be determined by the time at which the plants are expected to bloom. Seeds sown in February will generally afford plants that will flower about June. Use well drained seed pans filled with a compost of loam, leaf mould, and sand in equal parts, finishing with half an inch of the same finely sifted for the top, making the surface smooth and even.

The seed should be sown thinly and covered with the finest soil, placing the pans in a temperature of 60° to 65°. Cover with glass, over which place a thin layer of moss or some thick paper. As soon as the seedlings appear they must be gradually exposed to the light, and eventually placed on a shelf near the glass, where they should be shaded from the sun till the young plants become hardy and able to bear the full light. When seedlings are large enough they must be transplanted about an inch asunder in pans, and when well established they may be transferred to small pots, and subsequently into larger ones as required.

Use well drained pots, and a compost as follows:—Sound loam two parts, fibrous peat one part, leaf mould one part, well decayed cowdung half a part, and a small addition of silver sand. Do not allow the plants to suffer by want of water when they are growing freely. As the season advances gradually reduce the water supply, and as the stems begin to wither allow the soil to become quite dry. Clear soot water is a good stimulant during the flowering period, and an occasional supply of weak liquid manure may also be given. Always keep the plants free from insects.

When resting, the tubers may be allowed to remain in the pots, which ought to be laid on their sides to prevent the tubers getting wet. They will also keep well when placed in boxes filled with cocoa-nut fibre. The temperature in which they are resting ought not to fall below 40°. They should be allowed to start into growth before repotting, when if a larger supply is in demand they may be divided and the cut fleshy parts dressed with powdered charcoal. They will also root freely from cuttings taken and inserted in small pots placed in a gentle bottom heat.—J. F. D.

CONSERVATORY MANAGEMENT.

(Continued from page 123.)

HAVING completed all necessary preparations hybrid Azaleas, which will now (April) be coming in flower. These, together with Deutzia gracilis (a number of which should have been steadily coming on), form a charming display. Many plants of Cytisus and Cinerarias will still be serviceable. Arum Lilies, Freesias, Imantophyllums, with Acacias armata and Drummondii will all be in bloom about this time, and help to complete the floral collection. Of the smaller plants for edging Sedum Sieboldi variegatum, Isoplepis gracilis, Funkia undulata argentea, F. undulata aurea, grown in 6-inch pots; Cyclamen, Primulas obconica and floribunda are all very useful. Hyacinths and other bulbs which have been kept in cold frames will still be available. Perhaps at no other season will the house appear so gay as now. Admit air freely when weather permits, and a light shading should also be afforded on bright days, in order to keep the flowers fresh as long as possible. Large bees are generally very troublesome at this time, and should be kept down, or they will do damage by causing the Azalea blooms to fall prematurely. A muslin net tied to the end of a long stick is very useful for catching the bees. Very little fire heat will now be required in the daytime, but warmth should be kept in the pipes on account of frosty nights.

In May the same collection will continue to beautify the house. Artificial heat may now be dispensed with, and shading afforded. Ventilate freely, and damp the floor about midday. By the end of the month the Azaleas and Deutzias will be ready to be removed. Pick off the old flower stems from the former, being careful not to injure the young growth in the operation. They may then be stood in a greenhouse, keeping it rather close until growth is complete. Syringe twice a day. A light top-dressing with Standen's manure will be beneficial. Deutzias may be similarly treated until growth is matured, when they may be

plunged in an open place where it will be convenient to cover the pots with leaves or old Mushroom bed refuse when the frost returns.

When the plants which have finished blooming have been disposed of attention should again be paid to the climbers. Clean the house thoroughly, when it will be ready for the succession of Pelargoniums. These plants having been finally potted in March, or April at latest, in a compost of rich loam with a little charcoal added, should now be flowering, with *Lilium Harrisii*, *Malmaison Carnation*, *Spiræa japonica* and *astilboides*, together with many of the smaller plants left from the previous collection. Herbaceous *Calceolarias* raised from seed sown in June will also be in bloom now. These make an effective group arranged with *Adiantum cuneatum*.

This collection will monopolise the house until the middle of July, when they will have completed their work. The Pelargoniums should then be stood in an open frame to ripen their wood, when they may be cut back, leaving one or two eyes on each shoot, from which the new growths will start. Water should be given rather scantily until growth commences. When the young shoots are about an inch long the plants ought to be shaken out and placed in smaller pots. A compost of good loam with a little sand and charcoal added will suit them very well. They may then be removed to a cool greenhouse, and care taken in watering until the plants are well established. When the growth is about 3 inches long take out the points to insure bushy plants. An occasional top-dressing with Clay's fertiliser will greatly assist them until they are finally potted as previously stated.

Having suitably disposed of all other unnecessary plants, the opportunity should again be taken to do all requisite cleaning preparatory to the house being again arranged with the next succession.—P. W.

(To be continued.)

[We shall be much obliged if all our young friends will, as the majority do, write their names and addresses at the top of their MS., not on separate slips or in private letters. Marks of merit are accorded for every article, and duly entered in the register to the names at the head of each MS. We should also like every writer to do what all the best of writers do—namely, write every word in full that they intend to use. Abbreviations are defects in literary work. We have other notes in type, and we wish it to be understood that it is not the rule to publish the best first.]

FRUIT FORCING.

Cherry House.—The temperature being maintained at 40° to 45° at night, and about 50° in the daytime regularly, the trees rapidly unfold the buds, especially when the weather, as it has been recently, is mild. Before the flowers expand it is desirable to fumigate the house, as aphides are very partial to the tender growths of Cherry trees and almost certain to be present; or by syringing the trees with an approved insecticide make sure the trees are free from the insects. The liquid, however, must be clear and not injurious to Cherry blossom, which is easily damaged or discoloured. Rather strong quassia water (4 ozs. chips to a gallon of water, steeped overnight and boiled a quarter of an hour) answers well, repeating at intervals of a day or two. Though a Cherry house, especially for early forcing, may only be found here and there throughout the country, no structure affords more acceptable fruit for dessert in the late spring or early summer months.

But few varieties should be grown for general purposes, three excellent being Early Rivers, Governor Wood, and Black Tartarian. A lean-to house erected against a wall with a south aspect is suitable, and it need not be more than 6 to 7 feet 6 inches in width. The front need not be more than 2 feet 6 inches in height, so that the roof will be a long one, and facing the sun at a desirable angle for admitting light. Ventilation should be provided at the top and bottom, and the roof lights must be moveable. A trellis 9 to 12 inches from the glass will be needed to secure the trees in proper position. Fan-trained trees with stems just reaching to the trellis are most suitable. Two rows of 4-inch hot-water pipes (a flow and return) will afford sufficient heat. The border must be inside, though the roots may also have access to the outside, and thoroughly drained to carry off superfluous water. Good loam, preferably calcareous and rather strong, but with a free admixture naturally or artificially of gritty matter, is most suitable. Trees from the open wall between three and four years trained, if carefully removed to the house, come into bearing at once; but to insure success they must have been frequently lifted. Supply water to settle the soil about the roots, and ventilate the house freely, syringing the trees in the morning and again early in the afternoon, employing fire heat only to exclude frost; but when the trees are fairly in growth let the day temperature from fire heat be 50° to 55°, rising to 60° to 65° from sun, increasing the ventilation at 55° and close at that temperature, leaving, however, a little ventilation on day and night; 40° to 45° at night from artificial heat will be sufficient.

Cucumbers.—The plants require a steady temperature and genial atmosphere, the bottom heat 80°, not allowing it to fall below 75° or exceed 90°; top heat 65° to 70° at night, 5° less in severe weather; 70°

to 75° by day, rising to 85° or 90° with sun, closing early in the afternoon, so as to run up or maintain a temperature of 90°, 95°, or 100°. Examine the plants in bearing once a week for the removal of bad leaves and exhausted growths, not allowing them to remain, but thinning the shoots—the young to prevent crowding, and the old to allow of training-in young growths. Stop one or two joints beyond the show for fruit, removing old and deformed fruits, as they do nothing but impoverish the plant. In securing the young shoots to the trellis do not tie them too tightly, but allow room for development. Plants that have been in bearing some time should have the surface soil removed, and previously warmed fresh soil added. Turfy loam, with a fourth of well-decayed manure, will answer; but to get colour into the fruit, without which they are faulty for marketing, sprinkling a good handful of soot on each square yard. Native guano is also an excellent dressing for promoting high colour in fruits. Damp the pathways on bright mornings and early in the afternoon, keeping the evaporation troughs charged with liquid manure—neat stable draining diluted with five times the bulk of water, or Peruvian guano ammoniated, 1 lb. to 20 gallons of water.

Cucumbers in frames must be well protected at night with mats or other covering, attending to the linings, and being careful to avoid rank steam, having the materials well sweetened, a reserve heap of manure and leaves, properly turned, being kept for use as required.

Figs.—*Earliest Trees in Pots.*—The trees having a number of fully developed leaves and the roots active they will require a proper supply of water and nourishment. Turves may be placed around the rims of the pots so as to form a dish, and this sprinkled with rich compost as the roots occupy it is better than giving a heavy top-dressing all at once. Liquid manure in a weak tepid state must be given as required, and always in sufficient quantity to pass through the soil to the drainage. The atmosphere must be kept moist, syringing the plants twice a day when the weather is fine, and damping the walls and paths when dull, for having the foliage constantly wet is not favourable to the tree's health. Keep the temperature steady at 60° at night, falling 5° on cold nights, 60° to 65° by day when cold and dull, and 70° to 75° with gleams of sun. Admit a little air at 70°, keeping it with sun heat at 75° to 80° through the day, closing sufficiently early to run up to 85° or 90°. Attend to stopping and tying as growth advances, and guard against overcrowding by rubbing off shoots not required. The shoots should be pinched at the fifth leaf, and as the branches may not always be thinned without sacrificing fruit advanced in swelling, tie such out, putting in the needful stakes. The shoots are easily cut out, if not required, when the fruit is gathered, and it is essential that Figs have full exposure to light and a free circulation of air to insure flavour and colour, therefore keep the growths thin and evenly placed.

Early Forced Planted-out Trees.—The trees started with the new year are growing freely, and must be attended to for disbudding and stopping. Where there is trellis room the leading shoots may be allowed to extend to the extremity without stopping, not laying in more than there is room for insuring full exposure to light, reserving a few growths where there is space, pinching them at the fifth leaf. These will give second crop Figs, and may be useful for displacing shoots later that are cut away, but it is not good practice to encourage spur-growth. Mulch the border with lumpy material to attract the roots to the surface, and supply water freely, with liquid manure in the case of trees requiring support through limited rooting area. A temperature of 55° to 60° at night, 60° to 65° by day artificially, 70° to 75° with a little sun, rising 5° to 10° from bright sunshine, will be suitable.

Late Houses.—The pruning and dressing of the trees should be completed without delay, using a brush and soapy water to cleanse them of scale, adding a wineglassful of petroleum to each gallon; but to secure an even mixing dissolve ¼ pound softsoap in a quart of water by boiling, and when boiling add the petroleum, removing from the fire for safety, and stirring briskly. Dilute to 1 gallon with hot water for use. Keep the house as cool as possible, merely excluding frosts.

Strawberries in Pots.—After being fairly set remove all badly set and deformed fruits, leaving from four to half a dozen of the more promising to each plant, and aid their swelling by liquid manure. The temperature should be 60° to 65°, advancing to 70° or 75° by day with moderate ventilation. Avoid drying currents of air, as they injuriously affect the swelling of the fruit. Examine the plants twice each day, giving water to those only needing it, and in sufficient quantity to show at the drainage. See that succession plants are kept free from aphides, fumigating if necessary before the flowers open. British Queen and other sorts for a late supply may now be started, introducing, however, proportionate quantities of Sir Joseph Paxton and similar varieties to maintain the succession.

THE KITCHEN GARDEN.

Early Peas.—About the middle of February is a good time to sow the early round-seeded Peas, such as William I., Exonian, and Eclipse in the open, but heavy soils will not as yet have recovered from the saturation they have had lately, and to puddle in any kind of seed is only to invite failure. Better wait a fortnight longer than do that. In any case keep the more tender, wrinkled seed in the bags a while longer, as these are most liable to decay in the ground if sown before it is fit for their reception. From a pint to a quart of seed sown in "Geranium" boxes under glass in gentle heat would give enough plants for forming a row or rows equal to a length of 60 feet, and if put out before the roots become matted together little or no check would be caused to their progress, and excellent early crops obtained. Plant on warm borders in due course, and take the first favourable opportunity,

this being when the ground works freely and does not bind badly when trampled on, of sowing seeds in the open by way of succession.

Spinach.—It is the usual practice to sow Spinach at the same time as Peas, arranging the rows midway between the latter. This plan answers well, the Spinach attaining a serviceable size before the Peas unduly shade it. Open shallow drills, and sow somewhat thinly. The autumn sown Spinach has withstood the frosts well, and with a return of sunshine and dry warm weather growth should be strong. On a dry day hand-weed between the plants where needed, and use the Dutch hoe between the rows, raking off the weeds, or otherwise they will rot afresh.

Broad Beans.—Much that has been advanced concerning Peas also applies to Broad Beans, the seed of choicer varieties of these being also liable to perish in a cold wet soil. If wanted extra early sow the Early Longpod in small pots, and plant out before the plants become stunted in growth. This variety and the popular Beck's Dwarf Green Gem may be sown on warm borders or in a well-prepared sunny open site directly the ground can be got into a suitable condition. Open single drills 2 feet apart and 2 inches deep, dropping in the seeds somewhat freely to allow for failures.

Cabbage.—Few or no plants have been injured by frost, slugs proving the worst enemy to them. It will be found that most of the plants have been partially upheaved by the action of frost, and they will not make good progress, many probably bolting unless refixed. A frequent use of the Dutch hoe is one of the best preventives of slug increase, and otherwise acts beneficially. Fill up gaps in the rows of Cabbage plants with others from the nursery or seed-beds, moving those that have been previously pricked out with a trowel, a ball of soil about the roots being essential in this case.

Garlic and Shallots.—If these are kept out of the ground till they have sprouted badly a partial failure is likely to occur. Directly the soil, previously manured and dug, is dry enough to walk upon without binding seriously, make it fine to a depth of at least 4 inches without bringing up lumps of wet soil from below, at the same time stirring in soot by way of a manurial dressing. The rows across the border to be 1 foot apart, and the bulbs 6 inches apart in the rows. Press them in, only the neck showing above the soil.

Parsley.—The principal breadth of Parsley may well be associated with Garlic and Shallots. Drills may be drawn midway between the rows of the two latter and Parsley seed sown, or better still, the requisite number of plants raised thinly in boxes or beds of soil in heat, and these, after being duly hardened off, dibbled out singly, from 9 inches to 12 inches apart. Parsley can be had much the quickest in this way, and grand plants form before the end of the season. The Garlic and Shallots will be ready for clearing off long before the whole of the ground is required by the Parsley.

Parsnips.—February has long been the popular month for sowing Parsnip seed. If extra large roots are desired early sowing is advisable, but not if the necessarily deeply dug ground is in a sodden state. Better wait a fortnight or three weeks later, sowing the seed when the ground is in a fit condition to receive it. If the ground was heavily manured for a preceding surface rooting crop none ought to have been dug in for Parsnips, and the least that can be done is to bury solid manure not less than the full depth of the spade, an early contact of the tap roots with animal manure causing them to fork. For cooking purposes small roots are much to be preferred, and these will be more surely obtained by sowing a month or six weeks later.

Turnips.—Early Turnips are always of good service. If not as a dish they are almost indispensable for flavouring soup. The Early Milan is the quickest to "bulb," and an east border is the best position for sowing. Let this be freely manured, and got into a fine firm condition. Sow the seed in shallow drills 12 inches apart. A close look out to be kept for the seedlings, and directly they appear dust over heavily while the dew is on them with soot and lime by way of preventive of bird, slug, and flea attacks, repeating this as often as need be.

PLANT HOUSES.

Crotons.—Well-furnished plants that are to be grown to a larger size may be transferred into pots 2 inches larger than those they now occupy. In potting only remove the crocks from the base and loose soil from the surface. Well furnished heads of the larger growing varieties may have pots 8 inches larger than those they are growing in. Plants that have good heads but have become bare at the base may be partially cut through on each side, mossed, and supplied with a stake. These if kept moist and with those that are repotted in a temperature of 65° at night will soon be well rooted. Those mossed in early autumn are well rooted and ready for taking off. If these are placed into 5-inch pots and plunged in bottom heat for a fortnight they will not lose a single leaf, and in a short time will be ready for larger pots. If these plants are increased by means of cuttings they may at this season of the year be cut off where the wood is soft, or they will be a long time rooting and often lose their lower foliage. These plants do well in fibry loam three parts, the other portion being composed of decayed manure, leaf mould, and sand. A little artificial manure may with advantage be mixed with the soil.

Dracaenas.—It is impossible to grow these into good plants if they are confined in small pots until they become stunted and woody. If they are to be developed into healthy well-furnished specimens they may be potted directly the soil is moderately well filled with roots. Those placed during September into 5 and 6-inch pots are ready for others 2 inches larger. The pots at first appear too large for the plants, but they will commence rapid growth, and develop into large well

furnished plants in this size. Some of the narrow leaf varieties do not need such large pots, and are generally more useful in 5 and 6-inch size. Plants that have become bare may have the stems notched and mossed; these soon emit roots, and are in a few months suitable again for table decoration. Plants that have been kept rather dry may have the root portion of the stem cut up for stock. Every portion will make a plant if inserted in sandy soil and started in brisk heat. These plants, if well looked after, are amongst the easiest of foliage plants to grow, and amongst the most useful for decorative purposes. The heads of *D. gracilis* and *D. Goldiana* root freely if cut off where the wood is moderately soft, and the pots plunged in brisk heat.

Pandanus Veitchi.—Repot small plants in a mixture of loam, sand, and one-seventh of manure. These are useful in various sizes up to 10-inch size. When plants are well developed all the suckers are removed for stock, and the specimens are employed for decoration until they are of no further use. When once a stock is obtained there is no difficulty in growing young plants as rapidly as others are destroyed. For rooms, or even the dinner table, these plants look well rising from a base of Selaginellas and small Ferns. When giving the final potting a few may be placed on the surface. By the time the plants are ready for use the base will be well furnished.

Ixoras.—Large plants, or those of moderate size, may be cut into shape and thoroughly cleaned. These may then be plunged in bottom heat and started into growth. By cutting the plants back the whole of the shoots start into growth about the same time, and a regular head of bloom is obtained. When the plants have started into growth any potting that is needed should be done. The old ball must not be disturbed, and the plants may be potted in peat and sand with a little charcoal added. Considerable care is needed in watering and syringing. Any young shoots of moderately soft wood can be inserted singly in small pots and rooted in brisk heat in the propagating frame. These can be allowed to grow and flower in 4-inch pots. If needed for bushes the point must be removed when the cuttings are well rooted. Those inserted in autumn and have been wintered in 2½-inch pots may be topped and placed in 5-inch pots. It is a good plan to top some and allow the others to grow on without, so that they will form a succession.

Rondeletias.—These are difficult to grow into fine specimens, yet with care and good treatment this can be accomplished. They yield flowers freely, which are very serviceable for cutting, and should be grown much more largely than they are. The plants are slow in a young state, and much headway cannot be made in a solitary season. Cuttings of soft wood root freely in sandy soil under bell-glasses in brisk heat. This plant may be grown into bushes or small standards; for the latter the young plants, after they are rooted, must be supplied with a stake and allowed to extend until the necessary length of stem has been produced, when the point should be removed to induce it to branch. For bushes the young plants may be topped when they have made a few inches of growth. Pinching is necessary until the plants have formed good bushes, when the shoots may be allowed to extend and ripen thoroughly, when every one will produce a truss of bright scarlet flowers. To grow these plants well they may be grown with *Ixoras*, and if given bottom heat they extend much more rapidly during the early stages of their growth. *Rondeletias*, of which *R. speciosa* major is the best, are not strong-rooting plants, and do well if potted the same as *Ixoras*, and in similar compost. We have been successful with them when one-third of sandy loam has been incorporated with the peat. These plants are much subject to thrips, and need careful watering. When bushes or standards have been formed they can be kept shapely by a judicious system of cutting back the shoots after flowering.

Francisceas.—Introduce into brisk heat a few of these plants in succession as they are required in bloom. When they have flowered cut back the shoots and start them into growth, repotting those that need more root room. They succeed in a compost of peat, loam, and sand, and when the plants are growing freely an intermediate temperature is suitable.

THE BEE-KEEPER.

APIARIAN NOTES.

WILL "An English Bee-keeper" kindly explain the following which I have taken from the last issue of *Journal of Horticulture*? "All sections of comb honey should be properly sealed over, and if glazed it will prevent them being damaged when handled." When sections are properly sealed is there a composition for glazing that will prevent the honey from leaking? I should be extremely obliged for any information on the subject. I have only just commenced with bees, and find there is much to learn.—B. C. N.

GLAZING SECTIONS.

When sections of comb honey are glazed it is a great protection from damage whilst being handled. It will at once be seen that sections treated in this manner cannot possibly come to any harm unless the glass is broken, and this will only happen if roughly used.

There is no composition that will prevent the honey leaking if it is not well sealed over, from the fact that the comb is not

interfered with, but if the operation is properly carried out there cannot possibly be any leakage. The glazing of sections, however, adds to the expense, and unless an extra price can be made of them in that form I do not recommend it for general use. In some districts it is rarely done, but in the South of England it is much more frequent.

Mr. W. Woodley, Beedon, who has one of the largest apiaries in this country, obtains the bulk of his surplus in sections, and is a warm advocate of glazing them. He says, by going to a glass merchant and ordering a few gross of glass cut $4\frac{3}{8}$ by $4\frac{3}{8}$ (if cut to this size there will be no trouble with sharp corners sticking through the paper), the price will be about 2s. 6d. per gross. To this must be added lace paper, which is specially made for that purpose, and may be obtained of dealers at a cheap rate (about 4s. per 1000 strips).

In the operation of fixing rest the section of honey flat or slanting to suit the convenience in handling, lay on glass, and then gum the paper strip (cut to 17 inches), fold it round, and then turn it down. With a little practice perfection will soon be arrived at. Some use thin glue, others strong paste; possibly stickfast may do well for the job.

The above query, emanating as it does from a good gardener, is encouraging, showing the growing interest that is being taken by gardeners in bee-keeping.

PACKING SECTIONS OF HONEY.

This requires more attention than is usually given to it. The mistake so many people make is in not packing firmly enough. If sections and glass jars of honey are packed in the same box (which is not a good plan) there should always be a strip of thin wood or stout cardboard placed between them, which will prevent the comb being damaged. That a warning is necessary I am convinced, as quite recently I received a package containing a glazed section and a jar of honey which, owing to bad packing, the section of honey was smashed, whereas had there been a thin strip of wood between the jar and the face of the section the latter would doubtless have arrived in as good condition as when first packed.

In sending honey by rail it is not necessary to send it by passenger train, or to label it, "Glass, with care," as is often done, or double rate will be charged. If well packed it will travel equally well by goods train. Of this I have proof. A few years ago I had several dozen sections that I was anxious to exhibit at a provincial show at which royalty was expected. They had only been taken off the hives a few hours before being sent off, and were unglazed. These were firmly packed in boxes in the same position as they occupied in the hive. Across the ends were placed a double thickness of stout cardboard, and between this and the end of the box, also between the ends of sections and the sides of box, rolls of newspaper were well wedged in, a double thickness of paper was placed over the top of sections, and then another layer of sections as before. Each box contained about five dozen sections, and was nailed and corded in the usual manner. These were addressed to the Bee Department of the show, and labelled, "Honey, with care." After being jolted for several miles over a rough country road they were eventually dispatched by goods train. A few days afterwards, on my arrival at the show, I found my honey packages awaiting me, not a section of which was damaged. These were all disposed of at what we should now term fancy prices.

Since then, when sending sections to tradesmen I have adopted a different plan, which is to be preferred to the above, for unless care is taken in unpacking they may be easily damaged. First of all take a piece of stout paper, or a double thickness of newspaper. On this place six sections; at the ends put a piece of cardboard about 6 inches square, this will allow the edges to be turned over the ends of the sections, and prevent their moving. Wrap the paper tightly round them and tie with string. Place a mark on the outside of package to show which is the top of sections. Continue to make as many packages as are required, then take a box—a Tate's cube sugar box will answer the purpose admirably—place a layer of soft hay over the bottom of the box, on this lay the packages of sections, then another layer of hay and sections till the box is full. Over the top layer of sections place more hay until the lid fits closely to it. All the spaces round the sides of box should be packed with the same material. The lid should be securely fastened down, and the box corded. There is no necessity for the latter if before the box is packed a couple of holes are bored at each end of the case, so that a stout rope can be inserted for handles.

If carefully packed on the above lines, and marked "Honey, with care," sections may be safely dispatched by goods train without any serious risk of damage. Care must be taken to place the sections in the same position they occupied in the hive. It is a good plan to put a mark on the top of the sections when removing them from the hive. It will save a great amount of unnecessary trouble afterwards.—AN ENGLISH BEE-KEEPER

•• All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Addresses (C. S. N.).—A post-card has been sent to you giving the desired information. If it fail to reach you please send a more complete address.

Pruning Maiden Apple, Pear, and Plum Trees (W. W.).—For pyramids cut them down to within 15 inches of the ground or 1 foot from the junction of stock and scion to a good bud, so as to secure a strong leading growth. If the Plums have any side growths shorten them to two or three buds, leaving most at the lower part and fewest at top—pyramid shape. Single oblique cordons will not need any pruning, and must be cut off (except the terminal bud is a fruit bud), as at an angle of 45° they will push growths down to the base. If they have any laterals shorten them to one bud. For double oblique cordons shorten the trees to 12 inches, the uppermost bud left being on the low side and next below on the upper side of the growth when the trees are planted in their oblique position. On these two buds depend for shoots to form the cordons. Of the Apples, Lord Grosvenor, Warner's King, and Bramley's Seedling are the strongest growers, next them King of the Pippins and Cox's Orange Pippin, Ecklinville and Lane's Prince Albert in degree downwards. The last named is only suitable for very low cordons.

"Flights" (or Refuse from Carpet Works) as Manure (H. B.).—As a fertiliser it has a low nitrogenous value, but the substance has special importance where a slow decomposing manure is desired. "Wool waste" has long been used by market gardeners and Hop growers, and we used it nearly fifty years ago. The market gardeners and Hop growers like it because it is light, therefore easily portable, readily applied, can be dug in during winter operations, decomposes slowly, and therefore lasts a long time. It is, however, of very variable quality, sometimes not containing more than 1 per cent. nitrogen, many samples of so-called "wool manure" not being wool at all, but cotton, and practically worthless. "Flights," when of good quality, contain not less than 8 per cent. of ammonia, and the value per unit 5s. to 7s. 6d. Your sample appears to be good, and will act beneficially during the next three years, as its ammonia is yielded slowly. You say nothing as to the quantity used, which is a matter of importance. One to two tons per acre is the usual amount applied. As for its value as an insecticide that depends on the dye, which in your sample is aniline, prepared from benzole or benzene, one of the numerous products of coal tar, and consisting of hydrogen and carbon (C₆H₆). Benzole, acted on by nitric acid, produces nitro-benzole (C₆H₅NO₂), and this, again treated with nascent hydrogen, generally produced by the action of acetic acid upon iron filings or scraps, produces aniline (C₆H₇N). It will, therefore, have considerable insecticidal value. Mixed in the soil at the rate of quarter hundredweight per rod in the autumn it has, we are told,

acted beneficially against eelworm. That it will act well against grubs there is no reason to question; but as for clubbing, that depends on the form, for almost anything with a thickened root is termed "clubbed," no matter what the cause may be—eelworms, maggots, grubs, or finger-and-toe fungus. We shall be pleased to have the results of your experiments with "Flights," especially as we have seen the sample, if the amount used per area of land be given, and the crops grown on it stated.

Apple Jolly Beggar (*R. P. Jones*).—This useful variety (fig. 33) is very productive either as a bush tree on the Paradise stock or as a standard on the Crab; in fact, Dr. Hogg considers its great merit to be its extreme fertility, small bushes producing abundance of fine yellow fruit. He describes it in the "Fruit Manual" as a first-rate early cooking Apple from August to October, the tree bearing very

FIG. 33.—APPLE JOLLY BEGGAR.

early, and considers it to be one of the most useful varieties for garden culture. The fruit is firm, heavy, and keeps well. It is of about medium size, 2½ inches wide and 2 inches high; roundish oblate. Skin pale yellow, with an orange tinge next the sun, and strewn with russet dots. Flesh white, tender, juicy, sweet, briskly and pleasantly flavoured.

"Worm" Destroying Tomato Plants (*H. G. G.*).—The "very small worm with a black head" taken from the centre of a small Tomato plant reached us without the head, the frontal segments being crushed beyond recognition. We, however, know the creature well enough. It is the larva or "wireworm" of the smallest of the click or skip-jack beetles (*Elatér sputator*, *Fab.*), and eats its way into the seedling plants, being very fond of Tomatoes and Potatoes. It is also partial to young Carrots, and above all grasses, burrowing in their root stems. The mischief it works in Tomatoes is frequently not discovered until the plants collapse and are beyond remedy. The best thing we have tried against them is kailit, in bad cases, 7 lbs. per rod, 4 ozs. per square yard; and in ordinary cases of infection half those amounts respectively. For plants in pots we have used a quarter of an ounce to a pint of water, or 2 ozs. to a gallon, and placed small plants in a shallow vessel, such as a dripping tin or foot bath, and watered them with the solution, so as to make sure that the soil was thoroughly soaked through. Another plan and better, but more troublesome, is to stop the holes in the pots with a little tempered clay, and then water with the solution so that it stands or appears on the surface, allow to soak five minutes, then remove the clay from the holes of the pots. Soluble phenyle, one in 100 parts water, will also kill the wireworm. Tomatoes, however, root so quickly that we should not hesitate to turn the whole of the plants out, wash off the soil, and examine them for wireworm, removing the grubs, if any, and repotting in soil from a fresh source.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (*N. N.*)—Golden Winter Pearmain.

(*J. F. D.*).—Brabant Bellefleur. (*E. Semper*).—1, Brabant Bellefleur; 2, Winter Greening; 3, Adams' Pearmain; 4, Maltster. (*F. R. B.*).—1, Cox's Orange Pippin; 2, Bramley's Seedling; 3, Lady Henniker; 4, Beauty of Kent; 5, Wellington (Dumelow's Seedling); 6, unknown, probably a local seedling.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A. McM.*).—Most of your specimens were too small for positive identification, besides arriving in a withered state through inefficient packing; possibly they were—1, *Adiantum pubescens*; 2, *A. assimile*; 3, *Blechnum*; 4, *Asplenium flaccidum*; 5, *Asplenium Adiantum nigrum* or *Davallia canariensis*; 6, a *Blechnum*. (*K. W. G.*).—1, *Begonia manicata*; 2, *Zygopetalum Mackayi*; the *Cypripedium* is too poor a flower for anyone to give a decisive answer as to its name. We are uncertain of the foliage plant, please send specimen when in flower.

THE MANURE HEAP.

HOWEVER wisely the tillage merchant may charm, and however loudly agricultural science may preach as to the superiority of artificials over time-honoured muck, there are still numberless

farmers who have unlimited faith in its efficacy, and not without good reason, for good yard manure is beneficial to all crops, and has a bit of wear and tear about it that is lacking in these hand-to-mouth fertilisers. Still, muck has its drawbacks, the chief being the amount of labour entailed in the filling and carting of it to the land, especially if the field be some distance from the premises.

It is inevitable that manure will continue to be made and used, for cattle rearing and feeding is too important a part of British agriculture to be discontinued. It is very necessary, however, to get all possible benefit from the dung when it is made. Much has been done in this direction of late by the very general adoption of covered yards, but greater intelligence is yet required to fully utilise the liquids which in too many cases are allowed to escape into the watercourses before being deprived of the valuable manurial constituents which they contain.

We have heard it suggested that we should sell all the Wheat straw now used as bedding, and use peat moss in its place. The manurial value of the straw is about 8s. per ton, the selling value about 40s. As peat moss is a much more valuable absorbent than straw there is much force in the arguments in its favour, especially if the comfort of the animals is left out of consideration.

The low value of straw as an absorbent will be seen by a study of the appended table. It is noticeable that powdered peat is even more valuable than the moss, and that even peaty soil has a considerable value as a foundation for the manure heap.

1000 lbs. of Wheat straw will absorb	1 $\frac{3}{4}$ lbs. of ammonia.
1000 lbs. of sawdust	" $\frac{1}{2}$ lb. do.
1000 lbs. of peat moss	" 8 $\frac{3}{4}$ lbs. do.
1000 lbs. of sandy earth	" $\frac{3}{4}$ lb. do.
1000 lbs. of powdered peat	" 11 $\frac{1}{4}$ lbs. do.
1000 lbs. of limy earth	" 1 $\frac{3}{4}$ lb. do.
1000 lbs. of fresh soil	" 2 $\frac{1}{4}$ lbs. do.
1000 lbs. of garden soil	" 5 $\frac{1}{2}$ lbs. do.
1000 lbs. of peaty soil	" 6 $\frac{3}{4}$ lbs. do.

It would appear that whether we use peat moss litter as litter or not, we should put a layer of it or of powdered peat at the lowest part of our yards, also beneath and immediately around all heaps of moist manure. For cattle in stalls and boxes very little straw need be used, as they can be made quite comfortable with peat moss, which would absorb all liquids, and nothing would be lost. How important the preservation of this liquid manure is will be understood by a perusal of the following table, giving approximately the constituents of the manure and urine of the principal farm animals. The manure of the following four animals contains—

Per 1000 lbs.	Sheep.	Pig.	Horse.	Cow.
Nitrogen ...	7 $\frac{1}{2}$	4 $\frac{1}{2}$	5	3
Phosphoric acid ...	6	5	3 $\frac{1}{2}$	2 $\frac{1}{2}$
Potash ...	3	25	3	1
The urine contains—				
Nitrogen ...	14	3	12	8
Phosphoric acid ...	0 $\frac{1}{2}$	1 $\frac{1}{4}$	0	0 $\frac{1}{2}$
Potash ...	20	2	5	14

We see here that as regards two of the principal farm animals—the cow and the horse—the liquids are two and a half times as rich as the solids in nitrogen, that most costly of manures, whilst the value of the potash in the urine of cattle is very great indeed. Of course if this liquid can be run into a tank and afterwards distributed on the land by the aid of a liquid manure cart more powerful absorbents are not necessary, otherwise it seems certain that the use of peat moss as litter, either wholly or in part, must result in great saving of much valuable fertilising material. If straw can be sold at 40s. and peat moss bought at 25s. there is a margin of 15s. per ton in favour of the use of the latter, apart from the advantage gained in the greater absorption of liquids.

There are few large estates where real freedom of sale is allowed, but if agriculture in this country is to hold its own more freedom will have to be the rule rather than the exception. The best safeguard that a landlord can have against undue impoverishment of the soil is the possession of a good head of live stock by his tenant. As long as his stock is kept up to the mark

let him sell what he likes. If he can sell for 40s. something that he can replace for 15s. by all means let him do so; restriction in selling means restriction of power of rent paying, and is contrary to all mercantile principles.

We hold a very strong opinion that the amount of nitrogen that reaches the soil through the medium of farmyard manure under present systems is very small, and that the said manure owes more of its popularity to its phosphoric acid and potash than to its ammonia. It used to be a general custom to turn the manure heap soon after leading it from the yards, this prevented violent heating and loss of ammonia; but now we never see a man turning manure.

Unless we can take means to preserve the fertility of our muck, we had better get it spread on the soil as soon as made, for in winter there can be no loss from evaporation, and if spread on the ground thinly, none from heating. Much of the valuable constituents may be washed by rain into the soil, and that is where we want them to be.

WORK ON THE HOME FARM.

Frost, snow, rain, and flood succeeded each other in rapid succession, and farm work was much as it was last week. So far, little time has been lost; but unless we have finer weather for the remainder of the month work will begin to get into arrears, and they are always difficult to make up. The land is just getting free from frost, but though a plough would work it would not be advisable to begin again until the land is a little drier.

Many farmers are anxious to be drilling Oats, and naturally so after our experience of last harvest; the early bird then had the worm with a vengeance, all late crops being completely ruined. We had much better wait for a decent seed bed, however, as grain put in badly seldom—in fact, we might say never—does well. There is certainly nothing to be gained by sowing before March under present circumstances.

Turnip land should be ploughed up close to the sheep fold as soon as it is dry enough, and fallows may be crossed, but we would rather leave them alone for the present, unless it were on very light land in a foul condition, when time might be a matter of great importance. We would prefer to still give the horses a bit more rest, and keep all hands to repairing fences and drains, ditches and hedge bottoms rather than do harm by getting them on the land before it is fit; this only applies to medium and heavy soils. Very light, dry, and sandy land may be ploughed or worked any time.

We have had the lambing flock on Swedes for three weeks. They had previously got a little low in condition, and they required an extra forcing diet. They are now within ten days of lambing, and are coming off Swedes to Mangolds on grass. A few Oats and a little cotton cake given now until lambing make a great difference in the milking capabilities of the ewe, and are of much more use than given after lambing.

The use of drains has been amply illustrated to us during the recent flood. We had a field in process of being drained, and the quantity of water absolutely pouring down the pipes just put down was a revelation.

OUR LETTER BOX.

Wheat (E. M.).—If the Wheat is a good sample and the rick perfectly free from vermin—i.e., rats and mice—we should advise holding. The world's Wheat crop is deficient, harvest is far off, and we look and hope for a rise in price. If mice abound thresh at once.

REMARKS.

- 7th.—Bright sun in morning and frequently in afternoon; fine evening.
8th.—Slightly foggy generally, but faint sunshine about 11 A.M.; rain from 8 P.M. to 11 P.M.
9th.—Occasional drizzle early; mild fair day.
10th.—Fine and mild, with a gleam of sun at 1.30 P.M.; rain from 9 P.M.
11th.—Rain till 8 A.M., then dull, with drizzle or slight rain almost all day.
12th.—Overcast, but fair.
13th.—Fair early; frequent drizzle and rain after 11 A.M.
Much milder and rather damp.—G. J. SYMONS.

NOW READY.

**BARR'S
SEED GUIDE**For **1897.**

Barr's Seed Guide is full of practical hints, and is invaluable to Gardeners, Amateurs, and Exhibitors.

FREE TO INTENDING PURCHASERS.

VEGETABLE SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Select List of the Best Vegetable Seeds for securing a supply of Vegetables "the year round."

FLOWER SEEDS.

BARR'S ILLUSTRATED SEED GUIDE contains a Choice List of the best Seeds for the Flower Garden and Greenhouse.

ALL SEEDS CARRIAGE PAID ON RECEIPT OF REMITTANCE.

We guarantee all our Seeds to be of the finest selected strains, and of highest growing quality.

BARR & SONS

FOR SPRING PLANTING.

**COLLECTIONS OF VEGETABLE
AND FLOWER SEEDS,**

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM, HOLLAND, or to our General Agents,

Messrs. MERTENS & CO.,

3 CROSS LANE LONDON, E.C.

No. 870.—VOL. XXXIV., THIRD SERIES.

**Barter's
TESTED SEEDS.**A FEW MORE
New and Improved Vegetables.**CARTERS' OUTDOOR TOMATO.**

The very best for open-air cultivation we know of. Should be grown by everybody.

In Sealed Packets, price 3/6 each, post free.

CARTERS' LEVIATHAN BROAD BEAN.

The longest-podded Broad Bean grown; fine for exhibition, and one of the best for cooking purposes. We have seen pods 21 inches long.

In Sealed Packets, price 1s. 9d. per pint; 3s. per quart, post free.

CARTERS' RED ELEPHANT CARROT.

A veritable giant, both in length and rotundity. Specimens exhibited at our establishment measured 2½ feet in length.

In Sealed Packets, price 1/6 each, post free.

**CARTERS' EXTRA EARLY AUTUMN
GIANT CAULIFLOWER.**

This magnificent variety is more dwarf, considerably earlier, and altogether better than the old form. Grown in large quantities for Covent Garden Market.

In Sealed Packets, price 2s. each, post free.

CARTERS' SOLID IVORY CELERY.

Still maintains its position as one of the best white Celeries in cultivation. A customer writes:—"It was the only Celery we found good at the break-up of the intense frost."

In Sealed Packets, price 1/6 each, post free.

CARTERS' MODEL CUCUMBER.

Many so-called new Cucumbers are brought forward every season, but little is heard of them afterwards. This fine variety still maintains its position as the handsomest in shape, the best in flavour, and the finest in cultivation.

In Sealed Packets, price 2/6 and 3/6 each, post free.

CARTERS' RECORD ONION.

The largest Onion grown. A customer writes:—"I cleared the whole roost in the Onion competition with 'Record.'" We have seen a specimen bulb that weighed 4½ lb.

In Sealed Packets, price 2/- each, post free.

THE CARTER SPINACH.

Mr. A. PETTIGREW, Head Gardener to the Earl of Bute, writes:—"The best Spinach in cultivation; quite distinct from all others." Award of Merit, R.H.S. trials, 1895.

In Sealed Packets, price 2/6 per pint; 6d. per oz., post free.

Illustrated CATALOGUE, Gratis and Post Free.

TREE PRUNING.

TO the lover of trees, or rather with those whose love begets that sympathy which surpasses mere enjoyment, the fostering hand will never withhold the little attentions they require, nor will the critical eye fail to note those unhappy examples so frequently met with, proving, as they do, that "Poverty and Neglect sharpen the scythe of Time." Surely no more pleasing duty calls for an adequate share of the gardener's attention than that embraced by our subject. From observation, extending over many years, over a considerable area of the United Kingdom, with many peeps into private places, one is tempted to speak strongly upon a subject that is felt deeply. With all our vaunted progress in gardening in its broadest sense, are gardeners as a class taking unto themselves the full responsibility of this matter, or even feeling its weight? Neither the one nor the other I believe, and if not, why not?

On the one hand, we seldom find our experienced workers expatiating upon the matter beyond a passing notice of the subject in their descriptive notes, and so far as our budding gardeners are concerned, even this is yet conspicuous by its absence from their own special "domain" in these pages. Promising as those pages—"The Young Gardeners' Domain"—are of a bright future, this is not promising; I am inclined to say it looks bad, inasmuch as it is very undesirable that our young men, whose inclinations, judging by their writings, are warped to the glass houses or the flower beds, should develop a one-sided tendency. It would be a matter for regret, to me at least, if these remarks were regarded as a disagreeable potion, being simply compounded as a stimulant, which we should like to see operative with them. Not yet, perhaps, in a practical sense, but in something shown by their pens of an awakening interest in a subject which cannot but elevate their thoughts and widen their ideas, though still legitimately confined within the boundaries of their vocation.

We need not trench on "An Old Boy's" ground, from which will doubtless spring many hints to that end, but it is not too much to ask our young gardeners to diverge from the glass-

covered track, and take some little notes in their leisure hours of tree life in the locality; to detail the features of any notable examples, to tell us what they see, and what they think, may I add, upon the matter. One could then judge whether these pessimistic views are justified or not, whilst at present there is a lack of evidence to show that any thoughts on this subject are occupying their minds.

Ere turning to the practical part of our text I would ask young gardeners to contemplate the loftiness of our theme by referring to the remarks of a writer (unknown to me) upon the Wellingtonia, now so well known to us, in its infant stage. He says, "These mammoth trees of the Sierra Nevada for antiquity and size surpass all the vegetable products of the known world . . . Coeval with Solomon and David, there they have stood, and have continued to grow while kingdoms, empires, and dynasties have arisen and disappeared, and there they stand, the living patriarchs of 3000 years! These giant productions of the vegetable kingdom appear to average from 3000 to 4000 years; two of them (two lives) would, therefore, span the entire period of historical time, from the days of Adam to the present period?" Since the above was written it may, or may not, be qualified in some degree by more recent discoveries among the Eucalypti of Australia, in any case it cannot stultify our feelings of veneration and regard.

Another conclusion is, of course, clearly pointed—viz., that these particular trees have been very well able to take care of themselves, although probably they are the survivors of the fittest. It is, I grant you, a far-fetched example, but sufficiently near to our purpose I trust to draw our minds for the nonce from cherished, and rightly cherished, little things of plant life to our own indigenous trees, but few of which claim some simple attention, and to many of which such is absolutely necessary. From a long study of the subject I conclude that a very high percentage of those disasters frequently occurring in tree life are preventable by the "stitch in time." A few examples of the evil will serve to illustrate this. One is furnished by a grove of magnificent Silver Firs, the bulk of which had developed either twin or triplet leaders, possibly arising from a check to the legitimate leader in early life, but it had gone on unheeded until it was too late to mend. These trees being the noblest examples of their kind I have met with, they were as highly appreciated by many tree lovers who saw them in their prime, but within the space of one decade it was lamentable to see how many of them were laid low or disfigured by dismemberment. This was particularly the case with those having triplet stems, forming a handsome arboreal candelabra, with the side stem springing in a graceful curve from the main trunk about 10 feet from the base, and from thence of equal dimensions to the legitimate leader.

These trees were, I suppose, during the period of my observation just ripe for destruction either by wind or snow, and on one occasion at least the calamity proceeded from no other exciting cause than the moisture superimposed upon the foliage by an exceptionally still damp day, which brought the crack of doom. Noticing the disposition of these bastard leaders, springing at right angles from the trunk, whereby the whole weight is devoid of a basis of support, obviously this Nemesis of neglect must come sooner or later, generally later, and the later the larger the sacrifice. However, so these noble trees disappeared. With some fine and much-prized Tulip Trees considerable ingenuity was displayed in tying their limbs together with chains and iron bands, also a matter of considerable labour, and not quite satisfactory when accomplished. In both of the above instances the survival of the fittest pointed a forcible moral. These were those whose vigour and growth were concentrated in the single trunk, with the whole weight directly vertical. Needless to say they were shapely trees, well balanced, and in this case probably the result of accident; yet all those which suffered or came to an untimely end might by forethought have been prepared to withstand ordinary adversity.

Unfortunately, these things are not forced upon our notice till

late in life—tree life; but I have seen a great deal of laborious heavy saw-pruning carried out in the commendable anxiety to set matters right late in the day, all of which work forethought and the pruning-knife could have done in a moment infinitely better at the early stage, and at what a saving of arboreal vital force and energy. Respecting our indigenous trees the same moral applies in more or less degree. Many of them are disposed to lose their balance through mis-directed efforts on the part of one or more branches, which in their excess of strength leave an opening for mutilation at least. From a picturesque point of view some will not see the matter in the same light. We may safely say that there is but little danger of their being deprived of ample examples of their particular lines of beauty. The prostrate giant reclining on its elbows, those delightful forest peeps with trees growing *au naturel*, the Ivy-clad ruin of some noble tree; there is room for all, but a great deal more room for skilled arboriculture in those places we rightly look for it, and too often find it the one thing wanting.

The subject appears to be in direct relation to a gardener's duties. It does not concern the forester; his work is, practically, the production of timber, and moreover the methods of forestry planting are such as are conducive to the development of single, straight stems, leaving but little opening for the evils pointed out, and in any case no opening for my criticism. I trust the gardeners of the future will not only include this subject in their work but also make it a prominent one, and the chief onus of this is upon our young gardeners of to-day. Whether by rail or by road the necessity for it is continually forced upon me when criticising my neighbour's landmarks—his trees.

The saddest thing seen of late is the outcome of some burst of energy on the part of our county surveyor, by which miles and miles of trees condemned to exist by the roadsides are being hewed and hacked at by all sorts and conditions of men, except gardeners, resulting in unsightly stumps, splintered limbs, and in fact every possible kind of pruning to show how *not* to do it. This, however, if within the limits of our text is farther than I intended to go. There is, apparently, more work in hand for our County Council instructors, who more than probably have their hands full already. Yet the subject is one of national interest, for it concerns the public good.—SYLVA.

OUR HARDY PLANT BORDER.

(Continued from page 132.)

WALLFLOWERS.

NOTHING has yielded such good results in the way of fertilisers in the soil both for Wallflowers in the seed and the permanent beds as superphosphate of lime applied as a surface dressing at the rate of 1 oz. to the square yard, and raked in before planting, a sprinkling of nitrate of soda at the same rate as that named for the seed bed (quarter oz. per square yard) being given once after the plants have recovered from the transplanting. No other chemical manure or stable manure produced such vigorous and floriferous plants as this treatment; the flowers both in size and colour surpassed those from other plants, while the time of flowering was prolonged, showing that the plants had not been exhaustively stimulated.

Where there is sufficient space it is as well to allow the seedlings plenty of room at transplanting time. I am exceptionally placed as regards that, and in consequence a distance of 9 to 12 inches has been preferred, for the best results have been found to follow this liberal treatment. If strong, well-developed plants are not obtained before the final planting, a full measure of success must not be expected, and it is surprising what can be done with Wallflowers if the best attention be given to details that seem almost insignificant. It is not only to Wallflowers that this truth applies, for much of a gardener's success depends upon recognising the importance of details, and amongst many sentences worthy of remembrance in that remarkable little work, "Mushrooms for the Million," occurs the following, which was credited to the founder of the *Journal of Horticulture*. "In whatever you do either in writing or working, do not ignore the simplicities that bear upon your object, but attend to what are termed small matters. 'I promote,' said Napoleon, 'the man who is capable of mastering small details; any elephant can lift a hundredweight, few can pick up a pin.'"

The final transplanting of Wallflowers should be completed by the end of August or early in September, at least I have found that indispensable in a cold situation North of London. The plants must have time to recover from the check of removal before the winter sets in, and to insure this they should be lifted carefully with as little injury to their roots as possible, and when the soil is sufficiently moist to adhere to them in a compact ball. The warmth in the earth at that time is sufficient to encourage root action, and we then have our plants in excellent condition for the winter's trial which they pass safely even in severe weather, for few out of many thousands have been lost. They are allowed a distance of 18 inches apart when the plants are very strong.

There are other methods of raising a stock of Wallflowers for flowering later in the season, as seed can be sown early in the year (at the present time for instance) in cool houses or frames, and the plants so obtained can be placed out in March or early April; but the flowering is uncertain and irregular, some will flower in the summer, others in the autumn, and possibly some will flower during the winter in mild seasons, or they may not flower until the following spring. Such plants are useful where flowers for cutting are always in demand, but they cannot be relied upon for a general effect like those raised in May for flowering in the following year. Autumn and winter flowers will also be produced by some of the strongest of the spring plants if left undisturbed, and many a bunch of greatly appreciated blooms have thus been obtained through the dreary months when floral attractions were few out of doors. Cuttings are also easily rooted in early spring or late summer, but this method is only applicable to any varieties which it is desired to perpetuate in their true character, or to the double varieties, though these also are usually increased by seed now. Cuttings taken from the side growths about 3 inches in length, and inserted in pans, boxes, or prepared beds of sandy soil, kept shaded, cool, and moist, will form roots quickly, and can then be transplanted to be treated like the others.

So much attention has been paid to the selection and raising of Wallflowers by seed growers, that excellent strains are now obtainable from the best houses either mixed or in separate colours, and collections of double varieties are offered in eighteen different shades, while single varieties can be had in half that number of tints. Of distinct forms that have been dignified with special names and kept true to character the following have proved under my trial and observation to be the most worthy of note.

Single Varieties.—Dwarf Bedder, very compact and early, in two colours, yellow and reddish brown; Golden Tom Thumb, rich yellow, very dwarf; Cloth of Gold, very bright golden yellow, dwarf; Golden Beauty, also a fine dwarf type of a rich golden tint; Earliest of All, a good yellow, and very early; Harbinger, a well known early variety with bright red flowers; Primrose Dame, a clear primrose tint, dwarf; Eastern Queen, salmon red, very distinct and of good dwarf habit; Early Parisian, rich yellow, compact; Faerie Queen, a delicate pale clear yellow; Purple Queen, a warm purple tint; Ruby Gem, one of the best of the purple coloured forms, with a violet tint underlying the shining petals; and All the Year Round, a dark brown variety, of good habit and very floriferous.

But the two best for effective contrast, in masses or long lines, that I have tried are Blood Red and Belvoir Castle if first-class strains are secured, as can be done if a special request is made to any good seedsman. The Blood Red of the Covent Garden type is of medium height but excellent habit, compact, bushy, and sturdy; but the plants are taller than Belvoir Castle, to which they make a good back row. The flowers are the richest in colour of any known to me, and they also possess a powerful fragrance as compared with some of the varieties. Belvoir Castle is an excellent yellow, the colour is very pure, the habit dwarf, and the abundance of flowers produced by well grown plants is astonishing. The purple varieties and some of the other forms are interesting and attractive in themselves, but are unsuited for massing. The best fitted for this are those with well marked colours, and the shades of yellow and reddish brown harmonise admirably.

It only remains to add that our Wallflowers have proved one of the most attractive features of our border and garden, and this must be the excuse for saying so much about such a simple plant. —A COUNTRYMAN.

(To be continued.)

VIOLAS FOR THE GREENHOUSE.—One of the best uses that many varieties of Violas can be put to is pot culture. Plants from the frame that were put in as cuttings in October should be placed four or six plants around a 6-inch pot, using some good soil and standing them in a cold frame till March. Then transfer them to a cool greenhouse, keeping them near the glass, and they will throw fine potfuls of their chaste flowers. Violas at this time are much appreciated. We grow hundreds of pots every spring, and they are greatly admired.—S. J.

FLOWERING TREES AND SHRUBS.

DECIDUOUS.

(Continued from page 140.)

ON a bright spring day, when Nature is clad in her freshest garb, how brilliant in appearance is a mass of flowering Broom! The common yellow form (*Cytisus scoparius*) may often be seen in full splendour upon some wild British heath. We see it sometimes in our gardens, but usually in very small patches; yet there is many an unsightly bank which might be made attractive throughout the year by simply planting upon it in one bold mass of this easily grown *Cytisus*. *C. scoparius grandiflora* produces larger flowers than the older variety, and should, therefore, be

FIG. 34.—*DEUTZIA CANDIDISSIMA FLORE-PLENO.* (See page 154.)

reserved for the most prominent positions. *C. albus* and *C. purpureus* are excellent for planting near or upon a rockery for the sake of giving variety; but for large masses the yellow Broom is, I think, the best. That grand variety of *scoparius* named *Andreas* is perfectly distinct from any other form of the species, the brown and yellow markings of the flowers forming a delightful combination of colour. Fortunately the plants grow freely, and may now be obtained at a cheap rate. They are sure to be largely planted in the future.

The deciduous *Daphnes* are really attractive early flowering shrubs; I have frequently cut showy and deliciously scented sprays of *Mezereum* in January from plants growing in the open air. In planting a sheltered position should, if possible, be selected, in order to take the fullest advantage of its early flowering tendency. The so-called white form I do not care for, but *M. atro-rubrum* should be grown by all.

Deutzias seem to be more generally grown in pots than in

shrubberies, yet there is not the slightest reason why they should not be included in every large collection of flowering shrubs. No one, I think, will deny their great beauty when in flower. Some years ago I saw a good mass of *D. gracilis* flowering grandly in the grounds at Linton Park, near Maidstone; since that time I have seen it growing in a variety of situations, and in each instance it appeared to be quite at home. A sunny position should, if possible, be selected to insure well ripened wood. A mass planted on rising ground, with a few dot plants of *D. scabra*, *D. candidissima* flore-pleno (fig. 34, page 153), presents, when in flower, a chaste combination of fresh green and pure white; such a sight, indeed, that when unexpectedly encountered it invariably elicits a spontaneous expression of admiration. The Forsythias are very pretty yellow flowering shrubs, which display their charms in March and April; they are often employed for covering walls or fences, but are especially valuable for planting in shrubberies or on banks. *Suspensa* and *intermedia* are the most showy varieties.

We have comparatively few shrubs that flower during July and August; one is, therefore, tempted to wonder why *Hibiscus syriacus* (*Althæa frutex*) is not more frequently planted. They are both beautiful and uncommon in appearance, grow rapidly and thrive well in a rather light soil. A few years ago there were several fine specimens in the shrubberies at Preston Hall in Kent. The grounds there are well stocked with flowering shrubs generally, the majority of them having imperishable labels attached, a practice which might with advantage be followed in other gardens. A few of the best varieties of *Hibiscus* are *albo-luteolus* plenus, *albo-plenus*, *bicolor hybridus*, *carneo-plenus*, *elegantissimus*, *Ranunculiflorus*, *violaceus variegatus*, and *rubra plena*.

The culture of *Hydrangeas* has for years received a considerable amount of attention. This is not a matter for surprise, considering the enormous heads of showy flowers they produce. The plants are well adapted for sunny position in the front of shrubberies, for the mixed flower border, or for planting in beds. The latter is a plan not usually followed, but it is well worth trying. *Hortensis*, *H. japonica*, *Thos. Hogg*, and *paniculata grandiflora* are each good varieties to grow. The last named is the most recent addition, and one of the best.

I have often thought that if the *Hypericums* were stove plants which required a great amount of attention their good qualities would be much more frequently proclaimed, but by a peculiar process of reasoning—in which logic plays but little part—the majority of writers seem to arrive at the conclusion that they ought to be ignored because they happen to be easily grown hardy plants, which will thrive and clothe with surpassing beauty odd nooks when other things refuse to grow. *H. calycinum* is one of the very best dwarf shrubs for planting on dry banks, or as a fringe to shrubberies bounded by walks or drives. An open sunny position suits this Rose of Sharon the best, and when such can be given it the plants quickly grow into a dense mass. In the early days of summer each shoot is crowned with a golden starry blossom, and when large breadths are grown the scene is then one of the most brilliant to be met with in a garden. *H. Moserianum*, *H. M. tricolor*, and *H. pyramdatum* are also good varieties, not so well known as the first named one.

For growing against a wall or in the form of a bush *Kerrias japonica* and flore-pleno are very attractive shrubs. The orange yellow colour of their flowers is one not plentiful in other hardy plants during March and April. The only attention necessary in the way of pruning is to remove dead and worn-out shoots each year.

Of the charms of *Laburnums* I need say but little, as they are so well known by all, or perhaps I should say, by all who live beyond the bounds of smoky towns. To those who have the management of large shrubberies I should like to suggest that there may be few positions where *Laburnums* may yet be planted with a distinct gain in regard to effect, for I do not remember to have seen a garden in which they were too plentiful. Some of the best forms of *Laburnum* are *alpinum* (Scotch), *vulgare*, *v. giganteum*, *v. Parkesi*, *v. Wateri*. The last named is an exceedingly good variety of *vulgare*, bearing flowers in very long racemes. The colour is also extra bright.

Magnolias require a separate article to do them full justice, but for the benefit of intending planters I will enumerate a few of the best varieties, all of which are included in our collection. *M. conspicua*, the well known white variety, more generally grown than any other; *c. Soulangeana*, *c. S. nigra*, *glauca*, *purpurea*, *p. Lenne* and *stellata*. The latter has small flowers, and the habit of shrub is very dwarf.

The old variety of *Philadelphus coronarius* has by far the sweetest scent of any, and is, therefore, still worthy of being planted. Many of the newer varieties, however, have more showy flowers. *Grandiflorus* is, I think, the best among the taller-growing

ones, and *macrophyllus* occupies the post of honour among the dwarf bushy ones.

Although the number of species and varieties of *Prunus* grown for ornamental purposes is not large, they nevertheless include several which may be termed "gems" among flowering shrubs. These are:—*P. Pissardi*, which produces a profusion of white flowers in March, and the leaves when fully developed are of a rich reddish-purple colour; *P. sinensis flore-pleno*, and a rose-coloured variety of it, both of which are dwarf in habit of growth. *P. triloba* is quite worthy of the protection of a wall, although it succeeds well as a bush; when studded with flowers of various shades of rose it may truly be described as perfectly lovely.—*H. DUNKIN, Castle Gardens, Warwick.*

(To be continued.)

THE TURNING TIDE.

SLOWLY, almost imperceptibly as the rippling waves recede on the sandy shore, are the days lengthening, and the cheerful February sunshine reminds us that winter is fast losing its sting, and on the horizon, as it were, we can see the gladsome dawn of spring. Everyone is invigorated by the first bright days of the year, and none more than gardeners, for to them it is more than a matter of sentiment. We think of seasons in the past when the earth has been wrapped in the grip of ice and snow right through the present month and the early part of the next. We remember how we chafed at the enforced idleness, as we knew that it meant a rush of work when the weather broke. The diary told the dates upon which early Peas and Beans had been sown on previous occasions, but they had to wait, as also had many another operation; and so that law of rotation so necessary to the harmonious working of a well-conducted garden was for the time being thrown out of order.

But why ruminate on the past, just as we are entering on a new era, and one, too, so full of promise? As I write the balmy sunshine floods the earth, warming and drying with its cheerful rays. Everything seems glad, and after the long dreary time we have passed through the first signs of reviving animation are doubly welcome. Though the winter has been characteristic on account of its mildness, it has not been altogether favourable from a gardener's point of view. So continued has been the downfall of rain that it has been almost impossible to proceed for any length of time with outdoor operations, and there yet remains much to be done in the way of planting and alterations. On the other hand, we must not complain, for springs were empty, and many others beside water companies thought apprehensively of the future. Such fears have now vanished, springs are full to overflowing, and the store of moisture is insured for some time to come.

The tide is turning, and though we are yet only on the threshold of the busy season, the bright days bring their duties. No opportunity should be missed when the ground is in working condition of proceeding with kitchen garden operations. Most gardeners will already have sown the early rows of Peas and Beans, and perhaps are thinking of the Onions. So closely are the past operations of the gardener linked with the present, and the present with the future, that any omission tells its own tale. It is now that the benefits of rough digging and ridging in the autumn and early winter are felt. To some such work appears to be considered of little importance, yet why this is so it is difficult to explain, for we need not the aid of science to tell us that the action of the weather not only sweetens and pulverises the soil but renders it in good condition for the reception of the seeds in the spring. The question of labour is sometimes advanced as an excuse, but that is only a lame one, for double the work is necessary now where the operation was neglected, without the benefits.

Turn to the flower garden, and the same signs of activity present themselves, while the aspects are still more cheerful. There are the clumps of Snowdrops, so pure and chaste, the first emblems of spring. Who can look on them without feeling cheered and invigorated? One day we see nothing but the green points peeping through the surface, then the diminutive flowers, the stalks of which lengthen daily, and the blooms increase in size till we have the full-blown Snowdrop. One of the most charming pictures I know at the present time is a large kitchen garden, intersected in the usual way by walks at right angles. Along the verges of these are rows of Snowdrops planted close to the edging tiles, without encroaching on space required for other crops. It would be difficult to imagine anything more pleasing than these unbroken lines of pure whiteness in the February sunshine, and in many gardens the ever popular bulb might be so planted to great advantage.

Crocuses, too, are opening, and the herbaceous border shows many signs of floral life. The other day I came across the bright blossoms of *Omphalodes verna*, and several of the *Hepaticas* are

now very charming. Lovers of hardy flowers are daily watching their favourites in anxious expectations. To such the early spring has a particular charm, and one is apt to envy the enthusiast who has the facilities for growing them in quantity. How interesting are these habits, and with what unfailing regularity they follow each other in rapid succession! But the singing of their praises shall be left to abler pens than mine. Just a word about the Daffodils, which are peeping through and growing stronger day by day. Last week's Journal told of 22 tons of spring flowers being despatched from the Scilly Islands one day recently. What an industry this has become! and how much the inhabitants of the genial isles owe to these accommodating spring flowers! In our colder climate we must be content to wait a little longer.

"Ah! this does one good," said a gardener the other day, as he stood in the early vinery watching the invigorating effect of the sunshine on the foliage. In no portion of the garden is the turn of the tide felt with greater benefit than in the early vineries and Peach houses. In the absence of sunshine the foliage of the Vines is weak and without substance. Growth is slow, and even with great care mildew makes itself seen. The first bright days, however, make a difference; improvement is apparent, and the leaves rapidly take that green and leathery appearance that all gardeners like to see. How helpful, too, it is to the setting of the blossoms in the early Peach house, and also to the first plants of forced Strawberries; indeed, where can we look without seeing beneficial effects from February sunshine? Yet pessimists shake their heads and say we are getting on too quickly, and shall have to suffer for it when March comes in. Let us, however, make the most of the present and hope for the future.—MONOCLE.

MADAME CARNOT.

MOST readers of Chrysanthemum notes in the Journal will remember that a collection of cut blooms was staged at the Ghent Show. These blooms were contributed by several members of the National Chrysanthemum Society, and included in the collection was a bloom of Madame Carnot sent from the gardens here, and which received a special mention from the Jury. I am very pleased to say that I have just received through Mr. T. Bevan a certificate from the Ghent Society for the bloom mentioned above. We staged nine blooms of Madame Carnot last November at two shows, and were awarded premier prize for the best bloom in the show in each case. Seven of the nine blooms figured in first-prize stands, and two in second-prize stands, and were exhibited at the Highgate and Finchley Chrysanthemum Exhibitions. We were also awarded the prize for the best bloom in the Highgate Exhibition with Madame Carnot in 1895.—H. A. PAGE, *The Gardens, White House, New Southgate.*

A TOUR ABROAD BY A HAPPY TRIO.

(Continued from page 99.)

THE journey to Paris was, like most of the travelling, done at night, and we consequently had little opportunity of seeing the country through which we passed. After leaving the Belgian frontier we could not fail to notice that we were traversing a busy industrial part of France, and one large town was conspicuous by the lurid glare thrown upon its buildings from numberless furnaces and lofty chimneys, suggesting very vividly that part of our native land known as the Black Country. The express steamed into the Gare du Nord at Paris shortly before midnight, and we beheld a friend waving his umbrella to attract our attention. We were quickly at the hotel, and there found Mons. Ernest Calvat, and learned we should have congenial company.

Despite the lateness of the hour, we strolled for a time up and down the Boulevard des Italiens and the Boulevard Poissonnière, which at midnight are as densely thronged with foot passengers and vehicular traffic as they are at midday, the numerous cafés and restaurants being all brilliantly lighted up, and the whole scene well worth a visit. Though early morn before we retired to rest we had to rise at half-past six so as to breakfast and be at the Palais de l'Industrie by eight, when the judging began. This operation was a somewhat arduous one, for the method of staging the exhibits varies considerably from that adopted in England, the exhibits in the same class being often in quite different parts of the building, and consequently necessitating much needless running about. The main features of the show have been given in a former issue of the Journal, but there are a few items of interest that may be usefully inserted here. The judging was performed by six sections of the Jury, the first three being for Chrysanthemums, the fourth for fruit, fruit trees, and ornamental shrubs, the fifth for foliage and flowering plants, bouquets, and subjects for the decoration of apartments, and the sixth for market garden produce.

At the hour appointed the members of the Jury were called into the

Secretary's office, and the roll was called. Each member was then supplied with a stiff covered book of tabulated forms and a lead pencil. The forms contained columns for the No. of the class, the No. of the exhibitor, the nature of the exhibit, the points allotted, the award made, and remarks. When the whole proceedings were over the Secretary of each section wrote out a formal report, which was signed, and then transmitted to the proper authority, presumably the Secretary of the Society, under whose auspices the Show was held.

The next part of the first day's performance was the luncheon offered to the Jury. This took place at the famous Restaurant Ledoyen, only a stone's throw from the Exhibition Hall. Mr. Viger, formerly Minister of Agriculture, and now President of the National Horticultural Society, took the chair, there being a large number of eminent French horticulturists present, besides the members of the Jury. After other toasts the Chairman gave the "Health of the Foreign Members of the Jury," in a speech that was warmly received, to which I replied in my best French. Handshaking, introductions to new friends, the renewing of old acquaintances occupied some time, and then we returned to the Palais de l'Industrie. But what a sight! When we left the building had not been opened to the general public; when we returned there was a concourse of visitors, all crowding in as hard as they could go, and waiting their turn with heroic patience.

Hearing that we should have no time to go to Grenoble, Mons. Calvat had specially come to Paris to meet us, with seven well-known members of the Chrysanthemum fraternity. We had a most sociable dinner with the great grower. Our host was in the best of spirits, for after a long series of triumphs elsewhere his success in Paris that day was only another tribute out of many to his skill as the foremost producer of new seedlings. He had carried off the special gold medal presented for competition by the Minister of Agriculture, to say nothing of half a dozen more, and had been awarded more first-class certificates for his novelties than almost all the other exhibitors of new seedlings put together.—C. HARMAN PAYNE.

(To be continued.)

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last the annual general meeting of the members of this Society was held at Anderton's Hotel, Fleet Street, Mr. R. Ballantine occupying the chair. After the minutes of the last annual general meeting had been read and confirmed, the Secretary submitted the report and financial statement for the past year, and also a statement as to the reserve, all of which were considered as being eminently satisfactory, and reflecting the greatest possible credit on the Executive. The following is the text of the report.

REPORT OF THE COMMITTEE, 1896.

In presenting their annual report and statement of accounts for 1896, your Committee can refer with pride and satisfaction to the remarkable success which attended the celebration of the Jubilee of the Society in November last. The programme of the Committee, liberally conceived, was carried out with spirit and with a measure of *éclat* beyond the most sanguine expectations of the Executive.

The widespread interest taken in the Jubilee was shown from the fact that the large sum of £382 6s. was raised as a special Jubilee Fund. The two exhibitions held during the four days set apart for the celebration were on an extensive and imposing scale; the extent of the competition and its keenness in some of the leading classes was almost unprecedented. Groups, specimen plants, and cut blooms of Chrysanthemums were shown of the highest quality, while the display of fruit and vegetables—the latter mainly in response to the valuable special prizes offered by several of the leading seed houses in the kingdom—was of so extensive a character as to establish a record in London exhibitions. Among the many attractive special prizes offered one was of a gratifying international character—a gold medal presented by the American Chrysanthemum Society. The banquet was a social observance indispensable to such an occasion, and was carried through by the President in a way which did himself, the Society, and its guests honour. The Conference, which was well attended, gave occasion to the reading of some excellent papers, which form admirable additions to the literature of the Chrysanthemum. The Directors of the Royal Aquarium increased their special donation to the Jubilee Fund from £75 to £100.

By way of enabling the many societies in affiliation to participate in the Jubilee celebration a bronze Jubilee medal was presented to every Society in affiliation on October 1st last, and it is gratifying to know there was displayed on the part of local exhibitors the keenest rivalry in becoming the possessors of these medals.

The Jubilee Sub-Committee have earned the thanks of the members for their labours in bringing the celebration to such a successful issue.

The Jubilee edition of the Catalogue brings the work of the classification of the Chrysanthemum up to last season, and it is a most useful companion to the Centenary edition. Your Committee have acknowledged the labours of the Catalogue Revision Committee by making them the recipients of the medals of the Society.

Finding some difference of opinion existing in reference to the classification of a number of incurved varieties of recent introduction which do not find a place in the Jubilee Catalogue, your Committee appointed an influential Special Committee of leading growers to deal with the doubtful varieties. This Committee have made a report which has been accepted, and it finds a place with the published annual report, schedule of prizes, &c.

Illustrative of the Society's widespread influence, it may be pointed out that the year 1896 was also a noteworthy one in its foreign relations. Besides the ordinary work of the department, it is gratifying to record that early in the year the first German Chrysanthemum Society (Hamburg) made application to be added to the list of affiliated societies.

The Jubilee festivities were no sooner over than the Society, following the example of 1889, appointed an official deputation, consisting of Messrs. T. Bevan, H. J. Jones, and C. Harman Payne, to visit certain Chrysanthemum shows on the Continent. At Ghent the Society for the first time in its existence figured as an exhibitor with the most satisfactory result. The reception everywhere accorded to this deputation was of the heartiest nature.

One of the results of this continental trip was that the French Government appointed Mr. Harman Payne a Chevalier of the Order of the Mérite Agricole, in recognition of his services in the cause of the Chrysanthemum.

The meetings of the Floral Committee during the past year brought together a large number of novelties, from which a judicious selection was made for certificates of merit. Each year's experience operates to

set the standard of comparative perfection higher, and the granting of certificates of merit is now made only after the fullest consideration.

As evidencing the growth of the Society since January 1st, 1896, thirteen Fellows and 175 ordinary members have been elected, and twenty-seven societies admitted to affiliation.

Your Committee have thought the occasion of the Jubilee celebration a fitting time to elect some individuals to the position of honorary Fellowship, and the following are nominated to that honour as having in various ways rendered conspicuous service to the Chrysanthemum:—Messrs. Henri de Villemorin, Paris; H. Martinet, Paris; O. de Meulenaere, Ghent; B. Wynne, Chairman of Committee; T. Bevan, Chairman of Floral Committee; H. J. Jones; C. Harman Payne, Foreign Corresponding Secretary.

Your Committee owe a deep debt of gratitude to their honoured President, Sir Edwin Saunders, for his continued interest in the Society, and for his generous support given to the Jubilee celebration. They desire most heartily to thank all donors to the Jubilee and special prize-funds, through whose contributions your Committee were largely enabled to make the Jubilee celebration such a splendid success.

February 18th, 1897.

Mr. B. Wynne moved the adoption of the report and accounts, and in so doing offered his congratulations on the result of the Jubilee celebration. He thought that such an exceptional record spoke well for the wisdom and judgment of the Committee. The Chairman, in putting the motion, said that this time last year he did not expect to be able to congratulate the Society on such a splendid outcome of their efforts, and the same was carried with acclamation.

Mr. Wynne, not seeking re-election as Chairman, was awarded a vote of thanks for his services in that capacity.

Compared with Vouchers and found correct,

February 18th, 1897. GEORGE J. INGRAM }
HERBERT J. CUTBUSH } Auditors.

The Chairman then commenced a series of interesting presentations, beginning with Mr. R. Dean as the senior officer. A gold Jubilee medal and an illuminated address with the thanks of the Society for the many duties performed by him were then presented to Mr. Dean, who suitably replied. A similar presentation was then made to Mr. C. Harman Payne as Foreign Corresponding Secretary. Silver-gilt Jubilee medals were then presented to Mr. Wynne, and one was awarded to Mr. T. W. Sanders, who through an accident was unavoidably prevented from attending. Bronze Jubilee medals were also presented to Mr. Ballantine, Mr. Bevan, and Mr. Williams, and the members of the Catalogue Committee also received similar recognition for their labours. A letter from the President, Sir Edwin Saunders, was read, offering his felicitations.

The election of officers was then proceeded with, with the following result:—President, Sir Edwin Saunders; Treasurer, Mr. J. R. Starling; Chairman of Committee, Mr. T. W. Sanders; Vice-Chairman, Mr. R. Waterer; General Secretary, Mr. R. Dean; Foreign Secretary, Mr. C. Harman Payne. One-third of the General Committee retiring by rotation, scrutineers were required to examine the balloting papers, Messrs. Crane, Needs, Berridge, and Taylor being appointed. A large number of nominations having been made, the following were announced by the Chairman as having been duly elected—viz.,

Mr. H. Cannell, Swanley, Kent, 63; Mr. W. Holmes, Dryburgh Road, Putney, 65; Mr. D. Ingamells, Covent Garden Market, 66; Mr. W. H. Lees, Trent Park Gardens, Barnet, 72; Mr. W. Mease, The

Gardens, Downside, Leatherhead, 77; Mr. J. W. Moorman, The Lodge, Victoria Park, N.E., 75; Mr. R. Reeve, Hadley Green, Barnet, 55; Mr. J. Williams, 15, Dynevor Road, Stoke Newington, 76; Mr. J. H. Witty, Nunhead Cemetery, S.E., 80; Mr. J. Lyne, 47; Mr. A. Newell, 35; Mr. Gleeson, 32; Mr. Howe, 29.

The election of new members then followed, and the following societies were admitted in affiliation:—The Swansea Working Men's Club and Institute Chrysanthemum Society and the Putney and Wandsworth Chrysanthemum Society.

A few other items of formal business nature were then disposed of, and the meeting, which was very largely attended and of a most hearty nature, concluded with a vote of thanks to the Chairman, upon the motion of Mr. Wilkinson, the Secretary of the Royal Aquarium Co.

NOTES ON PHALÆNOPSIS.

THE glorious racemes produced during the present and few succeeding months by some of the better known species of Moth Orchids are enough to tempt anyone to take up their culture, and he who fails to admire these must certainly have entirely lost his sense of the beautiful. Nothing in the whole range of Orchids could excel the graceful pose of the racemes, the richness and exquisite contour and delicate texture of the blossoms. It is remarkable, too, if a little thought is given to the matter that such a sumptuous display should be the outcome of such meagre fare, for not one of these Orchids cares for or will be satisfactory with anything in the way of manurial stimulants.

The roothold for these Orchids is an important matter, and whatever is used for them must be of a very lasting description. Wood is without a doubt the most natural holding for them, and the way the roots attach themselves to it and thrive upon it is ample evidence that it is suitable for them. So long as this remains sound nothing could in short be better; but even the most enduring kinds as a rule soon decay in the heat and moisture of the Orchid house. Then it will be found rather difficult to re-establish the plants upon new blocks, or in new baskets, cylinders, or whatever may be used. In the case of the latter the roots will often be found running the entire length of the rods, and therefore not easily detached, and when detached difficult to induce to take hold of a fresh piece.

When baskets are used the roots are usually much entwined about the rods, and here the difficulty is as great as with cylinders. A partial way out of these difficulties will be found in growing most of the stronger or more robust species in pots nearly filled with clean rough potsherds, with a surface layer of sphagnum moss. These may, of course, be suspended from the roof if required, but the chief advantages will be found in the fact that they very seldom need be disturbed at the roots, and when eventually this does become necessary the roots, by their freer ramification among the crocks, will not suffer so much, and the plants are in consequence easier re-established.

I do not mean by advising pots, that the ordinary make and no other should be used, for the light pans so often recommended answer exactly the same purpose, and are in fact superior to the ordinary kind for weak species and small plants. The layer of moss need only be thin, and may be added to as time goes on if necessary. Great care is necessary not to damage the roots in fixing, and the plants must be made quite firm, tying to upright stakes being required if the roots are not plentiful. If baskets or cylinders are used the same care as to fixing is necessary, but the roots in this case are not so liable to injury with ordinary care.

Watering at the root must be judiciously attended to all the year round. The drying of these plants during winter, which I have often warned growers against, is still practised to a certain extent, and is a relic of the barbarous treatment that used to be meted out to all Orchids alike, whether it was a pseudo-bulbous kind or one of the distichous-leaved race without those sustaining organs. Allowance must be made for the state of growth, also the state of the atmosphere and climatic conditions outside; but a starving régime, brought about by entirely withholding water, cannot be too strongly deprecated. Watering over the leaves is not as a rule advisable, occasional success obtained under the circumstances notwithstanding.

Temperature is an important factor. As the year advances the increased light and warmer outside conditions must be met with a slightly higher temperature. The maximum will be reached at midsummer, and continued until the days again begin to shorten,

when it must again recede, not all at once, but very gradually. Healthy plants with abundant leafage stand a fair amount of sunlight and air, especially towards the end of summer, when it has a tendency to consolidate the plants and render them less likely to suffer from slight alterations of temperature, sometimes unavoidable during winter. It may be taken as a guide that the minimum winter temperature must never be less than 60°, while 90° is quite high enough as a summer maximum by day, 70° by night.

It is impossible to go minutely into all the details of culture, but the cardinal points once mastered beginners will find little difficulty in growing the species named below. One thing must not be lost sight of—that is, that Phalænopses one and all are very free blooming plants, and sometimes push flower spikes when the plants are hardly capable through weakness, or owing to not being well established, of bringing them to perfection without risk of injury. In such cases remove some of the flowers, and whatever number is left do not let the plants carry them until they fade, but cut and place in water after about a week or ten days.

P. amabilis may be styled the most popular in the genus, and produces large racemes of white blossoms with a prettily spotted lip. It first flowered in England in 1838, and is a native of Java. *P. grandiflora* is a large flowering plant, but much resembling *amabilis*. It is a Bornean kind, introduced in 1847. *P. Ludemanniana*, *P. Schilleriana*, and *P. Stuartiana* (fig. 35) are all natives of the Philippine Islands. The first-named is slightly more tender than the other two, and bears white flowers prettily marked with brown and purple. *P. Schilleriana* would be worth growing for the sake of the beautiful foliage alone, and *P. Stuartiana* is not far

FIG. 35.—PHALÆNOPSIS STUARTIANA.

behind it in this respect. Both produce splendid branching spikes of flowers, the ground colour of these varying from creamy white to the deepest rose.—H. R. R.

SALE OF ORCHIDS AT MARKS TEY.

AT Messrs. Horsman's sale good prices were realised for the plants by Messrs. Protheroe & Morris. Nothing of great rarity was included, but fine plants of popular kinds sold well, especially *Odontoglossum crispum*, owing possibly to a report that it is becoming scarce in its habitat. *Dendrobium Wardianum album* brought 4 guineas and 3 guineas, while a good form of *Lælia purpurata* went for 3½ guineas. Some unflowered seedlings of *Cattleya* were knocked down for 10 guineas, a good price considering that the parentage was not forthcoming.

FRENCH WINE.—The annual report of the Commissioners of Indirect Taxes, a full digest of which has recently been published in the "Moniteur Vinicole," confirms the estimate formed at the close of the vintage as to the quantity of wine made in France last year, the total yield of the 4,321,080 acres under cultivation in 1896 being 1,004,763,420 gallons. This is equivalent to an average yield of 234 gallons per acre, or 99 gallons per acre more than in 1895, and not far short of the almost unprecedented average obtained in 1893. But although there was an increase of the area under vintage cultivation in thirty-four departments, so many Vines were uprooted elsewhere that the total for the whole of France showed a decrease of 46,420 acres; and it is worthy of note that the acreage has been steadily decreasing for the last ten years, having been just 5,000,000 acres in 1886, though the yield of wine has, on the whole, been larger since.

WEATHER IN LONDON.—Brilliant sunshine has been sandwiched between soaking rains during the past seven days in London. On Thursday the weather was more like May than February, as were Sunday and Tuesday, while the intervening days were dull, cold, and wet at intervals. Evidences of spring are seen on every hand. Wednesday opened dull and colder.

— WEATHER IN THE NORTH.—The past week has been, on the whole, pleasant, although there has been but little sunshine, and the westerly winds have been occasionally high and cold. Drizzly rain has been frequent; the afternoon and evening of Saturday were unpleasantly wet. Monday was quite spring-like, with gleams of sunshine; Tuesday morning dull and colder.—B. D., *S. Perthshire*.

— GARDEN PATHS.—Where gravel or other suitable material is scarce I can recommend coke breeze, as it is called, for garden paths as an excellent substitute. It is less subject to harbour weeds, forms a firmer and drier walk than coal ashes, and what is of no less importance, it resists the action of sharp frosts—that is, in not becoming loose on the surface, and when thawing not soft and sticky. Being also of a uniform “sifting,” the coke breeze forms a neater surfacing than either coal ashes or the breeze or cinders obtained from foundry furnaces.—W. G.

— THE HYGIENE OF GRAPES.—Recent testimony as to the hygiene of fruits places Grapes high in the list. For certain diseases (says the “Grape Belt”) they are a specific, and the “Grape cures” of France and other countries have a deservedly high reputation. Grape sugar is more easily digestible than cane sugar. The fruit acids are beneficial in rheumatism, and as a preventive of certain injurious deposits in the system, especially of old people. The Americans, the largest consumers in the world per capita of sugar, ought naturally to be large consumers of fruit. Ripe, fresh fruit, or some form of cured, canned, or preserved fruit should, both by the logic of economy and health, form a regular portion of every meal of every American family.

— ROOTING CARNATION CUTTINGS.—When your correspondent “Bassil” asserts that I am “behind the times” his note, unfortunately for him, does not display much advancement on the road of progress. If he looks back he will find more than 90 per cent. rooted. My last box has yielded 97 per cent. Carnation cuttings do not appear to root satisfactorily in a warm house without the aid of bottom heat. We have had successes and failures. Our bottom heat pipes are 5 feet deep, and therefore practically no use. We might tell “Bassil” we found them there, having nothing to do with putting them in that position. We wrote for the good of those similarly situated to ourselves—and there are many. If we have helped them our object has been gained, whether the writer or method is “behind the times” or not. It is a pity “Bassil” hides so much valuable information. When room is limited, as it is in most gardens, and varieties for propagating as well, we see no need for 3-inch pots for four cuttings when thumbs would do equally as well—a saving of room, which in these days is certainly a progressive step.—W. BARDNEY.

— BIRMINGHAM GARDENERS’ ASSOCIATION.—“Herbaceous Plants” was the title of a dissertation given by Mr. Edward J. Baillie, Chester, to a large gathering of the members of this Society on the 15th inst; Mr. W. B. Latham in the chair. Mr. Baillie dealt with the subject in a very entertaining and graphic manner, without, however, much reference to particulars in the cultivation of the plants, but more in regard to their general position, from a decorative point of view, their classification, and their rapidly growing popularity. The essayist’s references to the folk-lore, poetry, romance, and mythology attached to flowers were most instructive, and comparisons were also made between arrangements of cut flowers. A study of botany was pertinently advocated as part of the gardener’s education, added to which was a knowledge of the etymology of plant nomenclature, though a profound knowledge of Greek and Latin languages was not necessary towards the attainment of a useful and interesting acquisition of those sciences. An interesting discussion, joined in by several of the members, on the various details embodied in Mr. Baillie’s composition of matter, concluded the proceedings.

— TWO EARLY WASPS.—I noticed the paragraph on page 136, and may say I have killed two large wasps indoors, one on December 18th and the other on February 7th last.—M. B., *Co. Meath*.

— A PROLIFIC HYACINTH.—Mr. Bardney writes:—“Since I wrote you about a prolific Hyacinth the ‘missus’ has been growing, I have discovered that it has produced another spike, making seven instead of six, as previously stated.”

— POLYANTHUS NARCISSUS MONT CENIS.—A correspondent says:—“Polyanthus Narcissus Mont Cenis is a good early variety, in fact one of the best, and should be grown by all where this class of flowering bulbs are appreciated. It is as early as States General, and gives a greater profusion of flowers than that variety.”

— SNOWDROPS.—A typographical error in the Journal of February 18th (page 133) may perhaps be misleading to some. In “Hardy Flower Notes” I am made to say, “The Common Snowdrop, looks small and slender beside Elwes’, one of the best forms of Imperati’s great Italian one.” This should read, “Elwes’ one, or the best forms, &c.” I observed it on receiving the Journal, and was about to write when one of my most valued correspondents sent me a letter to call my notice to the error.—S. ARNOTT.

— WINDOW PLANTS.—At this season house plants in bloom are grateful for an occasional feeding with liquid fertiliser, which gives the leaves a deeper green, and increases the number and size of the flowers. Any perfect commercial plant food can be used in solution, but cow manure is quite as satisfactory, especially if a little ashes can be mixed with it for extra potash, and the ingredients steeped in a barrel of water for several days. This liquid should then be diluted until it has the colour of weak tea, for if applied too strong or too freely it is sure to injure the plants. At first, says a writer in an American contemporary, the solution should not be given oftener than once a fortnight, but it can be gradually increased in frequency until it is used as often as once a week or once in five days.

— HORTICULTURE IN KANSAS.—An American contemporary says this is decidedly slipping behind in its commercial aspects, according to the figures published in the tenth biennial report of the State Board of Agriculture (1895-96), a copy of which has just been received. In 1895 the cash values of garden and of horticultural products are respectively given as 939,000 dols. and 930,000 dols., whereas in 1896 the figures show only 760,700 dols. and 642,300 dols. respectively. This decrease in value may perhaps be accounted for to some slight extent by decreasing value of the soil products, but the report shows that the areas under cultivation are largely diminished as regards all crops excepting Strawberries, which show an increase of one-twelfth. In importance as regards number of trees, Apples rank first, with over seven millions, and Peaches are second, with about one-half that number. Pears are but little grown.

— ROYAL METEOROLOGICAL SOCIETY.—At a meeting of this Society on Wednesday evening the 17th instant, Mr. Edward Mawley, F.R.H.S., President, read a report upon the phenological observations during the past year. He showed that throughout the flowering season wild plants came into bloom much in advance of their usual time, and were, as a rule, earlier than in any recent year since 1893. The wealth of blossom on nearly all kinds of trees and shrubs was a noteworthy feature of the spring and early summer, while the abundance of wild fruits in the autumn was even more exceptional. From an agricultural and horticultural point of view the one great drawback of the year, which must have otherwise proved one of the most bountiful on record, was a drought that lasted almost without break—at all events as far as vegetation is concerned—from March to September. The Wheat crop proved the largest and best for many years, while there was a good yield of Barley and Potatoes. The small fruits were also good. With these exceptions all the farm and garden crops were more or less indifferent, the crop of hay being especially scanty. The Hon. Rollo Russell gave the results of some observations on haze and transparency which he had made at Haslemere, in Surrey. From these it appears that the clearest hours at a good distance from towns are from about noon at 3 P.M. The clearest winds are those from S. to N.W. inclusive, and especially W.S.W., W., and W.N.W.; the haziest are those between N. and E. On bright mornings with a gentle breeze or calm, from autumn to spring, the haze or fog which has lain on the low ground frequently covers the hills in the course of its ascent a few hours after sunrise. At any distance within 100 miles of London, or of the Black Country, observations requiring clear views are likely to be interfered with when the wind blows from their direction, and should therefore be taken early.

— **STOCK FOR TREE PÆONIES.**—Mr. Bardney would like to know if any correspondent can inform him on what stock Tree Pæonies are worked, and at what period of the year? They are certainly worthy of more extended cultivation, but they are of slow growth, and somewhat costly for a start.

— **LEMONS FROM CUTTINGS.**—Mr. J. Vearey writes from The Gardens, Gogerddon Hall, near Aberystwith:—"It may be interesting to some of the readers of the *Journal of Horticulture* to know that Lemons can be grown successfully from cuttings. We have some large trees growing on the back wall of a lateinery that I raised from cuttings about twenty years ago, which bear large crops of very fine fruit annually—in fact, they are setting and ripening their fruit all the year round, and we are never without ripe fruit on the trees. Is it generally known that the Lemon will bear so freely from cuttings?"

— **ILEX CRENATA.**—When making a choice of dwarf evergreen shrubs this Japanese Holly should not be overlooked. It forms a compact growing bush usually from 3 to 4 feet in height by the same in width, though it often attains to larger dimensions. The leaves are usually ovate in shape with crenate margins; in the variety known as *I. crenata* major, however, the leaves are almost round. The leaves of the type are green, but there is a variety known as *I. c. variegata* which has its leaves prettily blotched with yellow. The type, together with its several varieties, are easily grown and readily propagated. Cuttings should be taken in the autumn and put in sandy soil in a close frame, when they will root during winter. A very good way to grow this shrub is to plant it rather thinly in a mass in the shrubbery or bed on the lawn, and fill the open spaces up with Lilies.—W. D.

— **EVAPORATION FROM TREES.**—Dr. Rothrock calls attention in "Forest Leaves" to the observation of Dr. Evermayer for the Bavarian Government, who declares that the evaporation of moisture from a forest area, including transpiration from the leaves, exceeds by 50 per cent. the evaporation from a water surface in the open, and if, therefore, we cut off great areas of forest it is not improbable that the surrounding atmosphere is much less humid, and for this reason the ground will dry much more rapidly. This will account to a certain extent for the killing quality of the droughts in some recent years. A diminished rainfall alone will hardly account for their severity, but if we couple with this the fact that evaporation from the ground is more rapid, we have some additional reasons for the extreme dryness which has prevailed.

— **INDIAN FOOD GRAINS.**—In the course of a lecture on "Some Food Grains of India" Professor A. H. Church observed that the Indian famine was due to a lack of self-help on the part of the natives rather than any lack of food. India is a great food-producing country, and as such had helped to lower the prices of food in the United Kingdom. The lecturer said that a large number of different vegetable substances might be used as articles of food. He had studied no fewer than seventy varieties of air-dried grains and seeds, and there were no doubt many more that might have been used. Most Indian Grasses were much charged with adventitious mineral matter. By due commixture of food stuffs belonging to different classes, such as cereals and pulses, a sufficiently near approach to a nutrient ratio could be secured. Another condition required was a suitable proportion of oil or fat.

— **THE COMMONS PRESERVATION SOCIETY.**—This Society has prepared a scheme for the regulation of Ham Common and lammas lands, and this is being considered by the Board of Agriculture. The joint Committee appointed by the Open Spaces Societies to endeavour to secure the dedication of an open space, playground, or place of historic interest or natural beauty, if possible, in each parish in the United Kingdom as a permanent memorial of the Queen's reign has circulated a memorandum on the subject to all district and parish councils, and other local authorities in the country. The provisions of the Hastings Harbour District Railway Bill, now before Parliament, are being closely considered; for should the proposed undertaking be carried into effect, not only will a part of the foreshore be enclosed and Ecclesbourne Glen spoiled by an embankment, but East Hill, an open space which cost about £25,000 to acquire, will be disfigured. In addition to this the scheme would destroy the beauty of the prettiest part of Alexandra Park by the construction of a viaduct. The Society will secure the opposition of the Bill in Parliament. The practicability of preparing legislation for the better protection of commons, heaths, and woods from malicious and wilful injury by incendiaries is under consideration, and it is felt that these evils would be greatly remedied if magistrates were enabled at petty sessions to deal with these offences.

— **THE ROSELLE.**—The Roselle, *Hibiscus Sabdariffa*, is a native of tropical Asia, resembling the Okra in growth, possessing great resistance to drought and yielding an acceptable food product. It has been tried in agricultural stations of southern California, where it is said to be ornamental, with dark red stems and pods showing through rather scanty green foliage. The juice from the fleshy calyces makes a cooling acidulous drink, and is useful for jelly. The mucilaginous properties of the juice render the setting of the jelly certain, and its dark cherry colour and sprightly acid make it very desirable. As it will grow in hot, arid situations, Mr. Wickson, of the Experiment Station at Berkeley, is distributing seed to those parts of the State where it will thrive.—("Garden and Forest.")

— **CHAMPAGNE FROM DRIED PEARS.**—A fact which may have a somewhat important effect upon the future of the Pear market, says "The Grocery World," has just come to light. It is that a rapidly growing demand has been established in Europe for dried California Pears, which are used for the manufacture of champagne. This fruit, when used for wine, is said to yield a much greater revenue than when sold simply as dried fruit. Not only is there a demand in Europe for California dried Pears to make champagne from, but their use in their natural shape is also greatly increasing. The fruit is being sent direct from California, which reduces the freight charges, there being no across-country tolls to meet.

— **PINE APPLES AND DIPHTHERIA.**—Regarding a severe case of diphtheria, a Southern writer recently said that a ripe Pine Apple was procured and the juice expressed, and given to the patient in teaspoonful doses slowly. The authority for the statement adds: It seemed to clear the throat, swallowing was easier, and in a few hours the child was sleeping. Recovery followed. Pine Apple was subsequently used in a number of other cases with every success, and the people of the neighbourhood think it better than any medicine that comes from the drug store. Diphtheria is too critical an illness to warrant experimentation. A physician should be summoned always, but if the doctor endorse such a treatment then afflicted childhood should be indeed happy. Those of adult age will regret that the discovery was not made earlier in the world's history.—("California Fruit Grower.")

— **WOLVERHAMPTON HORTICULTURAL CLUB.**—The monthly meeting of this Club was held at the Midland Café on the 2nd inst., Mr. J. F. Simpson in the chair, when a most instructive and interesting paper on Orchids was read by Mr. G. Burrows, head gardener at Berwick House, Shrewsbury. The essayist first gave an outline of the different countries in which the most important genera are found, also stating the altitude and conditions under which they grow in their native homes. He then entered more fully into the details of their cultivation in houses, indicating the style of houses most suited to the different classes of Orchids. By the able way in which he handled the subject the lecturer proved himself to be an expert in the knowledge of this beautiful class of plants. Discussion followed, in which Mr. G. A. Bishop, Mr. Bradley (Vice-Chairman), and others took part, and a hearty vote of thanks to the lecturer closed a very successful meeting.

ENDIVE.

WE have long since discontinued the culture of any other variety than the Improved Broad-leaved Batavian. When this kind is well grown and thoroughly developed we find it much better and more appreciated than small later sown plants. Our practice is to fill all the spare lights we can and then pack good batches close to the walls on the south side of Peach houses and vineries. Close to the walls of such houses a very severe frost is necessary before covering is really needed. As a rule the plants are safe against 14° or 15° of frost, and a few Spruce branches or Yew prove ample to protect them through ordinary winters.

We have for many years ceased attempting to blanch Endive outside by the many methods recommended. If we have no room in the Mushroom house we place the plants closely together in a deep box with soil about their roots, and then cover the box with slates. Early in the autumn this is our method, and we are inclined to think when the boxes are placed in brisk heat and the centres forced up quickly and well blanched it is not so bitter as when allowed to blanch under cooler and slower conditions.

During late autumn and winter the small varieties of Cabbage Lettuce are preferable to Cos. The latter are very bitter after the days and nights begin to be cold. In fact, when they can be cut outside late in the season they are very little superior to Endive, for they are bitter and somewhat tough. Although we keep what Lettuce we can, and store plenty of Endive as well as force Chicory, we are of opinion that good supplies of Mustard and Cress are more appreciated. In addition we also grow a good supply of Watercress in cold frames. We go to very little trouble, and the yield is both abundant and good. How we do this may be described before long.—PRACTICE.

VEGETABLE TRIALS IN SURREY.

WHILST it is possible for those who reside in the respective localities to take practical interest in any of the trials of garden products which may be conducted in their neighbourhoods in the county, yet the publication yearly of reports of those trials in small pamphlet form by the Technical Education Committee enables the results to be widely read, and thus be productive of great good. Very much interest is by such agency aroused in the county in reference to kinds and varieties of vegetables not well known, and as in all cases the name of the firm from whom originally obtained is given, the public are enabled to obtain samples if they so desire.

A few plots hitherto used in the county, especially those remote from headquarters, have been given up, as their situation rendered ordinary supervision difficult. Those retained for cropping this year are at Richmond, a light porous soil, and early; Egham, a deep sand; Bookham, loam on chalk; and Surbiton, a new plot, which is of very sandy loam on ragstone, varying in depth. All these plots are locally placed at the disposal of the Technical Education Committee free of cost. Owing to the increase of continuation school or boys' gardens in the county, for these run into several hundreds, it is found needful to, so far as is possible, supply them with good seed Potatoes and Peas of superior varieties to those usually obtainable through the local seedsmen.

For this purpose large quantities of seed Peas, in all cases fine and wonderfully clean samples, were saved from last year's trials, and most of these will be sent out in small quantities to the school gardens. Other portions of the best varieties, all of moderate height, will be grown expressly to produce seed at Bookham, where also on an equal portion of the large plot there will be grown some twelve or so varieties of the best early and second early Potatoes to give tubers for the same object. At Egham, one half the plot will be devoted to eight varieties of Potatoes, three rows of each being planted, to once more test the relative productiveness of small, medium, and large tuber sets, an equal number being planted in each row. The other half of this sandy plot will be utilised for a trial of Carrots and Beet, as these sorts invariably do well on the ground.

At Richmond one half the plot will be cropped with various early varieties of Potatoes, also to produce tubers for the boys' gardens, and the other half will be sown with small quantities of some twenty varieties of Boston grown Peas, kindly presented for trial by Messrs. W. W. Johnson & Sons. These are all of dwarf sturdy nature, and will be treated as in field culture. The Surbiton plot, which is situated in a very prominent position just within the entrance to the very fine group of allotments which the District Council has there provided, will be devoted entirely to variety trials.

The ground has been prepared for cropping by a heavy dressing of good manure, which has been well buried down in the process of trenching, work that has been well done. The ground had been previously poorly done, and only shallow dug. It is hoped as one result of the good dressing, and especially of deep working, that an object lesson of great value to the various allotment holders may later be furnished. As the plot borders the principal road through the allotments a narrow border will be sown with various flower seeds, amongst which will be both home-grown and German-grown Asters for trial.

The vegetable crops will comprise twenty-eight varieties of Potatoes, one row of each, planted at 30 inches apart; twenty rows of Peas, including all the finest of the varieties that were grown last year, and a few new ones; and about twelve rows of Onions, in six varieties, such as Ailsa Craig, Crimson Globe, Cranston's Excelsior, Inwood Favourite, Maincrop, and the Wroxton, all superior ones, the seed having been grown specially last year from some remarkably fine selected bulbs. This arrangement of the respective crops will admit of an entire change of ground next year. The Surbiton ground, being within easy reach, can have constant attention. Every variety will be well and legibly labelled, also with name of firm from whom originally obtained. The County Council does not in any way interfere between allotment holders and the seed trade, but is desirous of giving wider information respecting the best varieties, and very largely is in that respect successful.—A. DEAN.

RIVAL QUEENS.

IT must not be inferred from the above heading that an attempt is to be made to place the Queen of Flowers and the Queen of Autumn in the position of rivals—that they can never be. The one is the flower of summer, while the other enriches our greenhouses in autumn. There can be no rivalry between these two—each sways the world of horticulture in its own season and in its own sphere. But if we may have Queens in the floral world of summer and autumn, we are equally within our rights in instituting Queens of winter and spring, and in so doing we have two flowers to claim honour—the Chinese Primula and the Cyclamen. Which shall have the supremacy? Neither. Each in its style is almost perfect, and votes for the one would be about equal in number to those for the other. So must they remain as hitherto, rival Queens of surpassing beauty and exceptional utility.

With the advent of Christmas the reign of these flowers commences, and is continued well into the months of spring. In every garden, be it large or small, in every florist's shop that is worthy the name, and in every nursery in the country may these plants be seen. Not everywhere in a similar condition, however. Here one may see Cyclamens in perfection, and there Primulas, while in another place

neither will be worthy of more than a passing glance, and even this may show nothing better than poor, unsubstantial flowers, and weak attenuated foliage. Go next to a home of both—he that home a nursery or a private garden—and what will be seen? Flowers clear in colour, symmetrical in contour, and perfect in substance; leaves rich in their various tones of green, developed fully as they should be, and of such texture as denotes inherent strength of constitution, natural to the stock and emphasised by the cultivation. Where may Cyclamens and Primulas be seen in this condition? may be asked. A reply to this can be given in two simple words—Sutton's, Reading, where the rivalry of the Queens is of the strongest, and where the most jealous partisan of either cannot say which must reign supreme, so peerlessly beautiful are both. The whites, the pinks, the roses, the crimson flakes, the bright reds, the crimsons, the blues, and the heliotropes of the Primulas; the whites, the roses, the purples, and the blackish crimsons of the Cyclamens are all to be seen at the Portland Road nurseries of the great Reading seed firm in perfection.

Many times before have tributes been paid to this firm for its services to floriculture in improving these two flowers, but once more it must in justice be given. This year, like its many predecessors, has brought strides, not big ones perhaps, but still perceptible, and taken on the firmest ground. Each season one may see this advancement, and each season sees more experiments being made, some of which are chronicled as successes, while others sink into oblivion as failures. No matter how many of the latter there may be, the work is still persisted in by Messrs. Sutton & Sons with the aid of their capable nursery foreman Mr. J. Martin, who is a true florist and hybridist. Thanks are due to all concerned in the work, and they are herewith heartily accorded.

On the occasion of a recent visit to Reading the writer, as a gardener, felt irresistibly drawn towards the Sutton Nurseries. Visions of loveliness seen there in past years floated through his mind, and the conclusion was arrived at that an hour or two there spent could not be other than profitable. So excellent were the many plants seen, that it will perhaps interest those readers who are so far unfortunate as to be unable to make a personal inspection if a brief reference is made in the pages of the *Journal of Horticulture* to those which appeared to stand quite at the top of the tree of beauty, and a commencement may be made with the

PRIMULAS.

Of these there are plain-leaved, Fern-leaved, and Moss-curved in the ordinary section, and the two former in the rightly named giant section. These giants make a strain that is really superb. The plants are floriferous without being coarse and ungainly, while they produce immense flowers from plants in comparatively small pots. As a matter of fact all are grown in 48's, a size that is handy for all purposes. Many of the individual flowers have the extraordinary diameter of 2½ inches, the trusses at the same time being of considerable size. Undoubtedly culture must have some effect on their uniform excellence, but that alone cannot do everything, for unless the quality is there no amount of cultivation can bring it forth. There are white, plain and Fern-leaved, pink and crimson giants, each of which is of equal merit, though many would probably put the white in the van. The blooms are symmetrical, of perfect form, and the leafage is abundant without detracting from the beauty of the flowers.

Turning now to the older section the same plethora of beauty and quality is apparent. Many readers can remember the day when Ruby King was shown and honoured at South Kensington, and they will recollect how much admiration was elicited by the variety by reason of the beauty of it, and the distinct advance it showed upon existing forms. Writing of the Reading Primulas in the *Journal of Horticulture* for January 9th, 1879, that prince amongst florists, "D., Deal," says regarding Ruby King, "I do not hesitate to say, taking all its points, is the most beautiful Primula that has yet been raised." Compare Ruby King of then with Brilliant Ruby of to-day, and the march onwards may be measured at a glance. Good as was the first named variety, Brilliant Ruby is infinitely superior. With such a name there is no need for description, and this is a condition common to all the Sutton varieties, for the firm has striven to give names which by their simplicity convey an exact idea of the merits and the colour of the variety. That now well known white variety, Sutton's Pearl, still occupies a foremost position by reason of its many merits. It is, in short, a Pearl of great beauty. Of Royal White one could not speak too highly, for of the ordinary Primulas it is the leader, and is usually recognised as such by those who are fully qualified to judge.

There are besides these the Reading varieties as represented by Reading Scarlet, Blue and Pink, which are of splendid quality, such as would have taken the whole of the floricultural world by storm ten or fifteen years ago. Gypsy Queen and Snowdrift remain as prime favourites yet, and are likely to do so for many years to come if the present standard of excellence is maintained by their raisers, as one would naturally expect it to be. The Fern-leaved Rosy Queen, with its handsome foliage and delicately coloured flowers, is peculiarly lovely, as is the chaste variety named Purity. Not many years ago the Blue Primula was usually held up to derision by reason of the washy colour of its flowers, but now criticism is much milder, for the blue is undoubtedly there, and everyone not colour blind must readily be able to see it.

Let us now look for a moment at a Primula that is entirely distinct from all those that have been mentioned in the foregoing paragraph, and which is none the less of the first merit. It is the Star Primula. In this we find a branching habit, an elegant style of producing its

flowers, and an extreme floriferousness that is not found among the Chinese single varieties. True, the individual flowers are smaller, but this is recompensed for by their numbers. Not that the Chinese must be omitted to make room for these; on the contrary, both should be grown, for each is useful and beautiful in its own particular style. The plants attain to a height of from 18 inches to 27 inches, and the fact that the flowers remain long in beauty when cut and placed in water will be another recommendation in the eyes of most people. The flowers vary in colour from pure white to pale purple, but more shades will doubtless be added before many years have gone by.

Double Primulas are perhaps even more beautiful than the singles; the colours are so clear, so chaste, and so delicate, the flowers so

so handsomely marbled as to render them worthy of being grown for this alone. To these recommendations must be added the one of fragrance, for this distinctly increasing in many of the varieties. We give in fig. 36 a photographic reproduction of one of Messrs. Sutton & Sons' plants that was in a 48-pot. This shows the blooms reduced, but unfortunately it was impossible to convey a proper idea of the beauty of the foliage on account of the photo being too black. Neither does the picture show the extraordinary number of buds with which the corm was bristling, though it depicts the purity of the colour and the great substance of the large-sized flowers.

Between the persicum and the grandiflorum sections it is difficult to choose. In the former one secures numbers of flowers and particularly

FIG. 36.—A SUTTON CYCLAMEN.

shapely, so useful, and so freely produced, and the plants of such useful size and form. For the adornment of rooms double Primulas in 48-pots are admirably adapted, and that this is recognised is proved by their growing use for this purpose. The colours represented are scarlet, Carnation-flaked (an appropriate name), white, pink, imperial purple, crimson, and blue, every one of which is of the best quality, and seen as they are at Reading in bold masses of distinct colour, produce a telling and at the same time very striking effect. It is but a cursory reference that we have been able to make to this unique collection, but it must suffice now. If any wish to see the plants it behoves them to go as soon as possible, for the zenith of their beauty is already getting past.

CYCLAMENS.

Truly are these flowers rivals of the Primulas. In addition to flowers of exceptional beauty the plants when well grown produce foliage

handsome leaves, while in the latter the blooms, though considerably larger, are not so abundant, and the leaves not, as a rule, so handsomely marked. The colours of the giants comprise white, cherry red, rose, pink, crimson and white, purple, and crimson, each pure and good. Of the persicums the best are certainly Salmon Queen and Vulcan, both of which are superb, the other colours being little, if anything, inferior. That their culture is thoroughly understood at Reading is emphatically demonstrated in the wonderful robustness of each of the plants, a condition of affairs that is by no means common in many parts of the country.

Besides these there are other plants at Reading that are well worthy of attention, such for example as the magnificent Cinerarias; but now all must be passed by, reserving them for a future visit to the town, which was erstwhile celebrated for its biscuits, but is now renowned for its Primulas and Cyclamens.—METROPOLITAN.

HALF-HARDY ANNUALS.

I WANT to put in a plea for these (although the past two or three seasons have been rather rough on them), because I think in the present system of gardening they are invaluable. When bedding out was the rage there was no place for them. "Geraniums," Calceolarias, Lobelias, and Ageratums occupied every available space, and it was only in the kitchen garden that a place could be found for even such things as Sweet Peas and Mignonette; but now since the public have come to a better mind, and our borders are filled with herbaceous plants and bulbs, there is not only room for them, but they are absolutely necessary, and things which were formerly only tolerated are now treated with some degree of respect, and due honour given to them. I say they are necessary for this reason, that when the early spring flowering bulbs which have been interspersed through the borders are passed there is much vacant space round the herbaceous plants which are coming on, and we want something to occupy these spaces.

Of late years the dwarf Gladioli-flowering Cannas have come very much into evidence and are to be found in most gardens, their foliage and flowers being equally effective. Still, one must only use them in moderation, and leave space for the half-hardy annuals for which I plead. It may seem absurd to mention amongst these such old and common things as Mignonette and Sweet Pea, but I have been to garden after garden and neither of these sweetly perfumed flowers was to be seen. Indeed, one of the strongest reasons for the exclusion of the bedding-out system was that there was no perfume whatever in the garden, for none of the flowers that I have mentioned had any perceptible odour, while the carpet garden with its pickled Cabbages, Alternantheras, and Houseleeks had not a vestige of sweet scent, and I have found when neighbours came in to see me a bunch of Mignonette was a great treat to them; and beside this there is another great advantage in half-hardy annuals—they are delightful for cutting. The lightness and elegance of form of many of them, and their brilliant and chaste colouring, is the delight of all those who arrange flowers and have to do so at a moderate expense.

Considerable improvement may be made, I think, in the manner of growing these. They are apt to be overcrowded, and if more attention were paid to thinning out much more satisfactory results would be attained; but it is very hard to persuade people that three or four plants well grown would be more effective than a couple of dozen crowded together. There is another point on which I feel more strongly every year—the superiority of single flowers over double ones. There was a time when I was very much attracted by the splendid Asters which Traffaut, Betteridge, and other growers have managed to raise; but even these are not very available as cut flowers for decoration, and therefore in my limited space I rely less on them every year. There is one double flower beside the Rose which I could not very well dispense with—the double Zinnia. Not only has it such very brilliant colours, but it has the advantage of supporting itself without any need of stakes; but the same objection applies to it as to the other double flowers—it is too stiff for tasteful decoration.

SWEET PEAS.—As I have already said, this in our bedding-out days used to be banished from our gardens, but now we see them on every side. Thanks to Mr. Eckford, we have the most varied hues now amongst them, from pure white to deepest crimson, including also sky blue, dark blue, rich purple, blue and purple striped, pink, carmine and white, brilliant scarlet, delicate rose, primrose yellow, and scarlet striped; nor has this great variety of colour been gained, as in the case of some flowers, at the expense of their delicious perfume, which has so well earned for them the name of Sweet. So that one is not surprised to learn that in America, where the love of garden flowers is so much associated with those that are suitable for house decoration, hundreds of acres of them are cultivated. They may either be sown in pots or in the open ground. They should be carefully thinned out so as to leave plenty of room for growing, and if the seed pods are picked off as soon as formed the blossoming time will be greatly prolonged. I do not think very much of that curious little dwarf which has come to us from America, Cupid, as it does not seem to flower very freely, and many persons express their disappointment at it. It is curious, and that is all one can say for it.

ZINNIA HAAGEANA.—One can hardly praise too early the bright orange coloured Zinnia. It grows about a foot high, and comes in admirably to fill up the spaces made when some of our dwarf growing spring bulbs have died down, and its brightness makes it most desirable for cutting.

COSMEA BIPINNATA.—I had heard much of this annual, and tried it for the first time last year, and I am afraid the season was an unfavourable one for it, as I was disappointed with it. The plants grew well and the foliage is effective; the flowers, too, are handsome and varied in colour. They are borne on stout footstalks, and remind one somewhat of single Dahlias; their colour is white and heliotrope, though I find it described in some catalogues as rose and white. It is somewhat late flowering, and the heavy drenching rains of September caused the plants to grow so much into leaf that the flowers were somewhat sparingly produced. I am told that this is not its character, and that in a more genial season it flowers very freely, and I shall hope to try it again; the foliage is especially handsome. It is a native of Mexico, and sometimes called *Cosmos bipinnatus*.

NICOTIANA AFFINIS.—This is a delightfully sweet-scented flower, vigorous in habit and very floriferous; the flowers are white, and open towards evening and continue in flower all night, and those who like when they go out into their gardens in the evening to be surrounded by

sweet perfumes ought not to neglect this plant. It is one also that is admirably adapted for pot culture.

SALPIGLOSSIS.—It is hardly possible to speak too highly of the beauty of this half-hardy annual with its gorgeous and unique colouring. Many of the flowers have quite the appearance of enamel, and hardly any of them are self-coloured, but are veined. Thus orange, salmon, cerise, violet, and other striking tints are seen in unusual combinations, and the effect is very grand. They cannot be said to be very sweet scented.

LEPTOSYNE MARITIMA.—This is sometimes known as *Coreopsis maritima*, and is a showy Californian annual, half-hardy in this country; the flowers are of a bright yellow colour, somewhat like a yellow Marguerite, and as they are borne on long stout footstalks they are valuable for cutting; as a plant it is also showy in the garden.

NEMESIA STRUMOSA SUTTONI.—This is a very beautiful half-hardy annual, very variable in colour, including shades of yellow, bright orange, crimson, rose, and white; it is very free flowering, and continues in bloom for a very long time. Like most flowers of this class, it succeeds best when sown early in the year, then pricked out into boxes, from thence into the border. It is frequently used for beds, and from its long continuous flowering is valuable for such purposes.

MARGUERITE CARNATIONS.—A very charming and sweet-scented annual. It is not only valuable for the borders, but also for pot culture, flowering freely during the autumn and winter months. The flowers have the old clove perfume, and a pleasant odour is diffused through the house where they are grown. There are both single and double of various colours.

FAIRY ROSE is a remarkable race of very small dwarf-growing Roses; they are sometimes called perennial, but may be treated as annuals. They flower within two months after the seed is sown, and are equally useful for the open border or for pot culture. They may be used for the edging of beds of dwarf Roses; each flower continues a long time in bloom, and is sweet scented. They may also be used for filling up any spaces on the rockery where early spring-flowering bulbs have been grown.

LAVIA ELEGANS.—A Californian annual, bright yellow edged with white. There is also a pure white variety of it called *alba* which is very effective. About 1 foot in height, very useful for cutting, and remains in bloom a long time.

PORTULACAS.—This is an old and well-known annual, and not nearly so much grown as it ought to be. It is one of those plants which a poor soil suits; indeed I have seen when grown at the edge of a border scatter its seed on the gravel walks, which the following year is made gay with its striking flowers, which vary from white to rose and magenta. It is essentially a sun lover, and will not open in dull and cloudy weather, but everyone who sees it in proper condition is at once taken with its brilliancy. It only grows to about 6 or 9 inches in height.—D., Deal.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES' AWARDS.

WHEN first I looked over the Royal Horticultural Society's report for the past year, and specially as an interested member of one of the Committees, which in one important paragraph are, to some extent, obviously reprimanded for their somewhat lax liberality in the granting of certificates, medals, and other awards, I did not notice the very important part the Council itself had played in the granting of those awards. There were held during the past year nineteen meetings at the Drill Hall, and six at Chiswick—a total of twenty-five; and be it primarily understood that at all these gatherings everything sent for show or for growth is so sent especially to secure an award of some sort if possible. Added to these there were the two huge national exhibitions of flowers at the Temple, and of fruit at the Crystal Palace, so that altogether there were twenty-seven occasions for the making of awards, and be it again remembered not by one Committee, for so wide is the ground covered by the Royal Horticultural Society, that no less than five separate Committees, comprising some 150 persons, have power to make awards. The total of awards of every description made by these bodies, or by sets of judges selected from them, was 873, made at twenty-seven shows or meetings.

Now the Council of the R.H.S. as a Council, and this is the reprimanding body, went to the great provincial shows of York and Chester last year, and they made awards of thirteen descriptions at these two shows, the total being seventy-five. With respect to these awards, the Committees as such had absolutely nothing to do. But look at the singular disproportion! Were the Council's liberality on these two occasions to be followed by the Committees generally we should see the year's awards total up a long way higher than was the case last year. That being so, would it not be well for the Council, before it attempts to advise the Committees again, to show these bodies a good example in forbearance by granting awards at these provincial shows with less liberal hand? It is not precept, but example that is so useful in such cases.

After all is there the slightest probability that any checks will be put on the present, perhaps too free, granting of awards? I fear not. I have long contended that in many directions it is now time that higher standards of excellence were set up, and I think generally, though not in every case, those standards are more exacting so far as certificates are concerned. That it is so in the case of the Fruit Committee is evident, because that body granted six only last year. The award of merit is the honour

most lavishly bestowed, for no less than 352 were given all round. Yet in this case I am disposed to think that the recipients set a far higher store upon it as an honour than it deserves. At the best it indicates very good average merit and no more, and that is not much to boast of. Often no doubt the award is good-naturedly bestowed, but so long as awards of merit are sanctioned so long will they be freely given. Very much no doubt are they given on the principle that they please someone and nobody is hurt.

It is said that the greatest criminals in the matter of awards are the Floral and Orchid Committees. I think it is not too much to say of the latter body that it is largely composed of pure enthusiasts, who are in their awards guided by no such severe considerations as animate members of other committees, and every trifling variation in form or colour or marking in any Orchid excites the greatest admiration; hence the abundance of awards. Possibly the purposed subjecting all honoured flowers to the ordeal of the artist's brush—and it is hoped the work of illustrating these flowers will be performed with absolute accuracy—for presenting to the Committee fac-similes of previous exhibits, and tend to somewhat cool members' fervour in relation to minute divergences henceforth.

With respect to the Floral Committee, if that body be specially chargeable with *laches* no one seems to trouble to defend it. Perhaps the members think its reputation is safe in the hands of its Chairman, who was not a member of the Council when the paragraph in the report I comment upon was indited. In any case, it is fair to say that the number of exhibits placed before that body, whether in the form of things for certificate or for medals, is vastly in excess of what comes before either of the other Committees.

I attended the recent general meeting specially in the hope that the President in his annual address would show some way or lay down some principle by which the Committees might be guided in making awards in the future. That seems to me to have been what the Council should have done, or otherwise have, beyond publishing the table of awards, made no further reference to it. I was also disappointed that no Fellow referred to the subject at the meeting, and that fact indicates indifference with every desire to see much higher standards in relation to awards prevailing, for they are now far too cheaply bestowed. Yet I cannot see, without the Council take action and formulate some definite rule, how any reform is to be effected.—ALEX. DEAN.

FORCING VEGETABLES.

(Concluded from page 135.)

ASPARAGUS.

NATURALLY this choice vegetable is more esteemed than Seakale with most people, especially by the majority of cooks, and I presume more satisfactory results are obtained in cooking this than Kale. The plan usually adopted, and which I do myself, is to make up a hotbed with fresh leaves and stable manure, two parts of the former to one of the latter. This should have been thrown together previously, and turned over a few times to sweeten it. The Asparagus will stand more heat top and bottom than Seakale. But this must not be much above 60°. A sheltered place should be chosen, but where plenty of light and sun can reach the bed. In putting the material together it should be well trodden, as this helps to retain the heat for a longer period. The bed should be a trifle higher at the back, especially if the frame at command has not a good angle, and space allowed for lining all around the frame. In fact, it should (the bed I mean) be made 18 inches larger each way than the frame to be placed upon it, so that the lining can be renewed when necessary.

When the frame is placed upon the bed, 3 or 4 inches of short manure or rough leaf soil should be put into it in readiness to receive the roots as soon as you ascertain that the heat is safe to do this. A test stick should have been placed in when the hotbed was made. If, after a week or ten days, when you withdraw the stick and can comfortably hold it in your hand without finding it too hot all will be well. It is far better to be on the safe side, as one can always add heating material in the way of lining. In fact, such a winter as we had up to Christmas, a bed of leaves only would be enough. Now, the next thing to see about is the crowns. These should be not less than three years old, but can be much more, and an advantage no doubt, as the crowns should be larger. They should be lifted and placed in the frame with as little delay as possible, putting the roots thickly together and placing about 4 inches of sifted leaf soil over the roots and crowns, and when all is finished there should be 6 to 9 inches clear of the glass. This will give room for the "grass" to grow.

The lights can be kept closed until you see the heads appearing, when a little air should be given on all favourable occasions, according to the state of the weather, which will assist in giving a green tint to the grass, and which should be cut when about 6 inches in length, tied in bundles of fifty, and stood in a little water if not required for immediate use. The frame must be well matted every night in case a frost should occur. And, again, I say, do not neglect to see to the lining. I usually start my first batch about the 15th of November, but this season it was on the 20th, and cut on December 7th, just eighteen days. My frames are 6 feet by 8 feet, and I fill one of these. It takes about eighty crowns. But as with Seakale, more or less, must be the grower's motto according to his requirements. I continue to cut from this first batch just one month. In the meantime the second frame had been planted—namely, December 18th, or four weeks from the first batch, and I find this is quite often enough. It is not necessary to make a new hotbed each

time. A renewal of lining and move up the inside of the bed is all that is necessary as a rule for two or three batches.

Those who are fortunate enough to have a pit (lean-to) with a 3-inch hot-water pipe running along the front can use this with advantage, and if there should be bottom-heat pipes all will be right. If not, new leaves with a little manure will give enough heat for this if placed in the bottom. Here, again, the temperature should not much exceed 60°, or the grass will be spindly. Very little water will be required during the dull months of December and January, a syringing occasionally will generally suffice unless hot-water pipes supply the bottom and top heat, when more will be necessary, and this should be at a temperature of 75°, when none will be required in the hotbeds until the sun has more power. Later batches, say from the middle of March, can be brought on in a cold pit that has been recently filled with fresh leaves during the winter months, the sun at this date being no mean factor. Some gardeners introduce a few batches into a vinery that may be started early in February, but I do not consider it's a good plan; it appears out of place, and I do not think very good results are obtained, there being nothing like a little bottom heat for this delicious and easily forced vegetable.

KIDNEY BEANS.

This is another acceptable vegetable early in the year, but I find from experience that unless one has good light and well heated houses, satisfactory results are not obtained by sowing much earlier than the new year, and in a temperature of 60° to 65°, with a rise of 10° by sun heat. It will take about seven weeks to have them fit to gather from the time of sowing, 8-inch pots are the most suitable for the first few batches. Some sow as early as August, so as to carry on without any break after the plants in the open ground have ceased bearing, but during November and December, generally dark, dull months, the returns are not very satisfactory. I think the end of December, or early in January, is soon enough. Seeds should be sown every three weeks or a month. Plenty of light is necessary for this vegetable, or they get drawn up very soon. They require to be kept fairly near the glass, and do well on shelves. The syringe must be constantly moved among them whenever the weather is favourable, if not they soon fall a prey to that horrid pest, red spider.

A fairly light, though rich, soil is necessary; loam, leaf soil, and a little manure from a spent Mushroom bed forms a good compost. The pots should be filled to within 3 inches of the top and made fairly firm, and about ten seeds sown in each pot, and covered with 1½ inch of soil. If all the seeds come up, one can easily thin them out to six, which will be enough to leave. I generally pinch out the tops as soon as the first pair of proper leaves are formed, which causes them to throw up two growths. They will take a fair amount of water at this stage; in fact, they must never be too much on the dry side or spider will soon appear. As soon as they are from 4 to 6 inches high some twiggy shoots should be placed around them as a support. Old worn-out birch brooms are useful for this. When in flower they should be kept rather drier overhead, and a circulation of air is beneficial at this stage.

As soon as they are set some kind of manure should be given them two or three times a week. I find a little weak guano water, also diluted farmyard drainings, suit them very well. They should be well syringed morning and afternoons, when closing time arrives. The beans, as they become fit, ought to be gathered and tied up in small bundles, and their ends stood in water until you have enough for a dish. Ten and twelve-inch pots can be used after the month of February is past, and they do not dry up as fast as the smaller pots. Boxes, too, are often made use of for later crops, about 2 feet 3 inches long, 9 or 10 inches wide, and the same in depth. These crops can be brought along in Peach houses or the like, while many gardeners have to grow them in their vineries; but I must say I do not like them brought in here in case that foe of ours I have spoken of makes its appearance. Heated pits, similar to those I mentioned anent the Asparagus, make excellent places to grow them in when sown in rows 15 inches apart. A crop can also be hastened a few weeks by sowing in a frame or cold pit, and shut up early in the afternoons and well syringed and matted up at night. Ne Plus Ultra I find very good for forcing, and Canadian Wonder for the latest hatches.

POTATOES.

These are forced in several ways. I find 9 and 12-inch pots suitable for a few early dishes. I place one tuber in the smaller pot and two in the larger one. Loamy soil, with a little horse droppings, makes a good compost. I start a batch early in January, and place them in an early Peach house at work. The tubers should have been previously prepared—that is, stood on their ends in a box with a little leaf soil scattered among them, and placed in the house about ten days before. These must be placed in their pots when 2 inches of growth has taken place. They must be given plenty of light, also air, when at all favourable, and I keep moving mine from house to house, Peach or vineries, as they are started, because they do not like too much heat. I leave room in the pots for an earthing up, as it were, when they get about 6 inches high.

Frames placed on a hotbed make a very suitable place too, and most excellent crops can be grown here. A foot of soil should be placed in the frame, and the tubers planted 5 inches deep, 8 inches apart, and 10 inches from row to row. I also make a point of earthing mine up with 3 inches of soil when about 6 inches high. This assists to keep the growths upright. Here they will take a fair amount of water when in active growth, and the lights are drawn back altogether very mild days, but placed on early in the afternoon and matted each night. Heated and unheated pits, too, are useful for forwarding this ever-required vegetable. As I have already said, they must have abundance of air as the season advances, and when water is necessary it should have been

warmed to about 60°. I ought to add that I only advocate the pot method for the very earliest dishes. Mine in the pits follow these, and are usually planted about the 20th of January. I find the Old Ashleaf, Veitch's, Myatt's, and Rivers', Sharpe's Victor, and Early Puritan good for forcing, but I prefer the first and last named varieties.

CARROTS.

This is another acceptable dish, and much appreciated when in a young state, and may be brought on much earlier than it is possible to have them outside by making up a bed of leaves and placing a frame thereon. What they require is similar to Potatoes—a gentle lasting heat, which fresh collected leaves will give. The frame should have about 9 inches of soil, which should be light and of a sandy nature, leaving space of 9 or 10 inches for the tops. The seed can be sown in drills 4 to 6 inches apart or broadcast. I adopt this last named plan, and it should not be sown too thickly, for if it is thinning must be done very early, as they soon get crowded. The frame can be kept closed until the seeds germinate, when a little air will be necessary whenever the weather will permit. The lights can be drawn off altogether when mild and replaced about 3.30. If bright, lightly syringe the bed, and then close up and replace mats as long as cold weather lasts. I do not think there is much gained by sowing until the middle of January. Parisian Forcing or Sutton's Early Gem are suitable for this work.—
[Paper read by Mr. J. MAYNE, Bickton, at a Meeting of the Devon and Exeter Gardeners' Association]

THE ROYAL GARDENERS' ORPHAN FUND.

ANNUAL MEETING.

THE annual meeting of the above charity was held at Anderton's Hotel on Friday last. Amongst those present were Messrs. W. Marshall (in the chair), W. Poupert, B. Wynne, G. W. Cummins, J. Lyne, W. Bates, G. Reynolds, J. Walker, F. Assbee, A. W. G. Weeks, and H. J. Jones. After the usual preliminary proceedings the Chairman moved the adoption of the report and balance-sheet, which is appended below. The motion was seconded by Mr. Fraser, and carried without any dissension.

In presenting their ninth annual report the Executive Committee can heartily congratulate the subscribers on another year's operations—generally satisfactory and encouraging.

If the financial support given to the Fund as annual subscriptions be not as large as the Committee could desire, yet from other sources it is evenly maintained and the interest in the progress of the Fund widely felt.

The Fund was instituted in 1887 in commemoration of the Jubilee of Her Majesty the Queen.

The year 1897 finds your Committee assisting in commemorating the

longest reign of a British Sovereign, and in consideration of this auspicious event they recommend to the subscribers that the whole of the candidates be elected by resolution of the annual meeting.

To those who have so generously, and in not a few cases, so constantly supported the Fund by means of special donations, the Committee owe a great debt of gratitude. By sums derived from money boxes, concerts, the opening to the public inspection of gardens and plant houses, especially during the season of the Chrysanthemum, the sale of flowers, &c., considerable additions have been made to the Fund.

The annual festival dinner—presided over by His Grace the Duke of Bedford, the President of the Fund—proved a most gratifying success, resulting in a considerable augmentation to the charity; and the Committee tender to His Grace their most grateful thanks for his able advocacy of the claims of the institution and also for his generous contribution. Among other contributions to the Festival Fund was that of the tenants of, and growers of produce for Covent Garden Market, who subscribed the sum of £341 15s. 6d., a measure of support highly appreciated by the Committee; and they also desire to gratefully acknowledge the great assistance rendered by Mr. J. Assbee in obtaining this welcome gift.

The number of children who have been placed on the Fund since the commencement is eighty-five; of this number fifty-eight are now receiving the benefits of the Fund, to be increased by those recommended for election this day. The number of children who through the age limit and other causes have ceased to be chargeable to the Fund is twenty-seven.

One most pleasing cause of gratification to the Committee is the letters of deep and earnest thankfulness received from the mothers of children who have ceased to be chargeable to the Fund, acknowledging the great help the quarterly payments have proved to them in times of necessity.

The Committee, by means of the special grants they are empowered to make, have also been enabled to render timely assistance in starting several orphans in life.

The total amount paid to the children since the commencement of the Fund is £4918.

The members of the Executive Committee who retire by rotation according to Rule IV., are Messrs. Marshall, Bates, Dean, Herbst, Jones, May, Reynolds, and Weeks, all of whom being eligible offer themselves for re-election.

The best thanks of this Committee are due, and are hereby tendered to the Treasurer, T. B. Haywood, Esq., and the Auditor, John Fraser, Esq., who retire after holding office since the establishment of the Fund. The Committee have great pleasure in announcing that N. N. Sherwood, Esq. (a munificent supporter of the Fund), has kindly consented to accept the office of Treasurer, and Peter Barr, Esq., that of Auditor, and they are hereby nominated by the Committee.

Mr. A. F. Barron is again nominated as Secretary at the same remuneration.

(Signed) PETER BARR
M. ROWAN, CLAPHAM } Auditors.

Dated, January 23rd, 1897.

It was proposed by Mr. Assbee, and seconded by Mr. Reynolds, that a hearty vote of thanks be accorded to the retiring Treasurer and Auditor, Messrs. T. B. Haywood and J. Fraser. Mr. B. Wynne then moved that Mr. N. N. Sherwood be appointed Treasurer in the place of Mr. Haywood. This proposition was agreeably accepted, and carried unanimously. On the proposition of Mr. Walker, and seconded by Mr. Reynolds, it was agreed that Mr. Peter Barr be elected Auditor in place of Mr. J. Fraser. Mr. Poupert moved that a vote of thanks be given to the retiring members of the Committee, and that they all be re-elected. Mr. Cummins seconded the resolution, which was carried unanimously. On the proposition of Mr. W. Marshall, seconded by Mr. R. Dean, Mr. A. F. Barron was duly re-elected Secretary to the Institution.

Mr. Marshall then moved that in order to commemorate the Diamond Jubilee of Her Most Gracious Majesty the Queen, the whole thirteen children who were presented to receive benefit should be placed on the Fund without election. He congratulated the Fund on being able to do this, stating that during the ten years of its existence nearly £5000 had been spent in charity, and that they had been able to put away for future use a sum of £10,000. Mr. J. Lyne seconded the motion, which was carried without dissension. It was further agreed that a copy of this resolution should be sent to Her Majesty and also to Her Royal Highness the Princess of Wales. There being no other business to transact, a vote of thanks to Mr. Marshall for presiding brought the proceedings to a close.

ANNUAL DINNER.

At the dinner held in the evening between twenty and thirty were present, Mr. Owen Thomas presiding. The Chairman's speech was a happy one, and proved how thoroughly he had entered into the details of the charity, and how truly he was the cause at heart. He said:—It only seems like yesterday when we were celebrating the Jubilee year of Her Majesty's accession to the throne. It was on this occasion when gardeners, like other loyal members of the community, were looking out for a way to give expression to their loyalty. It occurred to Mr. Penney, then of Sandringham, and Mr. Clayton of Grimston, that the best way this expression could take would be by forming an institution to befriend the orphans of gardeners, and I cannot but think that both these gentlemen will always look back with feelings of thankfulness for the inspiration that came to them to support the institution of this Fund. At first the idea was met by many with misgivings, as being too great an undertaking to be successfully launched. However, there were a few bold spirits in those days, and the prospect was no sooner mentioned by the gardening press than it was taken up with acclamation, not only by horticulturists but also by the garden loving public, and the proud position the Fund occupies to-day proves beyond doubt that a happier or a better suggestion could not have been made.

So much for the reception of the Fund. What shall be said of its growth? The excellent report in the hands of members will tell them much better than I can; but I may be allowed to say this, that nearly £5000 has been paid to destitute orphans of gardeners during the past nine years, besides a sum of £9000 which has been invested for their future benefit. This is a record to be proud of, and the management is to be congratulated. This great success has been brought about in the first place, I think, by virtue of the merit of the Charity, Gardeners' Orphans.

The English people have a garden, and they have opened their hearts and their pockets wide to help the objects of this charity. We know that our happy and favoured country is full of benevolent and kindly feeling towards the weak and the destitute, but it is not everyone who has the power or the happy faculty of being able to bring this good quality into active existence. The Orphan Fund is happy in having those at its head who take an active personal and practical interest in its welfare. When it is said that at the head of the charity we have the honoured and much-loved name of H.R.H. the Princess of Wales, with His Grace the Duke of Bedford as President, our esteemed friend Mr. Marshall as Chairman of the Executive Committee, with our old friend Mr. Barron as Secretary, besides a working Committee of gentlemen, everyone of whom is a well-known horticulturist, it is not to be wondered at the success which has attended the establishment of the Fund. We must not forget that the establishment of this Institution has imposed a serious responsibility on the shoulders of those who are responsible for its management and maintenance.

To-day there have been added thirteen orphans to the benefit of the Fund, at an extra annual expenditure to the charity of £170. A better commemoration of Her Majesty's long reign no institution could possibly make, and in view of this greater responsibility and greater income must be forthcoming, or the Fund will be in the same position as the orphans are now in—namely, with *No provision*. Gentlemen, if you will look down the list of orphan candidates for election, you will find the melancholy words, *No provision, no provision*, repeated over and over again. To me these words express a feeling of utter despair and desolation as represented in the case of the widow and destitute orphans. It means to these not only an empty chair, but an empty cupboard, an empty grate, and, often worse than all, an empty heart. The object of this charity is to help to ease the widow's burden, and to brighten the path of the orphan child. The wealthy lovers of gardens and gardening, as well as members of the horticultural trade, have come out nobly to help the garden charities, both this one and the older charity, in the welfare of which most of us are deeply interested.

It is with regret, and I say pained regret, that the fact must be stated that gardeners generally have not rallied round and identified themselves with the welfare of the garden charities as they ought. I do not know why; it is not from the want of kindly thoughts and feelings, I am quite sure, and I do not think it can be from the want of 5s. a year. Let each of those who does not subscribe answer for himself this eventful year in the best of all ways, by sending to Mr. Barron his subscription. What we want is for both the garden charities to become in reality national garden charities, to embrace the name of every gardener worthy of the name throughout the land, so that those who do not support the charity will be the exception rather than the rule, as at present. Gentlemen, we must gratefully acknowledge the valuable and increased help given by our earnest and kind friends in the provinces, and on their continued valuable help must largely depend the future welfare of this charity.

But the greatest source of our strength as regards the future must, I think, lie with the rising generation of young gardeners. To make it easier for them to join the Institution may I suggest, if your rules will permit of its being done, that you reduce the subscription to 2s. 6d. a year, and if this can be done I would ask every gardener who has the interest of the charity at heart to bring the subject before his young men, and I am sure a liberal response would be the result. This would open an easy door of entrance to the young, and once you secure his interest and sympathy you may depend upon it that in the great majority of instances he will prove a steadfast friend and supporter of the charity, and at the same time become a much better gardener.

It cannot be too well known that this is a purely benevolent institu-

tion, and that no question is asked as to the nationality of the candidates, or of what religion their parents may have been. Neither are the orphans debarred from the benefits of the Fund if the fathers in their lifetime have neglected to support the Institution. At the same time I cannot help saying that I would not give much for that man's love or care for his wife and children who refuses to do what he can whilst in health, on the funds of which those who are near and dear to him may be compelled to throw themselves through death or misfortune. Gentlemen, I ask you to drink to the "Continued Success and Prosperity of the Royal Gardeners' Orphan Fund."

CALLISTACHYS LONGIFOLIA.

I CANNOT understand why so many of the beautiful hardwooded plants have been allowed to slip out of cultivation. *Callistachys*

FIG. 37.—CALLISTACHYS LONGIFOLIA.

longifolia (fig. 37) used to be a special favourite of mine, but I have not seen it for years. It should be more generally grown. It blooms during the summer. The leaves are lanceolate, mucronate, some 6 inches long, smooth, dark green above. The standards of the flowers are yellow, and the wings purple. When properly treated the plants are extremely beautiful, and ought to be more frequently seen in gardens.

TADCASTER PAXTON SOCIETY. — On the 18th February Mr. W. Callum, B.A., head master of Tadcaster Grammar School, read a paper on the "Flora of Bygone Ages." He first reviewed the history of the earth from its incandescent condition through its successive stages of igneous and sedimentary rock formations. The flora of the carboniferous period was dealt with in detail. A rich collection of fossils was afterwards inspected. A hearty vote of thanks was accorded the essayist by a very full meeting of the Society.—J. S. G.

CARNATIONS AT RANGEMORE.

(Concluded from page 121.)

THE large flowering house runs north and south, and is built according to the rake of the ground—that is, the house gradually falls to the south. It has a central bed and stages on each side. The Malmaisons occupy the south end division, and the tree varieties the northern portion.

A collection of these tree varieties is not aimed at; on the contrary, numbers of what are proved to produce good-sized flowers and are free flowering is the object in view. This is evidently the right and only method by which a profusion of flowers can be had during the dull months of winter. New varieties are tried, and if they come up to the standard of excellence required they are propagated and grown in quantity.

Very few plants of Miss Joliffe are grown, not because it is not sufficiently free but the individual flowers are not large enough. J. S. Rugus was producing some very fine flowers, and seems destined to push out Winter Cheer. President Carnot, a dark flower and very free, is a favourite, and preferred to Uriah Pike. Mrs. Leopold de Rothschild was also prominent, as well as many others. Germania added a charm to the whole, being grown in large quantities and carefully arranged amongst the other colours throughout the house. The whole of these plants were in 7-inch pots, the plants being dwarf, very healthy, and full of flower and buds.

These plants are evidently managed on two principles, Germania and varieties of this nature being grown differently from what may be termed the real tree varieties. The plants of Germania raised from layers were at the time of my visit being potted into 5-inch pots. The plants were arranged closely to the glass, and would be allowed to flower, afterwards transferring them into 7-inch pots, these being afterwards grown outside until September the same as the trees, and housed with them. The tree varieties are raised by cuttings, the first earliest batch having been rooted and potted singly; in fact, might be termed established in 2½-inch pots. These were arranged close to the glass—a feature very observable at Rangemore.

Many cuttings were in process of rooting. These are young short growths from the axils of the leaves of flowering plants, and were inserted in sandy soil in 2½-inch pots, five cuttings in each. These were plunged amongst cocoa-nut fibre refuse close to the glass in a very low house. The bottom heat ranged about 80°, and the lights were not kept air-tight, sufficient air being admitted to prevent damping. When rooted they are potted singly, and grown with the earlier rooted batch.

A little pinching is done during the early stages of growth to induce the plants to branch, but too much pinching is not practised. The young plants as they need more root room are placed into 5-inch, and when they require more root room into 7-inch, the size they flower in.

About the time they are ready for 7-inch they are placed outside during the summer, which largely accounts for the dwarf sturdy nature of the plants. For their provision, while outside, beds 3 or 4 feet wide have been formed by 10-inch boards, which are filled with ashes and the pots plunged during hot bright weather to prevent too frequent watering. Over these beds has been arranged a wood framing, sloping from the centre either way like a span-roofed house, but sufficiently high so that watering and any other attention the plants need can be done without the woodwork being in the way. During wet weather waterproof canvas is stretched over the woodwork to shoot off heavy rains. This is a capital plan, the plants having plenty of air and a fair amount of light, even when protected from heavy rains.

Firm potting is practised, the plants are given room to develop, and with careful watering, judicious feeding while in the flowering house, abundance of flowers result.—WM. BARDNEY.

THE YOUNG GARDENERS' DOMAIN.

R.H.S. EXAMINATIONS.

I HAVE read with considerable interest "Student's" notes and examples on the above examinations lately in the Journal, and I am sure all readers, especially we youngsters, should be very grateful to him for his valuable information on the subject. I am rather surprised, though, that no questions were given by the Society with reference to the numerous Latin and French names and terms so commonly used by gardeners. I should have thought that a few questions as to the meanings of some Latin phrases at least would have been set, if not a few French ones also. Our first ambition when we start on our gardening career is to know the names of the various plants, and we look on our superiors as veritable encyclopædias, they are so well acquainted with them. How much better if, instead of knowing only the Latin or botanical names, we also know the English meaning as well. There are many of our leading men who are well up in the majority of plants, Orchids included, as far as their botanical names go, but quite ignorant as to the meaning of the same. Not only does this knowledge of a little Latin assist us in nomenclature, but should we be at all interested in the science of botany, which all gardeners should be, the various terms as well as the sections of plants can be better appreciated and understood through it.

As to the French of course we do not get so much of it in our work, but still it is very useful in some cases. For instance, various kinds of fruits bear the French names, notably Pears. In the plant section a vast number of our best Chrysanthemums are French named. If we are pretty well up in French we can understand the meanings of all these names, and a great number of mistakes can be avoided as to

pronunciation and orthography. There is no doubt that it is a grand thing to be a good grower of plants, but still it greatly enhances the interest of work if their names are perfectly understood. I should think if the R.H.S. included a few questions in their examination papers pertaining to these languages as they are used by gardeners, it would be a stimulus for us to improve in this department.—GARÇON.

FREESIA REFRACTA ALBA.

THIS charming sweet-scented flower requires very simple cultivation, and forms one of the chief features each season. After the plants have ceased flowering they are gradually dried off, and the pots placed on their sides at the back of a cool pit protected from the wet. About the second week in August, before the bulbs begin to start, they are shaken out and potted in a compost of light fibry loam, leaf mould, and decomposed manure in equal proportions, with a sprinkling of sand. About twenty bulbs are placed in a 32-size pot, so as to produce a good mass of flowers and foliage. After being well watered they are set in a cold frame and covered with ashes until the foliage appears well above the surface. They are then taken out and placed on shelves in a cool house, the temperature being allowed to drop to 38° on severe nights. Weak liquid manure is given when the plants are well established. We have now 150 pots of Freesias, the plants just coming into flower, and these will be very useful for greenhouse and decorative purposes.—J. B., Eastnor Castle Gardens.

NOTES ON LAPAGERIAS.

HAVING read with interest for some weeks past "The Young Gardeners' Domain," I now venture to contribute a few notes on Lapagerias. In most conservatories some kind of creepers are required for the adornment of the walls and roofs, and I think Lapagerias may be placed prominently amongst them. The plants succeed best planted in a bed of good loam, with a little peat and silver sand intermixed. They commence making their young growths about the beginning of April, and when these are from 4 to 6 inches in length they should be carefully trained to the wires or trelliswork.

It is essential that the syringe be freely used amongst the foliage of Lapagerias on all bright days during their period of growth up to the time of flowering, which is usually about July. One special feature about this conservatory climber is the long time it continues to produce its beautiful wax-like flowers, even after most of our other creepers of the conservatory are at rest. We have Lapagerias in quantities from July to January. The flowers are very effective when used for table decoration, and are invaluable when wired for the making of wreaths and crosses. Propagation may be effected by seeds or from suckers, which the plants produce when in a thriving condition.—H. H., Staffs.

VICTORIAN ERA FUND.

WITH pleasure I read the appeal made by "Yorkshireman" to young gardeners in aid of this deserving Fund. I hope it will be met by hearty approval amongst the young men of our craft, and that they will give what they can, be it much or little. For my own part I will give one day's wage in aid of it, as no doubt many more will do for the cause which is to provide means for the aged and infirm to obtain the necessities of life in their declining years. Perhaps the days may come when some of us may stand in need of a helping hand; therefore the present time is ours to act, that those who follow in our steps may be encouraged to do the same.

A short time ago I read in the pages of the *Journal of Horticulture* a suggestion made by our esteemed friend "An Old Boy" "That he hoped if the Committee of the Gardeners' Royal Benevolent Society could see their way clear to admit young gardeners as members of the Society at an annual subscription of 10s. 6d. instead of a guinea until they filled a higher position."

This I consider to be an excellent idea, and I hope it may soon come to pass, as I am sure it will be the means of getting many young gardeners to join who otherwise would not. It is a Society which ought to have our support, so let us give it.—J. W.

IMANTOPHYLLUMS (CLIVIAS).

CLIVIAS are not grown so extensively as their good qualities deserve. They are among the most useful of plants for the decoration of the conservatory, and cut purposes also, during the winter and spring months. They are of the easiest cultivation, and will grow either in a stove, intermediate house, or a greenhouse. A temperature of 50° to 55° suits them admirably. Maintain a moist atmosphere during the growing season, and a moderately dry one when growth is completed. They require abundance of water during summer, and will be greatly benefited by frequent applications of liquid or artificial manure.

Some of the new varieties are marked improvements on the old typical *miniaturum*, as for instance *Mdlle. Marie Reimers*, orange scarlet; *Distinction*, brilliant orange scarlet; and *Splendens*, dark orange. The trusses and flowers are larger, brighter in colour, and more refined and attractive in every respect. Where plants of small size are required they may be grown in 6 or 7-inch pots. By this means we produce a succession of flowers, instead of having large numbers at one time on one plant.

Clivias grow well in a mixture of good fibrous loam and leaf soil, incorporated with coarse silver sand. They should not be overpotted or disturbed unnecessarily, otherwise they will not flower satisfactorily. When the tips of the foliage show signs of decay the plants should be examined and repotted, or they will soon present an unsightly appearance.—C. W. M.

GLORIOSA SUPERBA.

THIS is a stove climber, than which I think nothing looks more handsome on a roof when the plants are in bloom. The colour of *G. superba* is a deep rich orange and red, the flowers hanging from 10 to 12 inches from the stem of the plants. The cultivation is very easy, and the following soil I have found to do exceedingly well—namely, good fibrous peat, light loam, good leaf mould, and spent manure from old Mushroom beds in equal proportions, with the addition of some small charcoal and lime rubbish.

After the tubers are potted, the soil being in a proper working order, no water will be required before they have started into growth, after which a good moist heat is necessary. The syringe must be requisitioned, or the leaves may get smothered in thrips and red spider, which will quickly spoil the beauty of the specimens.

When the season of flowering is past they should be gradually dried and placed on the shelf in a colder house until they are required for starting for the next season. This *Gloriosa* can also be grown from seed, the seed being placed singly in small pots, which must be plunged in a close frame. I have also seen the seed vegetate on the ashes in which the plants were stood on in the stove, and some of these plants were also potted, and made good tubers for the following season.—W. L.

PRIMULA OBCONICA.

I THINK this valuable greenhouse plant is often looked down upon as being unworthy of cultivation, but in my opinion a freer and a more easily cultivated plant does not exist. The old-fashioned system of procedure is to divide the old plants in order to obtain a fresh stock, the results of which seldom give satisfactory results. A much better way is to sow seeds about the middle of March in a light compost; prick the seedlings, as soon as they are large enough to handle, into thumb pots or shallow pans, eventually transferring to other pots as the plants require it. A good compost to grow them in is formed of two parts fibrous loam, one part of leaf soil, and half a part of sharp sand, with a good dash of wood ashes.

After the pots are well filled with roots liquid manure, made of the excreta of fowls, and soot will greatly benefit the plants if given occasionally in weak doses through the growing season. Through the summer all buds that appear must be picked off until the end of October, when the plants may be allowed to flower, which they will do without cessation right through the winter. The flowers stand remarkably well, both for house and table decorations. Facilities do not always exist for growing forced flowers in large quantities, and in such cases one cannot do better than raise a number of *Primula obconica* from seeds, so as to have a good supply of its charming lilac-white blooms through the winter.—ANXIOUS, G. H.

CYCLAMENS.

THESE are among the most useful of all our autumn, winter, and spring-flowering greenhouse plants. With good treatment plants may be had in flower from September till March, which makes them worthy of more extended cultivation, especially where there is a demand for cut flowers in the winter.

The best time to sow the seed is during the month of August, in well-drained pots, in a compost of fine loam, leaf mould, and sand in equal parts. Cover the seed pots with a square of glass to preserve moisture and protect the seeds, and place them in a temperature of 60° to 65°. When the seedlings appear remove the glass, and place them on a shelf to prevent their becoming drawn. When large enough to handle they should be pricked about an inch apart in pans, using the same compost as advised for sowing, but not quite so fine, and kept in a similar temperature till spring.

About the month of March they should be placed in 3-inch pots, using a compost of two parts loam, one part leaf mould, and one part old Mushroom bed refuse, with sufficient sand to keep it open, and maintain a temperature of 55°. When these pots become full of roots shift in 5-inch pots, in which they will flower admirably, this time adding a little fertiliser to the soil. During the summer months they do best stood on ashes in a cold frame, keeping them well shaded from the sun, syringing lightly every afternoon of bright days.

Never allow the plants to get dry during their growing season. I have seen the foliage turn yellow and the crowns go blind through not having sufficient water. When the pots become full of roots weak liquid manure once a week, or a light sprinkling of artificial manure on the surface once a fortnight, is essential. Give all the air possible to promote sturdy growth, and keep the plants free from green fly by frequent fumigations.

Cyclamens may be grown a second year by drying moderately and resting the corms for a time after they have finished flowering, afterwards reducing the soil and repotting. They should then receive similar treatment to that previously advised for young plants.—AN ENGLISHMAN IN SCOTLAND.

NOTES FROM A COFFEE ESTATE.

THE following extracts, which I hope may interest many and supply wished-for information to others, are from the letter of a late bothy mate, now on a Coffee estate in British Central Africa.

"The estate consists of over 2000 acres lying at an altitude of 3500 feet above sea level, has two streams on it, and is for the most part covered with trees from 20 to 50 feet high. Bamboos and Palms abound in the streams. The flora is very fine. I have discovered a few Orchids, Ferns in abundance, *Gladiolus*, *Amaryllis*, many creepers, and a host of other gorgeous flowers. Any European fruits introduced here seem to

do well. We have wild Figs, Bananas, Pine Apple, Papaw, Guava, Lime, and others; guinea fowl, buck, hartebeeste, sable, pigs, and zebra, besides the larger and fiercer beasts; a host of snakes. . . .

"With a few 'boys' (we have had 500 at a time) we cleared half an acre for nursery and put in Coffee seed to plant 150 acres—1200 plants per acre. The seeds take nine weeks to germinate, growing slowly at first, then coming away with a rush.

"The houses are of the mud and wattle style, built by inserting stout poles 2 feet apart for walls, to which bamboo are lashed with fibre, and mud plastered inside and out. The outside mud is taken from the ant hills, there being many about, and as large as an ordinary house. . . .

"We mark out plantations of from 2 to 18 acres, cutting down trees and carrying them off to the sides, afterwards lining off in beds 6 feet by 6 feet, using pegs of bamboo. Pits 2 feet deep and 18 inches wide are made for each seedling. We plant in the rainy season—November till March, hence hoeing and weeding, gathering the crops, and storing is all that is required. There is no successful system of manuring. Some planters use shade plants, one to every four or six others, thus minimising disease and insuring more regular crops.

"The workers get from 4 to 10 yards of calico (3d. per yard) wages, and 4 yards 'food' cloth per month! They engage for terms of from two to six months. At sunrise the horn or lapenga is blown to start the boys. . . .

"May till November is the dry season, November till April the rainy season. We had frost last June—June and July being the coldest months. I could get you a large collection of beautiful insects."

Thus do they labour in another sphere
To produce for us what we cannot grow here.

—A YOUNG SCOT.

HARDY FRUIT GARDEN.

Fruit Trees on Grass.—The present is a suitable time to establish fruit trees on grass. Standards are the most common form of trees sought after for this purpose. Until, however, the trees are growing freely the soil immediately surrounding them must be kept free from both grass and weeds. It is important that they be securely staked, owing to the more generally exposed positions such situations present. The stems must be protected from the attacks of animals.

Preparing Sites and Planting.—In preparing the positions for planting excavate the soil 6 to 9 feet in diameter. The top spit of soil should be thrown out and the bottom broken up, adding to this portion a layer of decayed manure, forking it in. Return the soil which was thrown out, intermixing with it, especially if heavy, some gritty material or burnt refuse. Insert a strong stake in the centre sufficiently long for the purpose of binding the tree to. Plant closely to it, spreading out the roots in a wide hole of shallow depth and slightly convex shape. Fold some soft material round the stems, securing the trees to the stakes with copper wire. Large standard Apples and Pears ought to be 30 feet apart, standard Plums and Damsons 15 to 20 feet apart.

Preparing Soil and Planting Raspberries.—Raspberries delight in rich soil. Before planting, thorough preparation and enrichment of the soil is essential to obtain the best results. It may be desirable to trench the ground, and this will afford an opportunity to incorporate manure freely. It must be well decomposed. It will not have the effect of promoting growth too luxuriant in character, as it would have, probably, in the case of most other fruits. Though the Raspberry is mainly a surface rooter, yet strong primary roots descend to a considerable depth, and assist in supporting the plants, also encouraging the free production of suckers. Of the latter those which do not ramble away from the line of the clumps or rows give the strong canes, a limited number of the best of which are annually retained for the future bearing.

Training.—Raspberries may be planted in rows or clumps. Rows should run parallel to one another at a distance of 4 to 6 feet between. Strong robust varieties may be planted the wider distance, and the plants in the rows given a clear space of 2 feet. Clumps must be planted 3 feet apart in rows 5 or 6 feet asunder. Place three plants 6 inches apart in triangular form with a stout stake in the centre. When the plants are established the canes are shortened annually to the height of the stake, and round it they are tied. The canes in the espalier method are best tied to wires strained between stout posts 3 inches thick fixed at each end of rows.

Treatment after Planting.—The first season, however, after planting the canes ought to be cut down close to the soil in order to encourage the vigorous production of new ones. By sacrificing a crop, which could only be a light one, the first year, the plants are fully established for the next and succeeding seasons. A manurial mulch over the roots will assist in maintaining the ground uniformly moist.

Pruning Cob Nuts and Filberts.—The catkins are very conspicuous on Cob Nuts and Filberts at the present time. They depend from the upper parts of shoots and side branches, and are plentifully supplied with pollen, which flies about in clouds when the catkins are shaken by the wind or otherwise. The female blossoms are situated below, being inconspicuous buds with crimson styles. These should be fully developed, and the catkins have distributed their pollen before pruning is attempted. Thinning out and regulating may be the first point attended to. The centres of Nut bushes are best kept open. The permanent branches must not be allowed to crowd one another. The side shoots may be pruned to various lengths. Some are left long in order to retain the catkins if the latter are still wanted; others which may be fruitless prune closely in. Short, stubby shoots or twigs having a blossom bud at the extremity require no pruning. If the bearing shoots of the year previous still remain numerous some may be shortened closely in. The buds left will furnish shoots for future bearing. Shorten the leading shoots of established trees to two or three buds. Younger trees must have the leaders shortened according to their strength. Weak growths ought to have two-thirds cut away. If of moderate strength half their length may be left, while strong shoots are better with only one-third removed. The pruning induces the formation of side shoots the following year, which should be fruitful. Cut out old or exhausted branches, utilising well placed shoots from the base to take their place, also remove suckers and useless spray. The production of suckers is detrimental to the trees if allowed to remain. By these means the bushes can be kept sturdy and fruitful, because abundance of light and air can reach every part.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest House.*—The weather has been generally favourable to forcing operations, it not having been necessary to have recourse to sharp firing, and the trees in consequence look well, and the crop so far satisfactory. A night temperature of 50° to 55° and 60° to 65° by day artificially, advancing to 70° or 75° from sun heat, especially after closing, will keep the trees in steady progress. Ventilate from 60°, increasing with the sun heat, taking care to avoid cold currents and sudden depressions of temperature, which cripple the foliage, and may cause the fruit to fall. Syringe in the morning and afternoon with water of the temperature of the house, and always sufficiently early to allow the foliage to become dry before night. On dull days omit the afternoon syringing, also the morning when cold and sunless, damping the borders and paths instead. Inside borders must be duly supplied with water, affording liquid manure to weakly trees. Disbud carefully, and in accordance with the growth. When this is strong the whole of the foreright shoots may be taken off at once, and some of the side growths pinched back to form spurs on the extension, but not on branches that will be removed after the fruit is gathered, retaining the best break from the base of the several shoots now bearing, and this must have room for extension with full exposure to light, and a shoot must be reserved on a level with or above the fruit to attract the sap to it, pinching such, when not required for extension, at the third leaf, and to one afterwards as made. Trees that have set heavy crops of fruit should have the least promising removed, especially those badly placed or on the under side of the trellises. To help weakly trees afford top-dressings of fertilisers at intervals of about three weeks, and wash in moderately.

Second Early House.—The trees started at the new year have set the fruit, and syringing will need to be resorted to after this is effected, which will assist them to cast off the remains of the flowers. Syringe, however, cautiously in dull cold weather, as it only weakens the growths, and has a tendency to induce wood formation at the expense of the fruit swelling. A night temperature of 50° is safe in severe weather, and 55° by day, 5° more in mild weather, with 5° to 10° rise from sun heat. Disbud gradually and carefully, practising it when the fruit is fairly swelling, and when begun follow it up a little each day. Where there is a thick set of fruit remove the smallest and worst placed by degrees. Attend to the inside borders as required for watering, avoiding making the soil sodden and sour.

Trees Started Early in February.—In the house started this month the flowers are well advanced, and should be closely examined for aphides. If any are present fumigate with tobacco or vaporise with nicotine essence, having the trees dry, and let it be moderate, or foliage may be crippled and the crop ruined, repeating on two or three consecutive evenings. This will keep the trees free from the pests until the flowering is over. When the anthers show clear of the corollas cease syringing, maintaining a genial condition of the atmosphere by damping the paths and borders in the morning and early afternoon. Turn on the heat early in the morning to secure and maintain a temperature of 50° by day, ventilating from 55°, allowing an advance to 60° or 65° from sun heat with a free circulation of air, employing fire heat only at night to keep the temperature between 40° and 45°. Where there is a great show of blossom remove that on the under side of the shoots. Supply water to the border if it needs moisture, remembering that a very wet soil induces sappy growths.

Houses to Afford Fruit in Late July and Early August.—These should be started early in March, syringing twice a day until the buds show colour, when it must cease. Maintain a temperature of 50° by day, and with ventilation from that point an advance may be made from sun heat to 65°; 40° to 45° is ample at night. If the border is at all dry afford an adequate supply of water, repeating as necessary. Where the

blossom buds are superabundant remove those on the under side of the trellis, drawing the hand the reverse way of the growths. Fumigate if there be the least trace of aphides.

Latest Houses.—These are often unheated and have the roof-lights fixed, both great mistakes, as the buds swell early, and there is little more safety for the blossoms in a cold wet spring than outdoors. With the roof-lights off the buds are quite dormant, and they need not be replaced until the buds commence swelling freely. Under fixed roofs ventilate freely, and where there is heat merely exclude frost. Heat is essential in cold localities, as the blossom is not safe from spring frost, and the fruit does not ripen perfectly if the season be cold and sunless. Besides, a gentle heat during flowering does much towards securing a good set, and in autumn artificial heat is necessary to ripen the fruit and wood. Indeed, the very late varieties cannot be depended on to produce good fruit in late localities without aid in backward seasons, and some of the latest sorts are noble in appearance, good in quality, a gentle heat making great difference in the fruit as regards its thorough ripening. See that the borders are well supplied with moisture. Those having been exposed are thoroughly moistened through to the drainage, and will not require watering until the fruit is advanced in swelling; besides, such trees never cast their buds when they should be developing their flowers.

Vines.—*Early Forced in Pots.*—These require generous treatment, such as surface dressings of rich material, well-decayed manure, and lumpy loam, with a sprinkling bone superphosphate and copious supplies of liquid manure in a tepid state, keeping the plunging material about the roots well moistened with the same to insure the spread of the roots into it and augment the support of the Vines. With the roots coming over the rims and from the bottoms of the pots the Vines make plenty of foliage, which should not be kept too closely pinched, as there is nothing like plenty of feeders to secure well-swelled berries.

Early Houses.—Planted-out Vines started early in December have the Grapes swelling and approaching the stoning period; they will require careful treatment in ventilating, affording a little air at 70°, increasing it with the sun heat, keeping this through the day at 80° to 85°, closing by or before the temperature recedes to 80°, and if it advance to 85° or 90° all the better. Avoid cold draughts; they are prolific of rust and cripple the foliage. Keep inside borders well supplied with water or liquid manure of the same temperature as the mean of the house, and maintain a genial condition of the atmosphere by damping the paths and borders two or three times a day, especially at closing time.

Grapes in Flower.—The temperature ought not to be less than 60° to 65°, with a rise of 10° to 15° by day. Lessen or discontinue the syringing, though moderate humidity is desirable for the benefit of the foliage, preventing condensation of moisture by a little ventilation constantly, taking care not to cause a draught. Shy-setting varieties require careful fertilisation, all varieties well repaying the labour by producing finer bunches of evenly formed berries. Afford Muscats in bloom a night temperature of 65° to 70°, and 10° to 15° rise by day; if the bunches are numerous a better set will be secured by the removal of the surplus bunches before they flower. Duplicate bunches only take support from those left for the crop.

Thinning Grapes.—Keep this operation well in hand, thinning Black Hamburgs and other free-setting varieties as soon as possible after flowering, but the shy setting Muscats and others should be left until the properly fertilised berries can be distinguished by their taking the lead in swelling. Thinning requires the exercise of a little judgment, taking the character of the kind and capabilities of the Vines into consideration. Sufficient berries should be taken out to allow those left to attain their full size without wedging or crushing, retaining sufficient to prevent the bunches falling out of shape when cut and laid upon the dish.

Succession Houses.—Attend to disbudding as soon as the best breaks can be discerned, proceeding gradually. Stopping may take place one, two, three, or four joints beyond the show of fruit as the space admits, but the more leaves beyond the fruit having exposure to light the more certain is it of being well supported. If the space is limited stop at the second joint, or even at one beyond the bunch; but if the room admits stop the growths at the third or fourth joint beyond the bunch, and then allow the laterals to extend until the available space is covered with an even spread of leaves, then keep closely stopped. Tie the growths down before they touch the glass, bringing them down carefully, as the growths of vigorous Vines are liable to snap. Allow plenty of room in the ligatures for the swelling of the shoots. When the bunches show increase the temperature to 55° to 60° at night, 65° by day artificially, 70° to 75° from sun heat, and an increase of 5° to 10° from that source after closing.

Late Houses.—If late Vines are not yet cleared of Grapes it should be done at once, pruning the Vines and dressing the cuts with best French polish or styptic, shellac dissolved in alcohol being excellent for this purpose; and cleanse the house and Vines, removing the loose surface soil from the border, supplying fresh loam, keeping the house as cool as possible. Examine Grapes in rooms, removing any decayed or mouldy berries, as one soon spoils a whole bunch. Maintain the temperature at 40° to 45°, and the room being dry the Grapes will keep sound and give little trouble. Muscats, Lady Downe's, and other late varieties, from which the Grapes were cut about the new year, may now be encouraged to grow, as the Vines starting early in March have a chance to mature their Grapes thoroughly before the cold and sunless

autumn weather, and the fruit keeps much better ripened not later than early in September, late ripened fruit being in every way less desirable. The inside borders must be brought into a thoroughly moist state by the application of water at a temperature of 80°, following with rather thick but tepid liquid manure when the Vines are weak or been heavily cropped. The outside borders will only need the protection of a little rather short litter to prevent chill from frost, cold rains, or snow. If the Vines in any case are planted outside, their stems must be well wrapped in haybands, otherwise the Vines will suffer in periods of sharp frosts.

THE FLOWER GARDEN.

Erythrina.—A bed wholly planted with these in variety present when in flower a unique appearance, and they are well adapted, filling isolated beds in pleasure ground or for using with sub-tropical plants. In some positions the old stools may be wintered in the open, a covering of leaf soil, ashes, or cocoa-nut fibre refuse being all the protection needed. As a rule the safest plan is to lift them and store on a dry floor in a cool house. If started in heat they will form numerous shoots which, when about 3 inches long, may be taken off with a heel attached and placed singly in small pots filled with sandy, peaty soil. Plunge in a brisk bottom heat, cover with hand-glasses, and dry the latter daily to prevent damp attacking the cuttings. *E. Crista-Galli* is the most commonly grown, and if seed of this can be procured a stock of plants can soon be raised. It must be first soaked similarly to Canna and Acacia seed, and the subsequent treatment may be identical.

Eucalyptus globulus.—Though not generally hardy, a few young plants are of service for mixed beds and partially filled shrubberies, the glaucous foliage contrasting well with darker shades of colour. They can only be raised from seeds, and these should be sown now thinly in pans of sandy peaty soil, and duly plunged in a brisk bottom heat, a square of glass placed over the pans hastening germination. The seedlings may first be pricked out thinly in pans, or placed singly in small pots, being eventually shifted into 5-inch or rather larger pots. They may be grown to a good size prior to planting out, but the plants are not so effective in the first season as they are when kept in pots and placed out early in the following May.

Ficus elastica.—Where sub-tropical bedding is carried out on either a large or small scale the "Indiarubber Plant" ought to be freely used either in mixed beds or grouped thinly, having a showy groundwork to display them to the best advantage. Old conservatory plants introduced into heat will soon afford a number of cuttings. Every leaf with a short length of wood attached will root, but the progress of these plants is slow, and side shoots are preferable. First take off the top of the main stem and strong branches, preserving three nearly or quite fully developed leaves, and cut to a joint below these. Dry the wounds with the aid of dry silver sand, and insert firmly in the centre of small pots filled with light sandy soil. Fasten the leaves uprightly with the aid of a light stake and raffia, plunge the pots in a brisk bottom heat, cover with a bell-glass, and avoid overwatering. The side shoots when about 5 inches long to be taken off with a short slice of old wood attached and treated similarly to the tops. All ought to be kept growing in gentle heat and given one shift, being eventually hardened prior to planting or plunging in the open in June.

Hollyhocks.—A packet of seed obtained from a reliable source contains a good per-centage of showy varieties, but those who wish to flower them this year must lose no time in procuring and sowing it in a pan of fine sandy soil. If this is set on or plunged in a gentle hotbed and covered with a square of glass the seedlings will appear in a fortnight, and these being gradually exposed to more light and air may first be pricked off carefully into other pans of soil and kept growing in gentle heat. Before they crowd each other they ought to be placed singly in small pots and gradually hardened. While in a cool pit or frame the strongest ought to be given a shift into 5-inch pots, and it is these which under further liberal treatment will form fairly strong flower spikes. All should be planted out in May, or before they become badly root-bound. Even the smaller plants will frequently flower in a favourable season. Seedlings are less liable to disease than are those obtained by rooting side shoots much as Dahlias are increased.

Narcissi.—These may safely be lifted, divided, and replanted at the present time, provided the weather is sufficiently mild. If this is done carefully, the tender roots not being much denuded of soil, and not injured by cold winds, the removal will not interfere with the flowering either in this or the next season, whereas bulbs transplanted in a dry state frequently fail to flower in the second spring following. Clumps of the common Daffodils lifted in the woods and planted near the stems of Apple trees are greatly improved by the change, and fine masses of flower annually result.

THE BEE-KEEPER.

DOUBLING HIVES.

If "G. H." will give the doubling system a fair trial in comparison with others he will have no cause to be disappointed at the result. At present he does not quite grasp the idea, and imagines more hives will be necessary than when larger hives are used, and nucleus hives are required for queen rearing, whereas in practice it is quite the reverse. I will endeavour to make the matter plainer.

It is a fact well known to all bee-keepers who have studied the question that bees are not at all particular as to how and where they store a surplus if extra space is provided for them when they require it. It is also immaterial to them whether the space is narrow or wide, but if left to themselves I am inclined to think they would choose a small insignificant place for their dwelling, quite out of keeping with our modern ideas of bee-keeping.

We must not forget that it is quite possible for "G. H." or anyone else who understands the management of bees to obtain as good a sample of honey from an ordinary box or zinc skep, if placed on the top of a strong colony of bees, as from the most elaborate hive. It would, however, not be in as convenient a form for handling as when obtained in either deep or shallow frames. For this reason it is advisable to endeavour so far as it is possible to have the bees under perfect control and the necessary appliances conveniently situated.

On referring to my notes, extending over a series of years, as to the exact time the majority of my hives have been doubled, or more properly speaking, placing a box, which may be termed a super, on my hives, has been more often done during the last week in May than at any other time. If the bees have wintered well, and the spring has been genial, many of the hives will at that time be crowded with bees, and if the quilt is lifted off they will boil over the sides of the hive in thousands.

A stock of this description will not require any assistance from other colonies, as there will be quite enough brood and bees to fill the double hive when the honey flow comes some three or four weeks later. Four or five frames of brood are then taken from the brood nest and placed in the top storey, being replaced with empty combs. The queen being provided with extra room will fill the frames from top to bottom with brood, and there being a sheet of excluder zinc placed between the brood nest and super, all surplus will be carried to the top, and the vacant space, not being taken up with the frames containing brood, may be filled with frames of tough combs that will not break down in the extractor.

If many stocks are kept there will be a great difference in their strength at that season. But as it is necessary to have all hives intended for extracting purposes crowded with bees when the honey flow comes, it is an advantage to obtain bees and brood from other hives. These weakened stocks are then used for queen rearing, and as early queens are invariably the best, if worked on this system they are fertilised and laying before the end of June. Two or more queens may be raised in each hive. This is done by placing a division board across the middle of each hive. I can confidently recommend this plan to gardeners whose employers may object to having too many hives on their property. If there is a surplus to be obtained by any means, depend upon it stocks treated on rational lines as above will obtain a share.

LARGE HIVES.

These I have used holding from twelve to twenty and even more frames (standard size). Someone may say "What is the standard size?" It is 14 inches by 8½ inches (outside measure). These, however, require somewhat different management from smaller hives.

The ordinary hive holding ten frames is not contracted in the winter, but one having space for twenty frames is better if reduced to half that size for wintering purposes. This is done by placing the division board between the frames, which may be left to the back of dummy, often keeping in better condition and free from moths than when packed away in boxes. As the brood nest expands in the spring the division board may be moved back and a fresh comb brought forward every two or three days as required. Hives holding fifteen frames are quite large enough for all practical purposes, and similar treatment is required whether they are intended for sections or extracting.

If the former is desired, as soon as the hive is crowded with bees, and honey is coming in somewhat freely, place a crate of sections on the top, covering them up warmly. As soon as they are three parts filled place another crate of empty sections under

them, and manipulate them as advised for other hives. For run or extracted honey use shallow frames 14 inches by 5½ inches. If the colony is a strong one and the weather favourable the bees will commence to work in them at once. There is, however, a danger of them swarming if only a single crate of shallow frames is used. It is therefore advisable to place another crate of shallow frames under the former before they become sealed over. As soon as this has taken place the honey may be extracted and the empty frames placed under the others to be again filled. But for reasons previously given I prefer a smaller hive.—AN ENGLISH BEE-KEEPER.

MICE IN BEE HIVES.

LAST season I had a large number of bees and hives to look after from various causes, the chief one illness of the owner, who had no less than six apiaries in different localities. In each case I found mice had seriously interfered with if not destroyed colonies. In one case of a bar-frame hive last autumn, which had not been overhauled except to put on a crate of sections, I found at least a quarter peck of Plum stones, the kernels of which the mice had eaten. These stones were wedged and propolised by the bees, so that I had to lift several frames together bodily to do anything with them. The top portions of the frames were fairly filled with honey.

I attributed the cause of these attacks chiefly to the fact that few of the hives were on legs, and many simply standing on a brick at each corner of the hive, and being practically on the ground, the mice thus gaining easy access and gnawing a hole at a corner of the entrance. In one case, on taking off a cover, I succeeded in killing five mice with my hand. But mice should be trapped in the neighbourhood of hives—in the hedges if near hives. They are the long-tailed field mice which do the damage, and also spoil rows of Peas and Beans.—J. HAM, *The Wren's Nest, Astwood Bank.*

TRADE CATALOGUES RECEIVED.

J. Laing & Sons, Forest Hill.—*Clivias.*

Letellier & Son, Caen, France.—*Gooseberries.*

Surrey Seed Co., Redhill.—*Seeds.*

* * All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Book on Landscape Gardening for Bothy (G. W. B. G.)—Kemp's "How to Lay Out a Garden" is the most practical work on the subject, but out of print, though sometimes procurable at secondhand booksellers. Milner's "Landscape Gardening" is a more elaborate and expensive work, with excellent engravings, but we do not know the price or publisher. What you require is a less pretentious work than either, of which we do not know, nor is any likely to be issued, as the sale would be very questionable as regards meeting the cost of production.

Melons in Frames (One Desirous to Know).—The treatment of Melons is very similar to that practised with Cucumbers. The soil, however, should be rather heavier in character, and the growths kept somewhat thinner. When the laterals appear from the principal growths select a limited number for extending. They show fruit at the second or third joint. As many of the pistillate flowers as possible ought to be fertilised at one time. Of the fruits which swell select those equal in size. Limit the number on each plant to four or six. In frame culture means must be taken to supply plenty of heat. Avoid watering too closely to the main stem. Should canker appear rub in quicklime. Maintain the soil moderately moist, and the leaves fully exposed to light. Stop the bearing laterals two joints beyond the fruit when the latter is set. The night temperature should be 70°.

Peaches and Nectarines in Pots (Anxious).—These fruits cultivated in pots in a cool greenhouse, require no syringing previous to or during the flowering stage. The atmosphere of the house should be kept dry and free ventilation afforded, especially in the middle of the day. At that period the pollen, when the flowers are fully open, will be perfectly dry, and distribute itself freely when the trees are lightly shaken. This usually insures fertilization; but a more certain method is to gather perfectly dry pollen from the anthers of fully expanded flowers with a camel-hair brush, and apply to the stigmas of the flowers. A regular moist condition of the roots must be maintained from the time the plants are housed. Trees in pots are placed outside after the fruit has ripened.

Size of Boxes for Cut Flowers (H. W.)—We have sent cut flowers over 300 miles in a varied assortment of boxes of both tin and wood, and have found nothing better than deal ones about 18 inches long, 12 inches wide, and 2½ deep, all inside measure. We used these singly or as trays in a box of two or three tiers, one fitting closely on the other and the lid tight upon the uppermost. The thing is to pack so that the flowers do not move, hence we had elastic passed through holes in the box bottoms so as to form loops inside crosswise, and the stalks of the flowers being placed in them they could not move in transit. This gives a little extra trouble both in packing and unpacking, but the flowers come out as fresh as when sent off, and were satisfactory to everyone concerned.

Lime Mixed with Soil for Cucumbers (J. B.)—We are unable to account for the lime killing the plants unless it was of a very caustic and deleterious nature—a poison. It seems strange that the compost containing the largest amount of lime should only remain four days, the medium ten days, and the smallest twelve days before use. Why there should be such difference passes our understanding, and if that were recommended by the learned professor named we do not wonder at your having a dread of "supposed" remedies. No such advice has been given in the *Journal of Horticulture*. Our turf for Cucumbers is cut in the late summer and the lime mixed with it in stacking. We have found the practice excellent in reducing the herbage and destroying the larvæ of any pests it contained. We have never had any eelworm in either Cucumbers or Tomatoes grown in it.

Black Hamburgh Grapes Breaking Stronger at Top of Rods than Bottom (A. W. E. E.)—The Vines ought to have been depressed before the buds at the lower part of the rods or canes commenced swelling in each year, the upper part being brought down lower than the bottom of the rafters or base of the cane or rod, and so have remained until the buds on the lower part of the Vines had pushed, securing the canes or rods in position as soon as that was effected, and before the shoots had grown in a wrong direction. We have frequently depressed young canes to an angle of 45° in order to make the buds break strongly at the base, and have raised them a little at a time so as to get an even break throughout the length of it. This is more simple to do than to explain, and is more a matter of judgment than anything else, which you will no doubt exercise according to circumstances.

Pear Tree Infested with Scale (F. M. M.)—The potash and soda wash to which you allude is made by dissolving 1 oz. each of caustic soda and commercial potash (pearlash) in hot water, say a quart, and when dissolved adding hot water to make 1 gallon of solution. This, when of a temperature of 130°, is to be applied with a half-worn painter's sash tool, properly cleaned, and in such a manner as to wet every part of the tree, not using it carelessly so as to run down and cause injury to the roots. The solution must be applied whilst the buds are quite dormant, and to be effectual the hack as well as the front of the branches should be reached. For spraying the solution is made stronger; ½ lb. each caustic soda and commercial potash to 6 gallons of water for Apples, Plums, and Pears, using at a temperature of 130°; and for other trees, such as Apricots, diluting to 8 gallons. In treating wall trees it is difficult to reach the back of the branches without unloosing them and applying with a brush, hence the slightly modified formula.

Keeping Carrots Through the Winter (Nemo).—The best means of keeping Carrots is to pack them in sand in an outhouse, so that each root will be separate and not form large piles, 18 inches to 2 feet being sufficiently high, the sand being only moderately moist, and covering used during frosty weather. This appears to be the practice you have followed, and have suffered from to the extent of losing half of the roots. We have found Carrots keep well in a shed or outhouse, with only sufficient dry straw on them to exclude frost. As for the other plan—namely, pitting them in the open, a large farmer growing vegetables for market and supplying them direct to the consumers adopts that system, the pits being narrow (about 2½ feet) and low (about 1 foot 9 inches) a dry site being chosen, the usual covering of dry straw employed, and then sufficient earth placed on so as to exclude frost. The plan answers well in most seasons—not always, for unless the Carrots are matured before lifting, this being done in a dry time without bruising or injuring the flesh, and the covering but light at first, so that sweating cannot take place, or if taking place allow the moisture to pass off, the Carrots will not keep for any length of time. Keeping, therefore, depends on thorough maturity, cleanness of roots, freedom from damage, with moderate dryness and safety from frost. Some gardeners leave Carrots in the ground, covering the surface thickly with leaves, and claim for the roots better quality than those which are stored.

Tomatoes for Outdoor and Indoor (Cambs).—The varieties you name, Earliest of All and Perfection, are excellent and when well grown produce abundance of fruit, the latter being found among the majority of prizewinning dishes at exhibitions. Everything, however, depends upon the cultivation, though, of course, this is no use without suitable varieties, which are mostly selections, and on that account improvements on the older and less carefully selected varieties.

Cheapest and Best Coping for a Vinery Wall (T. W. M.).—The cheapest and the best coping we have used for garden walls and horticultural structures was Portland cement—one part to two parts sharp gravel screening, small gravel, and sand, forming into a mortar-like mass, then placing in the trough. What you mean by a coping half an inch less than the wall plate we do not understand, as a coping means covering a wall and projecting over it on both sides. But if a capping is meant, we may say that concrete—if by that a cement one is intended—will not injure but preserve woodwork, if it fits close and excludes wet.

Pruning Tea Roses (Rosa).—Recently planted Roses require to be somewhat more closely pruned than established plants, cutting the weak shoots to one or two buds, medium to three or four, and strong to five or six. Very weakly and ill-placed shoots are best cut out altogether, so as to give advantage to the best situated and strongest. The pruning is to some extent a matter of judgment, and must be exercised according to the condition of the plants, aiming at vigorous growth without over-luxuriance, so as to secure fine blooms and make provision for their production. Outdoors the Roses should not be pruned until the end of March, no harm being done if they make a little growth, so long as the basal buds are not started. This will prevent injury from late spring frosts, and give finer Roses.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (L. W. C.).—Your Apples are probably local seedlings that never had recognised names; all are inferior in quality. The Pear is not in a fit state for naming. (J. H. O.).—1, Bramley's Seedling; 2, Warner's King; 3, Golden Winter Nonesuch. (C. R.).—1, Easter Beurré; 2, undeterminable; 3, Cox's Orange Pippin; 4, King of the Pippins; 5, unknown; 6, Wellington.

LARGE v. SMALL FARMS.

PARTISANS are often bitter. Our own ideas are so large as to entirely obscure our mental vision. We have no room to see the good points in the cause of others, and we do not care to hear views advocated at variance with our own.

It requires a broad mind to impartially consider an opponent's proposition. That this is so is a pity, but, alas! it is human nature, and we are not quite sure of a remedy. Education will not do it, for it is often that we find educated people with a very strong bias. The only remedy seems to be beyond book learning proper—the mixing with and studying mankind at large. A cosmopolitan is generally a man of broad views. He sees life from many standpoints, and if an honest man is only too glad to admit the wisdom and cleverness of others.

There has been much written and said on the subject of our paper ("Large v. Small Farms"). Both have their advantages, both their disadvantages; but we doubt whether a panacea for agricultural depression is to be found by cutting up large farms into small ones. First there is the primary cost. Take a large holding; we find a good house and range of suitable buildings in the centre. The house cannot well be sub-divided, and unless a tenant can be found out of agriculture the house will probably be long on hand, and no property depreciates so quickly as empty houses.

Of course in some neighbourhoods such a place will let quickly, say to hunting or shooting men, or to retired officers who prefer the quiet of country life; but these houses must be fairly near railway and sport, and a farmhouse, however good, in a remote region is practically unlettable. Then this necessitates the erection of smaller dwellings with the proper out-buildings, and the estimate of such buildings on a 20 acre plot cost £20 or £25 per acre as against £8 per acre on the well-arranged large holding. Capital has to be found for this, and to meet this outlay higher rent must naturally be demanded.

So many people fail to grasp the fact that these small holdings must, to make them a paying concern for the landlord, be let at higher rent than one large occupation. The division of a property into small lots increases the cost of management, but there are good people quite blind to this. They have never seen the inside of an estate office, nor have they any idea of the machinery that keeps all in order.

Of late years we have had to complain of severe agricultural depression, a depression arising from two causes—badness of the

seasons and low prices. Now the seasons we cannot alter, all we can do is to make the best of whatever weather comes, and strive by extra labour to meet the exigencies of the case—take advantage of any temporary change, and never waste a minute.

As to prices, well this is a wide subject, and many "savants" shake their heads, but we are of opinion there is a little hope of better things, much rests with ourselves. Can we lessen the cost of production? The easiest way to do that is to have a clever capable man on a large holding, with a well equipped complement of labour-saving appliances.

A mixed occupation seems to afford a partial solution, and on that class and on tillage farms more stock can be raised than on the very best purely grass farms, and stock is now our sheet anchor. A large occupier has the best means of attracting the best class of labourers—a good wage, comfortable house and garden, and in most cases labour is an inheritance. We hear of little change, men are kept on from year to year, the masters know the value of faithful service, and the men the value of regular well-paid labour, to say nothing of the kindly feeling existing between the big house and the small cottage. We have men in our employ whose term of service exceeds twenty years, and we hope we are far from the end yet. Men of this class are great factors in making a farm profitable.

Now another item. Stock must be well fed, and the "menu" is a long one. An engine for grinding, pulping, chaff-cutting, water pumping, soon pays for itself. On some farms a portable threshing engine is hired; with it should be used a chaff-cutter, and as the straw is threshed it should be cut and stored. Two extra hands will do this well, and save much time and further expenditure.

As long as cereals are cheap we are greatly in favour of grinding home produce. Straw, too, may largely take the place of hay; but to obtain the greatest nutritive value this straw should be cut before being dead ripe; and as peat moss is so generally used as litter, and with, as our cow man says, the best results, there should be plenty of straw for stock. The large farmer, too, has a great pull over the small one in another respect—*i.e.*, the closer supervision of labour. It pays to have good foremen; a master cannot be everywhere, and working hours are short.

The large farmer still needs much in the way of better protection for his stock, but this is being remedied daily. Take a small holder. His capital does not allow him to purchase the desirable amounts of feeding stuffs and tillages, and often, poor fellow, through very ignorance he gets robbed buying the cheaper article, which a little education would tell him was fearfully dear in the long run. He knows nothing of buying on analysis, and he is a ready prey to the first unscrupulous "muck" merchant he meets.

As to labour, not wanting it all the year round, he has to take men who delight in "catch work," and are not very fond of that. He has no labour-saving appliances; he works day and night to achieve what his richer neighbour can accomplish in half the time; his head of stock, too, is small, and a loss among it is severely felt. We were very sorry for one of these small men the other day, who told us all his corn had been spoilt by the wet harvest (he was on a Carr farm—good land, but backward), half his lambs had died, in a great measure from eating unnutritious grassy food, and his stock losses mounted up to £30 for about four months.

This was a man who had been a capital foreman—father before him, so valued by his late master that he had let him his little holding for life on most advantageous terms.

Where a small holding is most profitable it must be within easy reach of a good market, and the wife must be even a better manager in her department and cleverer than her husband; but at best, under most favourable conditions, the work is arduous, the pay poor, and with all the good will in the world the best is not made of the land.

WORK ON THE HOME FARM.

The weather has become mild and spring-like, the blackbirds are singing, and rooks are hanging around their old quarters in a way suggestive of nest-building at an early date. To farmers short of winter keep, which list practically includes a very great majority all over the country, the prospect of a mild and forward spring is most welcome. All that is now wanted is a cessation of the wet weather. Wheats have been almost living in water ever since they were sown. Such conditions are never favourable to the production of a robust plant, and on wet lands the plants look very wiry. On medium and dry soils, however, Wheat is looking well, and quite forward enough for the time of year. As soon as the land is dry enough it should be rolled, and as soon as the least sign of weeds is noticed a light harrowing must be given. Weeds are easily killed when small, but if they once get well established nothing but a hoe will really eradicate them. This is especially the case with the Poppy, a great pest on sandy soils, but easily killed before it attains its third leaf.

We see a few lambs about, but lambing is not general enough to give a report upon. Sheep have done fairly well on Turnips considering the very wet lair they have had. Many hoggs (hoggets) are being marketed now in the wool, which, if Turnips had been more plentiful, would have been clipped in April. Will this have much effect on the trade later on? It would twenty years ago; but now, we suppose, the foreigner will level up the supply.

A few more fine days and drilling of spring corn will become general on all but the lightest soils. Oats will soon go in well enough, but a warm and good seed bed is necessary for Barley if it is to do well. We should advise getting Oats in first, and letting the Barley wait for March winds and a more powerful sunshine. "A peck of March dust is worth a king's ransom," is an old saying among northern farmers; and it is no great exaggeration if the value of a dry seed bed for Barley is fully taken into account.

Work at the fences must be completed now as rapidly as possible, for the sap will soon begin to flow, and hedges cut too late are much weakened by undue bleeding.

We are killing our last pigs for curing. The first week in March is the latest date at which it is safe to cure anything but very small weights.

OUR LETTER BOX.

Liquid Manure for Grass Land (*Subscriber*).—The drainings of piggeries and cow sheds are excellent for grass land, but are very variable in value, as sometimes they are little better than water and at other times almost entirely urine. Of course, there is a difference in the mode of collecting, for when the tank can receive nothing but the neat drainings it will not vary so much as when washing or rain water also run into the tank. These are matters upon which we can form no opinion; therefore judgment must be exercised, for neat drainings will burn the grass unless put on when the ground is moist and during the prevalence of showery weather. In the case of such drainings and in ordinary weather we have found it necessary to dilute with two parts water to prevent browning the grass in summer time. In the winter time we used it neat, applying whenever the weather was mild, for it is no use putting it on when the ground is frozen, and the whole ground given a dressing in due course, or as far as it would go for the hay crop or grazing purposes before April. After that time it can only be used on grazing land, always in showery weather, or with an early prospect of rain. After hay cutting we have used it with considerable advantage, cows always preferring sweet to sour grass, and thrive better in every way.

REMARKS.

- 14th.—Overcast early, fine and generally sunny from 11 A.M. to 3 P.M., and cloudy after.
 15th.—Overcast, with occasional drizzle.
 16th.—High smoke fog all morning, clearing about noon; fair afternoon. Lunar halo at night.
 17th.—Bright sun all day, but slight smoke fog till about 11 A.M.; fine night.
 18th.—Bright sunshine throughout.
 19th.—Dull, drizzly and rainy all day.
 20th.—Continuous rain or drizzle till 11 A.M.; sunny in afternoon. Solar halo at 3.30 P.M.

A fine mild week, but with grass frosts on three mornings.—G. J. SYMONS.

VEITCHS'

SUPERB CAULIFLOWERS.

VEITCHS' EARLY FORCING.

First-Class Certificate, Royal Horticultural Society.

Of dwarf compact habit, beautifully close and white, medium-sized heads. Comes into use earlier than any other variety. Highly recommended for forcing or very early use.

Per Packet, 1/6 and 2/6.

VEITCHS' PEARL.

The best Main Crop variety, producing pure white heads of medium size and finest quality.

Per Packet, 1/6.

VEITCHS' AUTUMN GIANT.

The grandest variety in cultivation, magnificent, large, pure white heads, of splendid quality; indispensable for autumn use.

Per Ounce, 2/-.

For full descriptions of the above and other CHOICE NOVELTIES, see SEED CATALOGUE for 1897, forwarded Post Free on application.

JAMES VEITCH & SONS,
ROYAL EXOTIC NURSERY, Ltd.,
CHELSEA, LONDON, S.W.

ANT. ROOZEN & SON'S

CHOICE

VEGETABLE & FLOWER Seeds

FOR PRESENT SOWING,
AND

BULBS AND PLANTS

FOR SPRING PLANTING.

COLLECTIONS OF VEGETABLE AND FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM, HOLLAND, or to our General Agents,

Messrs. MERTENS & CO.,

NEW AND DELICIOUS MARROWFAT PEAS.

A POD OF CARTERS' DAISY.

CARTERS' DAISY.

The only Pea that embodies the best features of an ideal variety, viz.,

EARLINESS,
HABIT,
SIZE OF POD,
and FLAVOUR.

CARTERS' DAISY PEA

Is not a selection, but creates a distinct break in Marrowfat Peas.

Its merits have received recognition from the Royal Horticultural Society on more than one occasion.

DR. MASTERS, F.R.S., inspected our crop, and illustrated this remarkable Pea in the columns of the *Gardeners' Chronicle*.

HEIGHT, ABOUT 1½ FEET

New Hand-picked Seed in Sealed Packets,
Price 2s. per Pint;
3s 6d. per Quart.
Carriage Free.

CARTERS' NEW PEAS

have a distinct character peculiar to themselves alone, as witness the world-wide popularity of STRATAGEM and TELEPHONE, both of which were introduced by Messrs. Carter.

ANOTHER GRAND NOVELTY! CARTERS' MICHAELMAS PEA.

As its name implies, this fine Marrow Pea is of the greatest service as a "Last-of-All" crop. It was well grown last season in the Pea trials conducted by the Royal Horticultural Society, and the only late Pea considered worthy of their Award.

Height, 2½ feet.
In Sealed Packets, 3s. Pint;
5s. Quart, post free.

Illustrated CATALOGUE, Gratis and Post Free.

THURSDAY, MARCH 4, 1897.

THE SIMPLICITIES OF PRUNING.

IT has been my fortune to assist in training many youths in the art of gardening, and it has often seemed to me that the two most difficult lessons that beginners have to learn is to water plants in pots properly and to prune a tree rationally. Perhaps the latter task is the more difficult of the two, and it is surprising how completely lost young gardeners often are when set to prune a most ordinary tree or bush if there is no one at hand to guide them. This is mainly due to a failure to grasp the first principles upon which all good pruning must be founded, yet the difficulties are easily surmounted with ordinary care, attention, and intelligence.

Though somewhat late now for pruning hardy fruit trees in most districts, probably there are some not yet completed, and a few notes on what may be termed the elements of the art may render some matters clearer to our younger brethren. First it should be remembered what the object of the pruner is in subjecting a tree to such artificial treatment as removing a portion of its branches. The special desire is, of course, to promote fruitfulness, and this can best be accomplished by encouraging a balance of roots and stem growth. So long as there is an undue excess or deficiency in the vigour of either of these organs so long will there be unsatisfactory fruit crops or none at all. The branches are more completely under our control than the roots, although it is possible to bring these within our influence also, so we will first refer to branch pruning, as that is an operation that concerns the majority.

Before commencing the actual work it is necessary to be furnished with the requisite tools, which means sharp knives for all trees, a narrow saw in addition for large trees, and some also use and advocate the employment of the continental pruning scissors or shears—*sécateurs*. I have, however, tried various forms of the latter instruments, and have not found any design perfectly satisfactory. For small soft growths they will answer fairly well if kept properly sharpened and tightened at the screw, but when employed for cutting larger hard wood they give bad results even in

experienced hands. The bark and younger wood are crushed or bruised in a manner that greatly delays, if it does not effectually prevent the healing process, without which pruning is the source of many tree diseases or troubles. I therefore rely upon the knives for all hardwood pruning, and two essential points with regard to them is that a really good steel instrument be chosen to start with, and then that this be kept properly sharpened. It is a common mistake to put too short an edge on pruning knives when sharpening them, with the result that it is quickly worn off, very frequent sharpening being needed, or damage is soon done. The knife blade is held at too great an angle with the stone; it should be nearly level with its surface, as a longer, smoother edge is thus obtained, and the knife wears better and more evenly. An example of what is meant is afforded by scythe sharpening, though this is an operation that few young gardeners have to perform nowadays, but at one time no man had completed his initiatory experience until he could sharpen and use a scythe in a masterly fashion. A short edge on the blade is useless, and every good workman speedily learned the necessity of holding the stone at a very slight angle to the blade, so as to secure as long an edge as possible.

A good and sharp knife being therefore indispensable in pruning, the next matter is to use it in such a manner that a short clean cut may be produced, and not a long jagged wound. I have found it needful to repeatedly impress upon the minds of learners that the shorter and cleaner the cut the quicker and more certain is the healing, but there seems to be a natural tendency to make a long upward cut, and finish off with a ragged piece of wood or bark at the top. The due control of the knife in the hand is a lesson that must be learned by observation and experience; but with all smaller wood if the thumb of the right hand is placed immediately below the point where the shoot is to be severed, the knife can be drawn upwards without damage to the tree or the operator. Even in the case of larger branches it is preferable, wherever it is possible, to cut towards oneself rather than away, as there is less danger of the knife slipping into other branches, a prolific source of injury in the hands of the inexperienced and careless.

Where a branch or shoot is to be removed, it should be cut just above and towards a bud, but if the cut is started low too much wood is removed from the back of the bud, with the result that it often fails to start into growth, or does so in a very weakly manner, a lower bud probably taking the lead, which may be the means of throwing the tree out of shape. On the other hand, when the cut is made above the bud, and much wood is left, this frequently dies and leaves a "snag" that has to be ultimately cut away, and provides in the meantime a nidus for the eggs of insects. What is required is a short sloping cut from behind the bud forwards, leaving just sufficient wood to protect the bud from injury, an eighth of an inch being sufficient, and if closer cutting is attempted it is not uncommon to see the top of the bud sliced off.

In starting to prune a bush, pyramid, or standard fruit tree, whether young or old, it is most convenient to first determine what growth is useless or antagonistic to the future well-being of the tree. Branches that cross each other or crowded in the centre of the tree, and not needed for the due furnishing or shape, should be cut clean out close to the main branch or stem, not leaving a projecting piece or "snag" that may lead to a cankerous wound affecting the whole tree. The next point is to consider the shape of the tree, and for either pyramid or standard trees of any of our hardy fruits the determination of the "leader" is an important but not always an easy matter. With young trees several shoots often start from near the apex of the tree, and sometimes a lower branch is stronger and better placed for the leader than the upper and natural one. Occasionally it may in such cases be advisable to sacrifice the original branch, but it is a matter that must be regulated by the judgment of the pruner. The position of the bud to which the main shoot is shortened must be carefully selected, for this

determines to a great extent the direction taken by the following season's growth. If it is growing out the upright a bud must be chosen on the opposite side from that which was left in the preceding season; in fact it is well to make it a rule to cut to opposite buds each year. In all strong growing varieties this is essential to keep the stem central, as the growths will often start at a considerable angle with what may be termed the axis of the tree.

The position of the buds must also be considered in dealing with all the branches, as the shape of the tree is influenced most beneficially by a due attention to this, though it is a matter that is too frequently overlooked, and a branch is shortened without the slightest regard to the probable direction the bud left will take. To keep a tree of any kind open in the centre and well proportioned, outer buds should be always selected, those in a line with the direction of development for the main branches being selected. For others buds should be chosen on the side where there is the most space to be filled, and the only case where an upper or inside bud may be desirable is where a lower branch has extended beyond the radius of the tree and is too near the ground.

As to the length of wood to be cut away from any particular shoot or branch considerable judgment is required, but as a general direction it may be taken that the stronger branches need the least shortening, and the weaker branches the most, keeping in view the shape of the tree. Then as regards young Apple and Pear trees, to which these remarks chiefly refer, it will be found that for the first year or two from one-half to two-thirds of the length of the shoots will have to be removed, or even in some cases three-fourths may be cut away with advantage, though it seems like a sacrifice.

These simplicities will be found in experience to include the principal part of the art of pruning, and the essential qualities required for its successful prosecution—i.e., close observation and careful work are those which a gardener needs in every department of his calling.—PRACTITIONER.

CUCUMBER AND TOMATO TROUBLES.

(Continued from page 130.)

MORE confusion exists as to the causes of so many failures with Tomatoes than is the case with Cucumbers. Experts have had a fine innings. How they have revelled in their discoveries, and wallowed in their scientific phrases! What long chapters they have written in describing the symptoms and working out the progress of the diseases and insects they have found with the aid of a powerful microscope! They "hit it off" so minutely that the worried growers of the plants that have been submitted to examination think the remedy is at hand, and their worries are over. No such luck.

What does it all amount to? Pages of descriptive matter, and only a few lines of probabilities in the way of remedial measures. It is doubtless satisfactory to know that the "black stripe" has been scientifically dubbed *Macrosporium tomati*, also that the "sleeping disease" is known as *Fusarium Lycopersici*, and has its *Diplocadium* stage. But this is not enough; various other technical phrases, including *conidia*, *saphophytes*, *hyphæ*, *chlamydospores*, *zooglæa*, and the like occur too frequently. No doubt they are scientifically correct, and if they were not employed we "laymen" would not be sufficiently impressed with the ability of the writers. As it happens, most gardeners are plain men, and appreciate plain words. Above all things, we like to have something tangible, solid, and useful—not so much and so many learned and laboured intricacies, which aggravate our already disturbed equilibrium.

I propose to give my own views and experiences on the subject of Tomato troubles in a plain way. Private gardeners as a rule have little or no conception of the serious consequences attached to a bad attack of the drooping disease. They scarcely know what it means. If one-third of their plants collapse they need not worry; but, as it happens, their losses are infinitesimal, for reasons which will presently transpire. The case is very different with men who depend principally upon their Tomato crops to provide the wherewithal to support them and their household. When strong fruiting plants by the score or hundred droop suddenly never to recover, a scare naturally sets in, and if no remedy is found serious loss is entailed. It is the same with the "black stripe,"

"yellow spot" (*Cladosporium*), wireworm, and eelworm attacks. All these troubles I have had to face, and therefore am no stranger to the sensations they bring about.

If I remember rightly the drooping or sleeping disease and black stripe were at one time considered synonymous. The same cause was at work in both cases, only the effect differed. That theory appears to be exploded—rightly so, I think. Then a very minute species of eelworm, so small as to be invisible unless viewed through a microscope, was blamed for the drooping disease; but this view of the case does not appear to meet with favour among the savants. The ordinary eelworm causes galls to form on the roots, and is unmistakable; the invisible form was supposed to attack the collars of the plants, and so cut off the supplies of crude sap to the top growth—result, collapse. What particular form of disease or nematoid that eventually finishes up the plants I am unable to determine, nor am I greatly concerned about the correct nomenclature. What I do know is that no reliable remedy has yet been offered. Plenty of suggestions, nothing positive. Can I supply the deficiency? Probably, but not positively, till yet another season has passed. Is my presumable remedy expensive? No, nothing cheaper. With me the price is 10d. per 1000 gallons, and it is applied through a hose. Be sparing of water at the roots, and drooping plants will be seen by the score every day till such times as those surviving have reached the moister soil below.

Mr. Abbey is of opinion that "a dressing of quicklime, a peck per rod to soil where plants are growing, and as a winter dressing $\frac{1}{2}$ cwt. per rod, mixing it thoroughly with the soil to a depth of 15 to 18 inches, coupled with a careful selection of seed, is all that is necessary to avoid 'black stripe,' 'sleepy' or 'drooping' diseases as caused by *Fusarium solani*." That is positive enough, but, unfortunately, unreliable. Neither under glass nor in the open is lime really effective as a preventive. It may do good service from a manurial point of view, but was powerless as tried by me against the drooping disease. On the other hand, we have been repeatedly warned against employing solid manure, or that obtained from stables and farmyards, in Tomato culture. We have been told it must not be dug in, or the growth of the plants will be rank and disease-inviting; it must not be used as a mulch, as this would favour the spread of diseases of a fungoid nature. When a gardener can provide fresh turfy loam each season for the comparatively few plants he grows, solid manure is uncalled for in the soil, and might easily do more harm than good; but the case is very different with the market grower.

The advice is sometimes given to wholly change the soil in houses devoted principally to Tomato culture. Has it ever been practised by those offering this advice, or, say, more than once? Wheeling out the top spit from a house 130 feet long and 20 feet wide would be no light undertaking, and where is the soil to come from to take its place? We find it absolutely necessary, and are content to double dig the borders each season, bringing a little of the fresh subsoil to the surface, and forking in a liberal supply of half-decayed manure into the subsoil. Firmness in the soil is most desirable, and if other details are properly carried out there is little likelihood of the plants being grown too strongly. Not content with the manuring mentioned, suitable chemical manures are also forked in. Lime may be needed in some cases, though not oftener than once in five years, and scarcely then if superphosphate of lime is one of the manures forked into the surface.

So much for the preparation of the soil. We have next to consider what other preventive measures are likely to act beneficially. One experienced Tomato grower is a firm believer in corrosive sublimate. If he still finds this disinfectant effective he will render good service by again referring to it in these pages. Last season I spent 12s. on corrosive sublimate, and failed to see any gain thereby. We dissolved 2 lbs. of it, and diluted with 1000 gallons of water, about a week before planting the Tomatoes, and from first to last, no difference was seen in the behaviour of the plants treated to the corrosive sublimate and those which received none. Sleepy and diseased plants were fewer than usual in each case, thanks to the heavier supply of water. We also tried the effects of gas liquor, or ammoniacal water obtained from the gasworks. This appeared rather strong, and 35 gallons was diluted with 700 gallons of water. Perhaps we watered our liquor too much—"drowned" it, as the toppers say. Anyway, nothing noteworthy came of it. It was given what may be considered a fair trial, and I should have been glad to find it a good remedy, as it is cheap. Yet another large breadth of border under glass was watered with soluble phenyle at the rate of 1 gallon, costing 6s. (six shillings), to 160 gallons of water, and as this was an expensive experiment only one-half of a house was watered with it. Once more nothing very encouraging resulted. Evidently phenyle applied prior to planting is not a preventive of disease. Kainit we have used freely for the past four years, and it is an important element in any cheap and effective mixture of Tomato manure. If

it has the effect of stimulating root action then it contributes towards warding off disease; otherwise it cannot, in my estimation, be rightly classed as either a fungicide or insecticide.

Only in one long house were no experiments tried, and strange to relate the crops in that instance were second to none. Viewed with strict impartiality the only conclusion we could honestly arrive at is that no chemical or other preparations are of avail by themselves. If we starve the plants at the roots a few or many of them will fail. With us it has invariably been the most heavily cropped plants that were the first to succumb, and if we take into consideration the great weight of fruit each plant produces in proportion to the foliage ought we to wonder if they do break down under the strain? They must be kept constantly moist at the roots, and in order to save the watering pot or hose considerably a good mulching of strawy manure should be applied before the plants are far advanced. This serves to conserve moisture in the soil, to keep the atmosphere drier, and the roots active near the surface.

It will thus be seen I hold nearly the same views concerning the treatment of Tomatoes as expressed on page 130 in relation to Cucumber culture. By all means start with plants raised from seed saved from fruit grown on healthy plants. Build these up strongly and sustain them in their vigour by means of abundance of moisture and liquid manure applied to the roots. With plants, as with individuals, it is those weakly in constitution that break down the first if subjected to adverse influences. If in spite of all that is done signs of drooping and black stripe are observable, then lose no time in applying medicine in the shape of phenyle, using enough of this properly diluted to well saturate the already moistened soil about all the plants in that particular quarter or house. Altogether we used 6 gallons of phenyle last season, and consider we were well repaid for the outlay. There is so much yet to be said about Tomato troubles that I propose to again return to the subject.—W. IGGULDEN.

HARDY FLOWER NOTES.

THE time of the singing of birds has come, and with it the delights of the garden appear. The snow has vanished, and, though nights are sharp and chill, the warm sun by day lights up the glowing Crocus and spurs on the other early flowers. All around, while the great pulse of Nature hardly seems to beat, there are faint movements which show that she is beginning to wake from her winter's sleep. The trees still stand gaunt and leafless, their great limbs and traceries of twigs casting happily little shade 'twixt us and the sun. The hedges are bare and still unclothed with their greenery, but the Willows, though leafless still, are dressing themselves with their silvery knobs—their infant "Palms"—that glisten in the February sun. In the garden the borders still look bare without their towering or lowly plants in leaf, but there are shoots astir and pointing through the dark earth. Nor are these all that tell us of the uprising of the flowers, for already the more daring have come and are hastening away.

The Snowdrops no longer hang their pure flowers eardrop-like from their flexile stems, but in wanton mood spread out their petals to woo the bee to explore their blooms in search of hidden store. The pale gold cups of the Winter Aconite look faint and dim beside those of the deeper yellow Crocus which joyously greets the welcome sunlight. The early Irises unfold their graceful petals to charm the gazer as he passes by. The yellow Crocus has found companions of other hues. Imperati's one acts as rival to the Snowdrop in her attractions for the bees, but not unaided nor unrivalled itself, for the Scotch Crocus with its honeyed odour draws to its white blooms many of the winged foragers.

The early azure Grape Hyacinth (*Muscari azureum*) shows its blue cones amid their attendant leaves, and the Spring Meadow Saffron, as *Bulbocodium vernum* is called, is about to make a brave mass of violet-purple flowers on one of the rockeries. About to do it, we say, but ere this is in type it will be in full beauty. The Winter Heath is beaded over with white or flesh-coloured blooms, beautiful on their green branches. The Glory of the Snow has not yet favoured us with its exquisite colouring, but it has peeped through and is on the way, so that we shall soon see its pale blue, deep blue, blue and white, pink, or white flowers. These are all given by the varieties here. Seedling Hepaticas are beautiful, too, with their deep purple, crimson, pink, or pale blue blooms. The catalogue might be extended, though the year is but early and the season a little late. It is a tempting thing to think of and write of our favourites in such a general way, but other things are wished, and we must, perforce, obey.

The Snowdrops will soon be over, and while they are with us we may not unprofitably speak of two or three, saying a word as we go about their relative merits. If one is not mistaken it was

last year that the Aidin Snowdrop, for which we are indebted to our good friend Mr. Whittall, did not prove so fine as in the year before. This year, on the contrary, it has surpassed itself, and is even finer than at first. It has all along shown a greater tendency than most of the others to produce two flowers on one stem, and this year this feature is more than usually noticeable in the case of a clump in a low-lying place at the base of a rockery. Very fine is this Aidin Snowdrop, which botanists call *Galanthus Elwesi*, var. *unguiculatus*—a barbarous name, one can hardly help saying, and not a bit better if "Englished" into the "Claw-petalled Snowdrop," which one is led to believe is what it means. Doubtless the segments show the appearance which have led our botanists to distinguish the variety by this name, but 'tis a pity 'tis so.

Near at hand is a clump of *Galanthus ochrolepis*, said by some to be the finest of all Snowdrops. The bulbs in this clump were sent by Mr. Whittall, and have now flowered twice. One is inclined to hesitate before assenting to the opinion that it is "the finest of all Snowdrops," but should the blooms continue the improvement they show this year as compared with last one, it would be difficult to find much fault with it. The flowers in the clump are variable, but the great majority have long shapely flowers which in their early stages are exceedingly beautiful. The Cassaba Snowdrops—exceedingly handsome as they were—are, alas! nearly all away. There were no signs of the dreaded fungus about them last year, but now there is only a solitary flower left and (as usual) that not the best. Cultivate as we may the spirit of gaining pleasure from our gardens, the remorseless hand of disease plucks some of our joy from our grasp. We must then turn to the Crocus to gain from its bright flowers some cheering draught to allay our grief and console us for our disappointments.

A beautiful little Crocus seen in bloom by the writer for the first time only a day or two ago is the rather rare *C. Crewei* of Hooker, thought to be perhaps the same as *C. melanthera* of Boissier. For this I am indebted to Mr. James Allen, who received it some years ago from my kind correspondent, Mr. Whittall. This was rather an unexpected find, as the first record of this plant was from the island of Syra in 1874. Mr. George Maw tells us that it was found on the hill above the town by Mr. Elwes while on the island on his way to Asia Minor. From a corm flowered by the late Rev. Harpur Crewe in 1875 Sir J. D. Hooker figured the species in the "Botanical Magazine" (plate 6168). Mr. Maw afterwards searched unsuccessfully in Syra for it, and one of his correspondents also looked in vain for it, so that it is pleasant to know that it is in existence in Asia Minor. As Mr. Maw remarks, it is "closely allied to *C. biflorus*," and is "mainly distinguished from that species by its dark chocolate anthers." It is much smaller than *C. biflorus*, as commonly sold under the name of the "Scotch" Crocus, but not dissimilar in that respect to some *C. biflorus* received from Mr. Whittall, or to some of the others—such as *C. biflorus estriatus*. The dark chocolate anthers show well against the white inner segments with their orange throat and the orange-scarlet stigmata. The outer segments are suffused with buff, and prettily feathered with dark chocolate colour also.

A pretty little Crocus also—and one, too, which is but rare—is *C. tauri*, which I owe to Mr. Whittall's kindness. It was introduced into cultivation by that gentleman in 1892, although known previously from herbarium specimens collected by Aucher-Eloy near the Cilician Gates of the Taurus. Its shade of colour is rather distinct, and, although called "pale purple," is nearer a "pale blue" than almost any other in this garden. The segments are very pointed, and when fully open the little flower is starlike in its form. It, like *C. Crewei*, resembles *C. biflorus*, its differences "consisting in the exceptional shortness of its yellow stigmata, its self-coloured flowers, and its thinner corm tunic."—(Maw) One is tempted to say more about some of the other Crocus species or varieties now in bloom. There are some selected varieties of that very beautiful early species *C. Imperati*; some are varieties of *Imperati longifolius*, and there are also some selections of *C. Tommasinianus* which show considerable variations from the ordinary shade. I must restrain myself, however, so as to find space for reference to a pretty little Spring Meadow Saffron received last year as *Colchicum fasciculare*. The name is at present *sub judice*, as I have just sent a flower and leaf to our great English botanist, Mr. J. G. Baker. This has been done at the request of Mr. Gumbleton, who has been in correspondence with Mr. Baker regarding this *Colchicum*, but whose flowers, grown under glass, were over. It would be unbecoming of me, and would almost be "contempt of court" on my part were I to express an opinion on the question of nomenclature now referred to so eminent an authority. It is not, however, out of place to say that this is a very attractive little flower, and well worth growing. The leaves, which are rather broad, appeared about the end of the year; then two little rosy tipped and shaded buds emerged in the centre. These gradually

developed and were added to, until, before the flower was sent to Kew, there were six flowers in the cluster, which appeared from the centre of the leaves. The rosy-pink of the flowers has become fainter as the blooms have progressed; but still they are very pleasing, and have been almost "pets of the household" since their first discovery. The leaves look as if they would still extend, but at present the flowers are well above them. This little Spring Meadow Saffron has been out all winter, and is growing in rather light soil at the base of a rockery, its exposure being S.S.E.

Space fails me now, and the garden tempts one to lay down the pen for the nonce and seek pleasure among these Snowflakes, Snowdrops, Crocuses, Hepaticas, Winter Aconites, Anemones, Primroses, and other early flowers—not forgetting *Iris histrioides*, so well figured in the *Journal* of February 11th (page 111). The temptation must, however, be foregone for an hour or two, as less congenial tasks with pen and ink await one before the post goes. Still, one can steal a glance through the window and see some, at least, of one's favourites. With these and the Hyacinths and Narcissi in the window even irksome things are lightened, and our hearts uplifted by the beauty of the flowers.—S. ARNOTT.

CURE OF CHLOROSIS (OR YELLOWS) IN PEACHES.

A FEW remarks on this subject from one who had the disease for several years in its worst form on several trees under his charge may be of interest at this season. These were all grown under glass, and are now, without exception, as healthy as any trees in the country.

I am encouraged to state my failures owing to a letter received from an unknown reader of the *Journal of Horticulture* whilst the experiments were being carried out, which was an acknowledgment of the help he had received from some notes of mine on another subject in these pages. The writer said, "I think if more of us would only confess a few of our perplexities and failures a little oftener, and send them up to 'the dear old Journal,' all the horticultural world would be great gainers. For thirty-five years have I been working and trying, but I am still willing to confess that I am often perplexed."

In the first place, I may state that the soil here is cold and heavy, and is on the magnesian limestone formation. Some may be tempted to remark that it is just the soil for fruit trees. So it is for certain kinds, Apricots and Plums doing remarkably well, Apples and Pears indifferently. The foliage always has a yellow, unhealthy appearance, the former on the Crab stock cankered badly, though young trees on the Paradise stock planted in recent years are more promising.

Vines under glass, the majority of which are forty years old, invariably carry heavy crops of well finished fruit. The borders, however, have been renewed of late years.

Peaches not being a success on the open walls in this north-eastern county, a house was built 50 yards in length for the express purpose of growing them. The border was well drained in the usual manner, fresh turf, with the grass side downwards, being placed over the drainage. The best of the old soil was retained, but quite three parts of the border was composed of turf cut from an old pasture, which had been stacked a few months previously. Manure was not used, but wood ashes and charcoal were freely incorporated with the soil.

In due course the trees were planted and grew rapidly the first season, the foliage being exceptionally healthy. The house was not heated at that time, so the trees started naturally the following spring. They grew freely, but by midsummer several of the trees showed undoubted symptoms of the yellows. The first to become affected was a tree of Goshawk, followed by Royal George and two or three others. By autumn the foliage on the affected trees was yellow and sickly looking, though they had made good growth. These trees were afterwards lifted, similar soil to what was first used being given to them. For a few months there was an improvement, but eventually all the trees (upwards of three dozen) became affected. Stirling Castle suffered the least, owing probably to this variety being always worked on the Brompton stock.

I suggested to my employer that the soil should be analysed. He thought that was unnecessary, as we obtained good Peaches. But after the trees had been affected for two or three years the growths became weaker, many of the shoots dying, and eventually some of the worst trees were destroyed. In the meantime many experiments with chemicals were tried. Having read of Professor Sachs's experiments with sulphate of iron at Giesmbeim, I came to the conclusion that it was iron of which the soil was short. I therefore dissolved sulphate of iron in warm water and applied it to the trees. In some instances the roots were bared before the

trees started into growth. In others the soil was pointed up, and the mixture well washed in; all the trees had at least 1 lb. each, which was repeated during the season. Some trees received 7 lbs. of sulphate of iron during the season without the addition of any other chemical. Others, again, had nitrate of soda and bonemeal, sulphate of ammonia, and superphosphate, kainit, soot, and lime.

After trying these experiments for two years there was no improvement to be observed. The trees still carried fair crops of fruit of medium size, but the leaves were yellow, although a quantity of soil had been burnt the previous year and well incorporated with that in the border. I consulted several of my friends but could get no farther advanced, sulphate of iron being the receipt invariably given to bring back the colour to the leaves.

As a last resource I found some soil on another part of the estate, quite different in composition from that previously used, being of a sandy nature. This I used in proportion of two to one of the other, plenty of broken bricks with the dust taken out being the only ingredient mixed with it. The first season I experimented with three trees of different varieties; after removing the old soil the roots were well shortened back and the new soil made very firm.

The change was marvellous. Although the young growths came yellow as before they gradually improved in colour, and before autumn the trees that had received the new soil had made splendid growths and were the picture of good health, in marked contrast to the others. The whole of the trees in the house were afterwards treated in the same manner with a similar result, and I very much doubt if there can now be found a more healthy stock of trees in the country.

The above shows that from failures we may often learn a lesson. It also proves that one cannot always replace artificially what is required in the soil.—S., Yorks.

IRIS BAKERIANA.

MANY times have graceful lines been written in the pages of the *Journal of Horticulture* by Mr. S. Arnott anent the beauty of many of the early Irises, such as *reticulata*, *histris*, *histrisoides*, and others, with *I. Bakeriana*, of which the woodcut (fig. 38) is a representation. Of charming beauty and delicious fragrance this Iris thoroughly deserved the first-class certificate accorded to it by the Floral Committee of the Royal Horticultural Society at a meeting held on February 11th. The exhibitors were Messrs. R. Wallace & Co., Colchester, who have placed prominently before the horticultural world many gems of chaste beauty. The colour is rich, deep, royal blue, the slightly paler coloured falls being faintly spotted with white.

PRECEPT AND PRACTICE.

(Continued from page 132.)

"THE common round, the daily task," cannot, so far as our work is concerned, drift into a monotone, and if ever this is felt to be the case the fault is in the worker, and not in the work. The necessity of forethought, continually enforced in all horticultural teaching, which I will here call work by anticipation, is too predominating a factor in the sum of even one day's work to admit of mechanical motion. Work by anticipation opens or shuts the dampers, the ventilators, stirs up or slacks down the fires, shades or admits light, saves the plants from flagging, Onions from the maggot, early Potatoes from the frost, and in fact does a hundred things, and does them at the right time. These hundred little things are to an unobservant man so many little rocks which he will bump against in a day to the detriment of his craft. To be expert in many things, as well as to avoid trouble (not work), our young gardener cannot be too young to commence this prescient training, which if followed up may also carry him far enough to interpret and press into service some simple natural phenomena which otherwise he might set aside as being beyond his ken.

"Come up here, boy, and open your eyes," and I went up from the stokehole, where I was vigorously engaged at firing up in the cool grey of an early summer's morning, to be awakened to the fact that by the time the pipes would be hot the sun would be upon that particular range sufficiently strong to accomplish the object without their aid. "Now, my boy, don't you see that you are wasting fuel and time? small matters compared to the heat you are sending into the houses to let out immediately through the ventilators, drying up everything in the bargain." "Yes, sir, I see." "Well, my boy, always try to see these things beforehand." Now it is astonishing how much there is to see in looking ahead, and how much work there is to be done by anticipation; so much so, indeed, that one is inclined to say the smart man does nearly

everything beforehand. One Chrysanthemum grower I knew dressed the bulk of his exhibition blooms beforehand as they developed on the plants, and when the critical hour was at hand there was no hurry, no confusion, and no trusting of the delicate work to the tender mercy of inexperienced hands. Surely forethought is the highest exposition of "heaven's first law."

Having alluded to simple natural phenomena, we may here touch upon a topic of daily anxiety—the weather. "It is absurd," you will say, "to bring that into our calculation." I beg to differ. We cannot afford to leave it out; we must have it, I admit—take it as it comes, but there are different ways of taking it, the best possibly being by the forelock as little as there is, unfortunately, to grasp; but that little is often of great use. Young people are not, as a rule, I find, as well acquainted with the working of our two most prominent meteorological instruments as they should be, and a little analytical discussion may dispel some error surrounding at least one of them. First by right of pre-eminence (to us) comes that simple instrument the thermometer, a compound word

FIG. 38.—IRIS BAKERIANA.

—thermo-meter—springing from two Greek roots, *Thermo*, heat; *meter*, a measure; literally heat measurer. Simple as it is, without accurate observation misleading statements occasionally occur which are worse than useless.

There are, I fear, few of our boys at starting who read a thermometer correctly, and we know for a fact that many persist in misconstruing its common-sense name into "theometer." As regards observation one I knew, and a big boy too, who daily watched an instrument for over a month from which the bulb had been broken off, and duly recorded the dislocated data in his diary. Two observers should agree in their observation, which, if they are young ones, I seldom find them doing. One will look up, the other down, with a variation of several degrees, especially if the instrument is on a small scale. When I note a lad reading the thermometer I like to test his capability of doing so correctly, and point out to him that in order to do so it is necessary to bring the eye on a level with the height of the mercury in whatever position the instrument is placed. One lesson is sufficient to set the matter right for all time—his time, and the value of all such observation is entirely dependent upon its accuracy. Due justice is not always given by placing even the most reliable instrument in a suitable position beyond the contingent influences of conductors, so desirable in the case of correct shade temperature readings,

whilst affording facility for free communication with the atmosphere. This being the most important record of temperature (shade readings), we have to make it appear to be incumbent upon those who make public statements of it to use a standard instrument, or at least one of proved reliability.

The barometer, also from the Greek, signifying in our tongue a measure of weight—Baro-meter, is worthy I think of an attempt to clear away some apparently mystical and undoubtedly erroneous ideas some persistently regard it with. It is simply what its name implies—viz., a measure of weight—the weight or the density of the atmosphere. Its sole value as a weather guide is founded upon those calculations we are able to deduce from atmospheric variation. Commonly called a weatherglass, because it has so little claim to the appellation I suppose, and not any where the deservedly popular aneroid is concerned, for the glass is there replaced by a metal box; it claims no prophetic power beyond that pointed out. The custom of marking off the different heights, stormy, rain, fair, set fair, appears to me as relevant as it would be to mark at certain hours on the clock, breakfast, dinner, tea, and supper, and then if not forthcoming to say that the clock is wrong.

Anyway my little aneroid will never deceive anyone in that respect, for years ago I removed from its face those too often sources of error and mystery. It tells me now so many inches, it can tell no one any more with certainty, but we can hardly overestimate its value. One must allow that so far as the general public are concerned, or that portion of it to whom its significance is represented by the mackintosh or umbrella, the definitions are well enough so far as they go, but they do not go far enough for toilers of the land, or of the deep, who are more seriously interested in the shadows of coming events not to include all the available data that close observation may afford. We may take it for granted that all storms of abnormal severity upon record have been preceded by a rapidly falling barometer, and that in some instances it is the only indicator we have of an approaching change. As an instance of this I may relate the most remarkable and sudden change which came under my notice during a winter of Arctic severity. It was the sharpest night of a series of sharp nights, when the thermometer fell below zero, and our anxiety to keep things right had risen in proportion. In the wee sma' hours I made a final round with the man "on duty." "No sign of a change?" No, but "the glass" was falling—falling rapidly; that was about 2 A.M., and at seven I awoke to the sound of pattering rain, with a blessed change of about 40° rise in the temperature.

Some years after that occurrence, during an autumn season when Chrysanthemum growers' anxieties approach a climax, under similar indications of a change, all preparations were made for a battle with the breeze. The barometer fell to an alarming extent, but so far as other appearances were in evidence there was nothing to foretell the coming storm. The day dragged out still and oppressive. Bulky, light coloured clouds moved by an upper current of air revolved round the district all day, and so persistently they followed a circular track that it was a remarkable phenomena. I concluded, rightly or wrongly, that we were the actual centre of a widespread cyclonic disturbance, for next day's press reports detailed the damage which took place all around us at the time we enjoyed immunity from it, although later on at night it blew great guns, and shattered the conceit out of one old workman who had been laughing at the "gaffer's" belief in that "weatherglass," and all the fuss of preparations made. I should like for every bothy to have one of those portable, cheap, interesting, and useful little instruments—an aneroid barometer—that our lads might early learn what it is, what it can do, and what it cannot do, more of which I should like to detail, but it must no longer detain.

I suppose it is that a gardener, through life being anxious and troubled about many things from which the weather can never be detached, becomes addicted through daily and almost hourly observations to a continuous forecasting within the limits of twelve or twenty-four hours, and that with more or less success. Truly we cannot do much in this respect; but it is observation that prompts us to grasp opportunities which may otherwise be overlooked, and if there are "more things in heaven and earth than are dreamt of in our philosophy," we may, at least, endeavour to unravel that apparently hopeless tangle the weather by such means as are presented to us, and possibly find them means to the end. The science of meteorology scarcely appears to have given results commensurate with the labours expended on it, but much has been done to clear the way by removing various superstitious theories so long an obstruction. "A hopeless task," some may say. "There are no fixed rules or laws to guide our judgment." To such I would reply, "All Nature is but art unknown to thee; all chance, direction which thou canst not see."—AN OLD BOY.

(To be continued.)

ANTHURIUMS.

IN these days when flowers and flowering plants are the rage and have to be produced in such enormous numbers, useless material must be discarded altogether. The foliage plants which many of us prided ourselves in growing at one time are destined to disappear from gardens generally if the present rage continue.

But I look forward to the more extended culture of the best forms of *A. Andreanum* and *A. Scherzerianum*. For years their claims have been strongly advocated, and it is regrettable that they are not more generally grown at the present time. The last variety is far superior to *Masdevallias*, although we have no objection to these plants, and after *Poinsettias* are over we appear to want scarlet in our gardens for decorative purposes. Certainly there are Tulips and scarlet "Geraniums," but the first are not suitable for the purposes to which these Anthuriums can be employed, while the "Geraniums" are common by their side. Personally I cannot admire the salmon, spotted, and white forms. *A. Andreanum* produces its spathes more or less the whole of the winter and spring, and they last a very long time in a cut state. In a large vase what can be more effective than three or four of these, associated with the same number of *Callas* and a few leaves of the latter. The arrangement, though simple, is striking. Plants the spathes or flowers of which last a long time, are what we need at the present time.

A. Andreanum requires stove treatment, and a number of plants, if the spathes are not needed for cutting, are striking objects for the embellishment of the house in which they are grown. *A. Scherzerianum* certainly requires stove treatment while growing, then can be rested in an intermediate temperature, and is all the better for this treatment, as the plants flower more profusely and grow with greater vigour afterwards. One advantage of resting them in a lower temperature is that they are easily forced into bloom afterwards by introducing them into strong heat. Even supposing these flowers are not needed in a cut state, they are charming associated with *Cattleyas*, *Coelogynes*, *Cypripediums*, *Odontoglossums*, and plants of this nature. Both spathes and foliage correspond admirably.

These plants are slow of propagation, which may be one cause against their more extended culture. But in spite of this they are worth growing with the object of forming a good stock in course of time. The best plan is to grow *A. Scherzerianum* until it divides its crowns freely, and they are large enough for taking off, when the plants may be split up and established in 5 to 7-inch pots according to their size. The same remarks apply equally to *A. Andreanum*. Some of the compact growing kinds soon produce three or four crowns, when they can be rooted separately, the remaining stem above the pot being cut into lengths of two joints. These if plunged into strong bottom heat soon make plants. The old stool frequently starts a number of growths from the base, which in course of time can be taken off and rooted separately.

Anthuriums are not very particular about soil, provided it is light, open, sweet, and porous. We find they will grow with the pots nearly full of crocks, and then filled up with moss used in cakes as frequently found in woods. They will grow in peat, also in fibrous loam. Our compost is good fibrous loam and peat in equal proportions, with broken bricks freely added, and a good layer of moss on the surface. The moss is replaced annually, and the soil is washed from the roots every second year. While in a lower temperature the plants are kept fairly dry at their roots, or else we find their fleshy roots perish.—W. BARDNEY.

LOOKING ROUND.

ALTHOUGH only an amateur I eagerly peruse the pages of the *Journal of Horticulture* as it is issued week by week, and on reading the article "Looking Round" I thought I should like to say that although only an amateur I have spent many days of my holidays at different times in visiting some of the county seats and nurseries within some miles of where I live. Permission of the head gardener or the person in charge has been asked to look round, and I have been shown through and treated more as a fellow gardener and not as an intruder in their domain because I was only an amateur.

In several cases where gardeners have to depend upon themselves for the keeping up of their stock I have been able to exchange a few cuttings or plants, proving I hope beneficial to both parties. One pleasant recollection I have in my mind is of a day when in the neighbourhood of Highbury, and being greatly interested in the culture of Orchids I made my way to the lodge entrance of the residence of the Rt. Hon. Jos. Chamberlain, and asked (not without some hesitation) to see Mr. Burberry, and the pleasant way I was received by that gentleman and shown through the various Orchid houses I shall not easily forget. I take this opportunity of thanking all gardeners who are willing to help such as I, who are lovers and growers of the flowers in our own quiet way but not professional gardeners.—AN AMATEUR.

WEATHER IN LONDON.—Though the end of last week was fine on the whole this one has commenced with the proverbial March winds in very strong force. Monday morning was bright, as was Tuesday until between two and three o'clock, after which rain fell in drenching showers on both days. A gale of wind made it still more uncomfortable. Early on Tuesday morning there was a little frost. On Wednesday the same conditions prevailed; rain and snow were falling rather freely at the time of going to press.

WEATHER IN THE NORTH.—February closed with a good deal of rain, occasional sleety showers, and boisterous cold westerly winds, with touches of frost on some mornings. Monday was cold, but fair in the afternoon and evening. On Tuesday morning the hills and the lower grounds were whitened, and 5° frost were recorded during the night.—B. D., *S. Perthshire*.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meetings of the Society will be held on Tuesday, March 9th, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. At three o'clock Prof. W. M. Ward, F.R.S., will deliver a lecture on "Microscopic Gardening."

WOLVERHAMPTON SHOW.—The Wolverhampton Floral Fête, which has made such great progress during recent years, we find by the schedule is to be held this year on July 13th, 14th, and 15th in the West Park. Excellent prizes are provided in classes for specimen plants (£45), groups (£50), also for Orchids, Roses, Pansies, and Violas, Carnations and Pinks, fruit and vegetables. The "Hawley" silver challenge cup, value £20, is offered for a "Display of Plants or Floral Arrangements." A large and diversified exhibition may be expected.

WOODBIDGE HORTICULTURAL SOCIETY.—The annual exhibitions held in the Abbey grounds of the above pleasant Suffolk town rank as the best in East Anglia, and the next show may be expected to at least equal its many predecessors. The schedule is of wide scope, comprising 176 classes. Roses and floral decorations are prominent features. A 25-guinea challenge cup is provided for twenty-four Roses, and a 12-guinea cup for twenty-four Teas and Noisettes. Silver medals are also provided by the N.R.S., Mr. O. G. Orpen, and Rev. J. H. Pemberton.

THE SHREWSBURY SHOW.—Famous as previous exhibitions have been at Shrewsbury, the show, which opens in the Quarry Grounds on August 18th, should eclipse them all. In the schedule to hand we find the following special awards:—The Royal Horticultural Society offer a gold Banksian medal for the exhibit (not for competition) which in the opinion of the Council of the R.H.S. best represents the progress of horticulture for the last sixty years. The R.H.S. will also give a silver-gilt Knightian medal in the Victorian decorative fruit class, with other medals and awards as the Council may decide. The Worshipful Company of Fruiterers (London) will give the gold medal of the Company to the Victorian decorative fruit class, and three silver medals of the Company, as specified in the schedule. The Veitch Memorial Trustees offer the Veitch Memorial medal and £5, in addition to the first prize of the Society for decorative dessert table. The Committee of the Shropshire Horticultural Society offer three special Victorian awards, consisting of handsome full dessert services of the value of £12 12s. each, manufactured at the far-famed Coalport, Salop, china works specially for this show, with royal monogram in the centre, and of which no duplicates will be issued—1, For the most attractive display of rare plants (not for competition), grown by the exhibitor; 2, For the most attractive display of cut flowers, in space not exceeding 25 feet by 6 feet (not for competition), grown by the exhibitor. 3, For the most novel exhibit specially illustrating the progress of horticulture during the last sixty years, either in plants, flowers, fruit, or vegetables (not for competition), grown by the exhibitor. The Society will also award gold and silver medals on the recommendation of the Judges and approved by the Committee. Valuable money prizes are also added, nearly £340 being offered in six classes, the total for the show exceeding £800.

— OXFORD SHOWS.—We are informed that a Commemoration Show will be held at Oxford on June 29th, and a second Summer Show on August 24th.

— UNITED HORTICULTURAL BENEVOLENT PROVIDENT SOCIETY.—The annual meeting will take place on Monday evening next, March 8th, at the Caledonian Hotel, Adelphi. The chair will be taken at eight o'clock by Mr. A. Dean.

— DEATH OF MR. WILLIAM MILNE.—We learn that this well-known gardener, whose afflictions entitled him to be placed on the pension list of the Gardeners' Royal Benevolent Institution at the recent election, died on Monday morning last. He was only forty-three years of age. He leaves four children, under thirteen years of age, dependent on the widow's earnings in a small lodging house. This seems a fitting case for the benefit of the Royal Gardeners' Orphan Fund.

— ROYAL GARDENERS' ORPHAN FUND.—A meeting of the Committee was held on February 26th, when William Marshall, Esq., was again elected Chairman of the Executive. Amongst others the following special receipts were announced:—Chislehurst Gardeners' Mutual Improvement Society's concert, £23 12s. 6d., a special vote of thanks being accorded; Messrs. Bunyard & Co., nurseries, Maidstone, £5 5s.; Mr. Owen Thomas, Frogmore, £2 2s.; Mr. T. Whillans, Blenheim, £2; Isle of Wight Horticultural Association, result of a lecture by Mr. H. J. Jones, £1 2s.; Miss Noble, Henley, £1; Mr. J. Kipling, 11s. 7d., and several smaller sums. The result of the election was announced, whereby thirteen children are placed on the Fund and the respective guardians appointed, the mothers in each case undertaking the duties.

— PRESENTATION TO MR. DAVID THOMSON.—Since learning of Mr. Thomson's intention of retiring from Drumlanrig, many of his old pupils think it a fitting occasion for showing their esteem and appreciation of his many good qualities as a man and his abilities as a gardener, also their gratitude for his kind interest in their welfare, propose making some suitable presentation, as may be afterwards decided upon. In case some of Mr. Thomson's old pupils may not have received a circular, we are requested to notify that subscriptions will be duly acknowledged by Messrs. J. McKenzie, Linton Park, Maidstone; W. Allan, Gunton Park, Norwich; J. Young, Zoological Gardens, Regent's Park; J. Melville, The Lodge, Finsbury Park, N.; T. S. Simpson, Stourton Court, Stourbridge; A. Henderson, Thoresby, Ollerton, Newark; J. Garrett, Whittinghame, Prestonkirk, East Lothian; J. Henderson, Balbirnie, Markinch, Fife; W. Priest, Eglinton Castle, Irvine, Ayrshire; and W. B. Fisher, Stackpole Court, Pembroke. This considerate action of the "old pupils" is very gratifying, and cannot fail to be appreciated by their worthy old chieftain. We have pleasure in making the project widely known.

— READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The fortnightly meeting of this Society was held in the club room on Monday evening, when Mr. T. Neve presided over a very large attendance of members. After the usual business had been disposed of, Mr. P. H. Foulkes, B.Sc., Edinburgh, of the staff of the University Extension College, Reading, gave an interesting and practical lecture on "Insects Injurious to Plant Life." Mr. Foulkes, in opening his subject, dealt with the great damage done annually by the various pests, and drew attention to the fact that the annual loss to the country runs into thousands of pounds sterling. In instancing some of the most noticeable pests he quoted the Hop aphid as doing damage in one year to the extent of £500,000. The lecturer touched upon the resemblance of fungoid growths to the results of insect attack, and showed this more clearly by throwing on the screen photographs of Swedes which had been attacked by "finger and toe" and Swedes which had been attacked by the "Turnip gall weevil." An account of the life history and habits of the winter moth was given, and, knowing these features, the gardener is in possession of valuable facts which he could make use of to overcome the pest. The eelworm was also taken as a type of garden pest. Pictures were put upon the screen showing the attack on Cucumber and Tomato roots, as well as the various life stages of this pest. In dealing with the measures of prevention and remedy he instanced, among others, the use of capture plants as a means of clearing the ground of the eelworm, a practice which has been adopted in Germany on a large scale with considerable success. In concluding, the lecturer said that though we knew the habits and characteristics of a number of our pests, yet there was a great deal of information still to be learned, and he pleaded for the help of those who, by their natural habits and calling, were continually coming into contact with insect pests. A number of questions were asked, and an interesting discussion followed.

— GARDENING APPOINTMENTS.—Mr. R. Scott, late of Steep Hill Castle, Isle of Wight, has been appointed to succeed Mr. T. H. Crasp as head gardener to the Right Hon. F. J. S. Folijambe, Osberton Hall, Worksop, Notts. Mr. Frederick Cockell, for the past four years foreman in the gardens at Sand Hutton, York, has been appointed gardener to Mrs. Fleming, Normanby Hall, Middlesbro'-on-Tees. Mr. Herbert May, formerly head gardener at Markree Castle, Collooney, Sligo, has been appointed head gardener to G. Gatehouse, E. q., Westwood Noctorum, Oxtou, Birkenhead.

— ELECTRIC TREES IN DAKOTA.—On January 4th, during the worst of the great wind and snowstorm at Huron, the air was heavily laden with electricity. The Cottonwood trees in front of the Chicago and North-western offices presented a very strange and novel appearance. The trees were buried in snow almost to their tops, but at the end of each twig on every branch in sight was an electrical spark about as large as a common field Pea. On taking hold of a twig the spark extinguished, but on withdrawing the hand the spark reappeared. Dispatcher Wilson, who wore a glove with a hole in the thumb, took hold of a twig, and the spark transferred itself to his thumb and back to the twig when he let go. There was no shock experienced, says an American contemporary, in handling the twigs, and the light did not waver or tremble, but was quite steady. The trees looked as if a colony of fireflies had settled upon them for the purpose of an illumination.

— THE MIDLAND CARNATION AND PICOTEE SOCIETY.—We have received the annual report of this Society for 1896, and schedule of prizes for 1897. It is a remarkably complete production, indicative of life and prosperity. The exhibition for 1897 will be held at the Botanical Gardens, Edgbaston, Birmingham, on Thursday and Friday, August 5th and 6th; or should unforeseen circumstances necessitate any alteration in the date, notice will be sent to all subscribers not later than July 15th. Open to the public on the first day at 2 P.M., and close at 8 P.M.; on the second day at 10 A.M., and close at 6 P.M. Honorary exhibits of other flowers will be accepted from subscribers to the Society, and the Society's silver-gilt medal will be awarded to the most meritorious honorary exhibit in the exhibition, the Society's silver medal to the three next best honorary exhibits if of superior excellence, and the Society's bronze medal will be awarded to any other exhibits recommended by the judges, after the style of the Royal Horticultural Society in London. Any further information can be obtained from Mr. Robert Sydenham, Mr. H. Smith, or any member of the Committee. Total value of prizes, challenge cups, medals, &c., about £160.

— CIDER AND FOOD APPLES.—In an interesting lecture delivered before the Society of Arts on Wednesday evening this week, Mr. George Gordon remarked—"From the Apple orchards the hundreds of inferior varieties, whether belonging to the table, cooking, or cider sections, should be swept away and replaced with others that are sure bearers and produce fruit of good appearance and high quality. I would advise also that the area of many cider orchards, which in the western counties form, it is computed, about four-fifths of the whole, be reduced by grafting the trees with dessert or cooking varieties. Cider is an excellent beverage when properly made, but we are now concerned with making the orchards as profitable as possible, and it is obvious that Apples worth from £10 to £20 per ton are more profitable to grow than those which will not realise more than from £1 to £5 per ton. It is also evident that to obtain a full return from their orchards farmers must grow both late and early varieties, and adopt some inexpensive method of storing the fruit of the former until after the early supplies have become exhausted. The most profitable of the cooking varieties are Bismarck, Ecklinville, Dumelow's Seedling, Gascoyne's Scarlet, Golden Spire, Lane's Prince Albert, Lord Suffield, Newton Wonder, Potts' Seedling, Tower of Glamis, and Warner's King. Then of the dessert varieties I would recommend Blenheim Pippin, which is slow in coming into bearing when planted as an orchard standard, but grafted on large trees it quickly becomes productive, and the fruit, by reason of its handsome appearance and high quality, invariably commands a good price; Cox's Orange Pippin is one of the most profitable of dessert Apples in districts favourable to it, and when the fruit is properly marketed; Duchess of Oldenburg, an early variety which has a short season; Devonshire Quarrenden, useful for planting within a short distance of the market; King of the Pippins, and Worcester Pearmain. These form but a small proportion of the Apples in the catalogues, but before we can make our orchards profitable we must follow the example of the American growers, and instead of planting two or three trees each of a hundred varieties we must plant a hundred trees each of a few varieties, and these of the very best."

— FEBRUARY WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected), 39.27°. Wet bulb, 38.32°. Mean maximum, 45.48°; mean minimum, 35.12°. Highest, 56.4° on the 22nd; lowest, 24.8° on the 1st. Mean of maxima and minima, 40.30°. Mean radiation temperature on grass, 29.76°. Lowest, 12.8°, on the 1st. Rainfall, 2.565 inches. Number of rainy days, fourteen. Greatest amount on one day, 0.88 inch on the 5th.—W. E. LOVELL, *Observer, York Road, Driffield.*

— KOELREUTERIA PANICULATA.—This beautiful Japanese tree is not nearly as much appreciated in ornamental gardening as it deserves to be. Nurserymen generally say that the orders for it are comparatively limited. It is, says "Meehan's Monthly" one of the most beautiful of our small trees, having striking characteristics at all seasons. When in the springtime of its growth few Fern fronds are prettier than the leaves of this tree, while at midsummer it is a complete mass of golden beauty, while in the fall of the year its rich crimson foliage vies with many American trees that have been celebrated in this respect. Even in the winter time the characteristic growth of the branches is particularly striking. The whole head of the tree, in fact, presents beautiful outlines that would be admired by any lover of artistic rules.

— CUTTING DOWN TREES ON COMMONS.—The adjourned summons against Lady Saunders, the wife of Sir Edwin Saunders, residing at Fairlawn, Putney Common, for aiding and abetting her gardener, Abraham Newell, in wilfully damaging a Birch tree growing on Putney Heath came on for hearing, together with the summons against the gardener himself for his participation in the matter. The tree was cut down on Christmas Day, as her ladyship found that it obstructed the view of the common from her house. The Magistrate now received an intimation that Sir Edwin Saunders had paid £5 5s. to the fund for the maintenance of the common, as was suggested when the case was first before the Court, but the Conservators were not satisfied with the undertaking given. Sir Edwin wrote that he would take care that no one engaged at his house should re-open the subject. Mr. Francis thought Sir Edwin should undertake that there would be no repetition of such conduct. As to the gardener, he had simply acted over-zealously, and in the interests of his employer. Mr. George Bell, who represented the gardener, said although he had pleaded guilty he was not the man who actually cut down the tree. Mr. Birkett, for the Conservators, pressed for an adjournment to give Sir Edwin an opportunity of carrying out the undertaking. Mr. Francis, while sanctioning this course, said he would look upon any repetition as a serious offence, and should not deal with it with the same leniency.—("Garden.")

— THE HEIGHT OF THE REDWOODS.—It has usually been considered by the students of American trees that the Sierra Sequoia was the tallest, as it is the largest, tree in North America. Professor C. Sargent, writing of the Redwoods in "Garden and Forest," states that "three individuals, each 325 feet high, have been measured in the Calaberas Grove; and these, so far as I have been able to learn, are the tallest American trees whose heights have been authoritatively recorded. On the 7th of September, 1896, however, General Henry L. Abbot, Mr. John Muir, and I were on Eel River, near the lumber-camp at Scotia, California, and measured a Redwood which had lately been felled, and which led us to suppose that this species grows to a much greater height than any other American tree. This particular individual was only 662 years old, with a trunk diameter of 10 feet 5 inches at 6 feet above the ground, and of 9 feet 15 inches above the ground; it measured 230 feet to the first limb, where the trunk was 2 feet 9 inches in diameter, and 340 feet to the top of the stem. In trunk diameter it was smaller than the average size of the trees in this particular forest, which extends without a break for about twenty miles along both banks of the Eel River; its height was not exceptional, and may be taken as the average height of the trees in this forest; and the men in this camp who pass their lives in working among these trees were confident that individuals 100 feet taller than the tree we measured could be found. This, perhaps, is not improbable, as Redwood trunks from 15 to 20 feet in diameter are not rare, and occasional trees with trunks from 22 to 25 feet in diameter can be found. Judging by the fact that the Eel River trees, which had grown in a deep alluvial deposit, had only attained a diameter of 10 feet 5 inches in 662 years, some large Redwoods must have lived through several centuries and reached a much greater height. Of other trees measured in this forest one was 43 feet in circumference at 5 feet above the ground; another was 45 feet in circumference at the same height, and another 52 feet 5 inches. The trunk of another measured 4 feet 3 inches in diameter 180 feet above the ground."

— THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.

—A meeting of the above Society was held in the Parish Schoolroom on Tuesday, February 23rd, when a paper was read by Mr. W. P. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft, on "The Routine Cropping of the Kitchen Garden." Taking each vegetable alphabetically, the essayist explained the mode of cultivation adopted successfully by himself, the nature of the soil, and the varieties with which he had attained that success. Early, midseason, and late crops each received their share of attention throughout the entire season of growth. Time would not allow all the details of the subject to be discussed; but the essayist drew attention to the many difficulties to be contended with in the kitchen garden. Changes of weather and insect pests often cause a great deal of annoyance and anxiety; against these it is well to be prepared, by which means ultimate success will in most cases be rendered sure and certain.—F. L. T.

— RHODODENDRON PRÆCOX.—The race of dwarf early flowering Rhododendrons which originated from the crossing of *R. ciliatum* with other species and varieties claims as one of its prettiest members the variety under notice. In this particular instance *R. ciliatum* was crossed with *R. dauricum*. *R. præcox* cannot be said to resemble either of its parents very closely. Whilst it has the bushy habit of *R. ciliatum* with its larger flowers it has the smaller leaves of *R. dauricum*, the colour of the flowers being rose. Although perfectly hardy a sheltered position should be found for this variety, as from its early date of flowering (latter end of February) the blooms are sometimes damaged by frost if grown in an exposed position. In addition to being a good plant for outside work its exceptionally free-flowering qualities make it a delightful plant for lifting and flowering in a cool greenhouse. Plants can be grown 3 feet high and 3 feet in diameter, and be so thickly covered with bloom that the leaves are scarcely visible.—W. D.

— ELECTRICITY AND SEED GERMINATION.—Some experiments recently made at the Massachusetts Agricultural College by Mr. Asa S. Kinney seem to show that a current of electricity will accelerate the germination of seeds. In a collection of seeds treated for twenty-four hours, 30 per cent. more germinated under the current than in lots untreated, and the seeds which received the electrical stimulus gave a higher percentage of germination than others. In many cases electricity seems to act a good deal like light does in its stimulating effect. It must be understood, however, that even if we admit this we do not know the best methods of using electricity upon plants in the soil, nor what strength of the current will probably secure the greatest growth. The range and the strength of the current which accelerates germination is found to be exceedingly limited. So far as these experiments go to form a basis of judgment it would appear that the strength of the current which shows the greatest growth of radicles is equal to about three volts, where an interrupted induced current is used.—("Garden and Forest.")

— "MIMICRY IN NATURE."—Such was the title of an able paper read by Mr. Bott of Walton at a recent meeting of the Wakefield Paxton Society in presence of a good and appreciative gathering, over which Mr. Brown of Outwood presided, with Lieut. Goodyear in the vice-chair. The essayist, who is an old friend of the Society, said in his introductory remarks that copying or imitating was universal throughout animated Nature, and a strong bond of sympathy united lovers of Nature and the objects of their regard. It was only in the exercise of this spirit of sympathy that men could enjoy Nature. The wonderful power of adaptation to circumstances in natural objects was one strong link which bound them so closely to thoughtful men. The speaker, proceeding, asked his audience to consider his subject under (1) Co-operation or Division of Labour—in the floral world—illustration, the Corn Blue-bottle; (2) Parasitism, the Yellow Rattle (as illustration—a thief and a robber, a sponger who would rather die than work—the Clover Dodder and the Mistletoe); (3) Mechanical Action, adopted by many plants to secure cross fertilisation, and by others to convey the seed to a distance; (4) Clinging (in plants), as the Virginia Creeper and others; (5) Climbing, as in the wild Rose; (6) Necessitous Cases, as in plants, or branches of the same plant or tree, which raised themselves by twining around a stronger neighbour; (7) Forethought, some trees and plants laying up such stores of life as to send out new shoots long after they were cut down; and (8) Decoy Plants, such as assumed various forms in order to induce bees to visit them with the pollen. Under these heads Mr. Bott supplied much information which was more than ordinarily interesting, and at the same time, to use his own phrase, afforded "a fascinating side view of plant life." On the proposition of Mr. Webster seconded by Mr. Geo. Parkin, cordial thanks were given to the essayist.

— BOTANICAL RESEARCH.—The American scheme for a laboratory for botanical research in the Tropics appears to be assuming a definite shape, Prof. MacDougal having undertaken the duty of organising the Commission which shall visit various localities for the purpose of selecting a site. In a letter in the *Botanical Gazette* for January, Prof. Humphreys of the John Hopkins University advocates the claims of Jamaica, where there are already two botanic gardens, at Castleton and Gordon Town, and where the Governor, Sir Henry Blake, is interested in biological science.

— ONIONS.—Our consumption of Onions and also our importations of Onions continue to increase year by year. The average quantity annually brought into the United Kingdom for the three years 1894 to 1896 was 5,702,928 bushels, valued at £714,449. We thus pay to foreign growers, says a contemporary, nearly three-quarters of a million sterling per annum for a product which, though widely cultivated in this country, has not a sufficient area allotted to it. In America the crop is regarded as so important that a farmers' bulletin has been issued from Washington urging the necessity of the extended and improved cultivation of this nutritious bulb. Light, well-drained fertile soils are recommended, especially such as are rich in organic matters. Liberal dressings of fertilisers are advocated, applications of 200 lbs. to 400 lbs. of nitrate of soda in four equal dressings, 800 lbs. to 1000 lbs. of kainit, and a few hundred pounds of bonemeal per acre being suggested. The varieties of Onions that are most successfully cultivated in the United States include the Danvers, Extra Early Red, Egyptian, Red Globe, Yellow Globe, Potato Onion, Shallots, Silverskin, Wethersfield, White Globe, and Yellow Strasburg. Of introduced varieties preference is given to the Prizetaker. The method of cultivation recommended is to start the seed under glass, and afterwards transplant into the open field. For storing the bulbs after harvesting, dry cool rooms are considered to afford the best results. The growing of Onions for seed, such as is practised by English cultivators in Bedfordshire, Kent, and elsewhere, is a separate business. Among the pests of the crop are the maggot of the Onion fly (*Phorbia ceparum*) and the fungus called Onion smut (*Urocystis cepulae*); methods of combating these are well known to English growers.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES' AWARDS.

SURELY the comparison instituted by your correspondent, Mr. Alexander Dean (page 162) is neither fair nor logical. Any comparison between the awards made respectively by the R.H.S. Committees and by the deputations appointed by the Council at the York and Chester Shows, based upon the suggestion of an arithmetical average per show, wherein each of the great shows referred to is counted merely as a unit as against an ordinary Drill Hall meeting, or even a Chiswick Gardens meeting, cannot be considered as otherwise than misleading. At the York and Chester Shows numerous and varied subjects were submitted for award, whereas, as a rule, a Chiswick meeting deals with but a few, or perhaps even with but one subject only.

The only fair comparison, were one necessary, would be between the Northern shows and that at the Temple Gardens, and this affords the following results:—

Awards at the Temple Show	60
Do. at the York Gala and Chester Show (i.e., two shows)	75

Imitating Mr. Alexander Dean, I might say that had the Committee's liberality at the Temple been imitated at York and Chester the awards at the latter would have been 120 instead of seventy-five. But such comparisons prove nothing, the conditions at the several shows being in many respects so dissimilar.

I am inclined to think that few will be found to accept Mr. Dean's estimate of the character and methods of the Orchid Committee. Its members are probably fully as competent as those of the other Committees of the Society, and, with them, equally discharge their duties to the best of their ability. But I am certainly with your correspondent in his suggestion that the granting of awards is "perhaps too free," although it is curious that he quarrels with the Council for saying the same thing. Unless an award is, as Mr. Dean suggests, to indicate only a good average merit, some check must be put on the too lavish manner in which they are bestowed.

Remonstrance, yearly repeated, seems to have no result, and more drastic measures seem called for if the end is to be attained. Would it not be effectively secured by requiring a two-thirds instead of a bare majority as the condition to the granting of an award? And, certainly, a new plant ought not to go forth to the public with the recommendation of the R.H.S. attached to it unless at least two-thirds of the Society's advisers in the matter are of opinion that the plant or product in question is an improvement on existing varieties. A majority of one in a large meeting is surely an insufficient basis for the granting of such a recommendation.—F. R. H. S.

[Many persons will not deem the two-thirds majority proposition unreasonable, nor would they an addendum to it—that all members of Committee should vote in a division.]

STRAWBERRIES AND THEIR CULTURE.

THE Strawberry is very distinct from other Roseworts, as its seeds are borne on the outside, which is the opposite of the Fig, which is a Nettlewort; in fact, a Strawberry resembles a Fig turned inside out. Cultivated Strawberries have originated from our wild wood Strawberry, the Hautbois, the Scarlet, the Pine, and the Chilian Strawberry. All the species are much alike, and are perhaps forms of the same plant, as the difference is mainly in the leaves and flavour.

Strawberries are propagated by seeds and runners. Seeds are only employed for the sake of raising new varieties, as Strawberries cannot be relied on to reproduce the parent. Mr. Knight was the first in this country to raise cross-fertilised Strawberries, and in the year 1818 he had over 400 seedling varieties. Many other persons have followed in his footsteps. Mr. Bradley was the raiser of that most popular variety Sir J. Paxton; Mr. Laxton raised Noble, Latest of All, Sensation, Competitor, Monarch, Leader, and Royal Sovereign; and Mr. Allan raised Lord Suffield, Gunton Park, and Empress of India, all first class either in appearance or flavour with one exception.

The Strawberry rapidly propagates itself by plantlets produced on runners, and many methods are resorted to in securing them for outside planting and for forcing. One of the quickest and best methods is to peg the young plants on the runners into 3-inch pots, and plant as soon as rooted in well prepared ground made firm. If a crop of fruit is wanted the next year, plant not later than the first week of August. Plant the early varieties in a south border, John Ruskin, Noble, Royal Sovereign, Scarlet Queen, and Vicomtesse Hericart de Thury ripening in the order named. Noble dwindles away with us after the third winter, and is, therefore, cleared off after fruiting a second time.

For main crop Royal Sovereign, Dr. Hogg, Sir J. Paxton, President, Duc de Malakoff, and British Queen are free croppers with fine flavour; Laxton's Monarch and Leader promise well, as weak plants put out late in the autumn of 1895 fruited well last year. Competitor, though an immense cropper, is wanting in flavour, and the fruit melts before it is ripe if damp weather prevails. It is not suited for our climate.

For late use there is none better than Latest of All; its name, however, is a misnomer, as there are others later. It is grand in size of berry, cropping, and flavour. Lord Suffield and Waterloo are also very fine; by planting some of each on a north border we have Strawberries in August. To succeed those keep after forcing some of Noble and Vicomtesse Hericart de Thury, which harden in a cool frame, and at the end of May plant on a south border, or better, at the bottom of a wall, never letting the plants want for water. Strawberries may then be had during September, and with a few lights to cover the plants, in October, when they will be much prized for dessert.

Forcing.—Peg the plantlets into 3-inch pots filled with a compost of loam broken fine and horse manure, and when well rooted transfer to 5 and 6-inch pots. The potting material may consist of loam five parts, horse droppings one part, and a good dusting of bonemeal; if the loam is heavy add one part of leaf mould. Some cultivators, after severing from the parent plants, place the 3-inch pots behind a north wall, and likewise the plants after they are placed in the fruiting pots. Except the weather be very hot little is gained, but, on the contrary, time is lost by that practice. Syringe the plants well night and morning till the middle of September, when the nights here begin to get cold and a touch of frost is not uncommon.

When the roots are working freely round the pot weak liquid manure will plump up the crowns; artificial manure also helps if used during August or September. Strong plants potted early often throw up flower spikes during September, all of which cut out as soon as seen, except you want a few ripe fruits for Christmas, in which case house the plants as soon as fruit is set.

Store the plants in cold frames for the winter, or till wanted for forcing. Our first batch goes in early in January. The plants are plunged in a bed of leaves in an early vinery having a temperature of about 50°. After the flower spikes are a couple of inches long the plants are removed to shelves nearer the glass. When the plants are growing freely give a pinch of artificial manure to each pot. Guano I find good, though some persons prefer blood manure. Liquid manure is given at alternate waterings till the flowers commence opening, when another dressing of artificial manure is applied. An occasional supply of clear water helps to keep the soil sweet. Soot and sheep manure make the best liquid. Pigeon manure is good, but dangerous unless used weak.

We syringe the plants twice a day till the flowers commence opening, then cease till the fruit is set, when the syringing is resumed till the fruit commences colouring. If green fly or red

spider show we fumigate with Murray's vapouriser, and find that no injury is done to the delicate flowers.

The varieties which force best with us are Noble, which sets freely no matter how early forced, and gives splendid berries of a fine colour, many being 3 ozs. in weight, and from four to eight on a plant. Royal Sovereign is of better flavour, an equally free setter, but the berries are smaller. Dr. Hogg also does well, giving berries as fine as Noble, a little pale in colour, but excellent in flavour. President and Scarlet Queen set freely; flavour and colour good, but the berries smaller than those mentioned. Vicomtesse Hericart de Thury and John Ruskin are excellent early forcers, and the fruits of good flavour, but much smaller than the three varieties first named. For market Noble and Royal Sovereign are by far the best, and no Strawberries that I know carry the weight of those two combined with appearance.

Do not let the temperature at night exceed 60° till after the fruit is set, when it may range between 65° and 70° if the fruit is wanted ripe quickly. By removing the plants to a cooler and more airy house for a couple of days before the fruit is gathered the flavour is much improved.—W. T., Ireland.

FLOWERING TREES AND SHRUBS.

(Continued from page 154.)

DECIDUOUS.

SOME of the many species and varieties of *Pyrus* have during recent years been freely planted for ornamental purposes, and right well have they repaid the attention bestowed upon them, for not only are they beautiful when in flower but also when their miniature fruits are ripe. The Siberian Crab is a good example of a *Pyrus*, having both these attractions. The flowers greatly resemble those of the cultivated Apple, and the brightly coloured red and yellow fruits are in the autumn conspicuous and tempting in appearance. Some individuals profess to like the taste of these showy Crabs, but I fancy few retain the liking long. *P. floribunda* and *floribunda atrosanguinea* form extremely handsome bushes or half-standards.

When grown in a sunny position the long slender shoots are completely studded with rose and red flowers; small fruits are also freely produced. No one can fail to be delighted with these two. There are several varieties of *Pyrus malus*. Three of the best are Elise Rathe (pendulous), John Downie, and *præcox*. *P. domestica*, although not particularly showy as far as the flowers are concerned, is worthy of being grown on account of the distinctness of the leaves, which are broad, glaucous green on the upper side, and underneath covered with white cotton-like fibre or down. *P. spectabilis* grows quickly and forms a handsome tree, the flowers are large and showy, sometimes pale red in colour, at others almost white with a red tinge.

In *Rhus Cotinus* (Smoke Plant) we have a novel and showy shrub, which produces pale purplish flowers in July, and when the flowering is over the long hairy pedicels form another attraction.

The value of *Ribes sanguineum* for growing in the form of a bush is widely known. To my mind the best position for it is an open one on grass. It then grows to a large size, and the drooping racemes of deep rose-coloured flowers are shown off to advantage. *R. s. atro-rubens* produces flowers much deeper in colour than those of the older form, and *glutinosum* bears larger racemes of pale rose flowers; *album* is worth growing for the sake of variety, although the colour is rather cream than white.

The various species and varieties of *Robinias* are extremely handsome, the Pea-shaped flowers being produced in pendulous racemes, and old trees are quite picturesque in appearance, even when the leaves have fallen. *R. pseud-Acacia* (Locust Tree) is perhaps the most widely known among them, and many an old garden contains a fine specimen of it which in April or May unfolds its countless white blossoms. *R. hispida* forms a pretty dwarf standard, and should if possible be planted in an isolated position, as it grows so slowly that if placed in a shrubbery the other occupants—if not carefully watched—overrun it. The flowers are of a fine deep rose colour, and are produced so freely that it is a good plan to remove some of them to allow those left to be seen to advantage. This *Acacia* is not often seen, and I can strongly recommend it to the notice of all. *R. neo-mexicana* is a recent introduction which is said to be the handsomest of the family.

Among *Spiræas* Anthony Waterer, *ariæfolia*, *Douglasi*, *prunifolia flore-pleno*, and *Thunbergi* are some of the best. *Staphylea colchica* (fig. 39) is a deliciously scented white-flowering shrub, which I have known for fifteen years, and during that time I have only met with it in two private gardens. This is, I think, a matter for regret, as I feel sure that all who see it in flower will be delighted with it.

I do not intend to dilate upon the charms and usefulness of the ever popular Lilac, as they are well known to all who take an interest in gardening. I will, however, enumerate a few of the many good varieties of *S. vulgaris*. *Alba* and *alba grandiflora* are excellent whites, which might with advantage be more largely planted. *Charles X.* is, I think, one of the very best for general planting, as the flowers are massive and of pleasing colour. *Chinensis* bears flowers of a lovely violet shade, which are borne on shoots more slender than those of the majority of Lilacs. We have a large bush growing on a steep bank, and in that position it looks extremely well when seen from below, as the weight of the flowers slightly bends the shoots. *Persica*, *Dr. Lindley*, and *President Grevy* are also good single varieties, and among the double flowered the following are excellent:—*Emile Lemoine*, *La Tour d'Auvergne*, *Michael Buchner*, and *Virginal*.

should be deeply trenched, and a little manure worked into the lower strata as the operation proceeds. Then, when planting is finished, a mulching of manure or leaves ought to be placed upon the surface, with the twofold object of preventing injury through drought in summer time and of encouraging the production of surface roots. Much of the planting to be done in shrubberies is, however, of a different nature, and consists of clearing away old shrubs to make room for the introduction of flowering ones to give colour, or of planting standards at intervals to break up the outline, and thus improve the appearance of existing shrubberies.

If success is expected in these matters no half measures should be tolerated. For standard trees holes from 4 to 6 feet in diameter and 3 feet in depth ought to be dug, so as to give the young trees a good space free from the roots of surrounding ones. A layer of manure and leaf soil should be placed in the bottom of each hole,

FIG. 39.—STAPHYLEA COLCHICA.

Viburnum Opulus (Gueldre Rose), and the dwarf form, *Weigela rosea*, *rosea alba*, and *rosea carminea* complete my list of deciduous flowering shrubs. To some it may seem a lengthy one, but all should be grown wherever room can be found for them, and I feel sure we should see a greater variety in many gardens if those in charge fully realised what a wealth there is to select from.

PLANTING.

It is not often that spring planting can be done under such favourable conditions as those that prevail at the present time, the heavy rainfall during the autumn and winter months having thoroughly moistened the soil to a great depth; and yet so great was the need of moisture that I find our light soil is in exactly the right condition for planting—viz., damp enough to preserve the necessary plumpness in fibrous roots, and yet not wet enough to become "pasty" under the planter's tread. Under such circumstances, of course the proper thing to do is to push on with all possible speed the planting of trees and shrubs of all descriptions, instead of tempting fortune by delaying the operation.

Where new shrubberies or clumps are being formed the ground

and then covered with soil to a sufficient depth to bring the surface roots of the tree to be planted almost up to the ground line, deep planting being an evil to avoid, as also is that of placing manure near the roots of newly planted trees. Other details which require attention are to remove the point of each root with a sharp knife, to spread each root out carefully in such a way that the young fibres may take hold of the soil without coming directly in contact with its neighbour, to tread the soil moderately firm, and to stake securely.

When the roots of trees are found to be very dry on arrival from a nursery they ought to be immersed in water for an hour or so before being planted. At this season newly planted standards ought to be pruned back to two or three eyes, to enable them to make a strong start. In the case of large bushes of such shrubs as *Syringa*, *Ribes*, and *Deutzias*, instead of pruning back each shoot the old branches should be removed and very strong ones shortened to half their length. Numerous suckers are then produced, and but little after-pruning is required for some years. I hope to complete this series by a note on evergreen trees and shrubs.—H. DUNKIN, *Castle Gardens, Warwick*.

EELWORM ERADICATION.

IN order to meet Mr. Bradley's request for information on this subject (page 118), I considered it advisable to compare my statements in the *Journal of Horticulture* with the records of the experiments, and thus ascertain if there were anything to make clear "respecting eelworm in Cucumbers and Tomatoes, and proposed remedies." After carefully going through the evidence I find a complete agreement in substance and in fact between the records of the experiments and the statements, therefore see no reason to amend or reverse anything in the judgments.

Nevertheless, as some growers may not have clearly understood the statements in respect of the proposed preventives and remedies, I will endeavour to "write on maladies and remedies in a way we can all understand." This, as far as I understand Mr. Bradley, means the avoidance of technical references and strict adherence to plain clear terms, for, as Mr. Bradley puts it, "In these days of keen competition we cannot afford to do much experimenting, and then find supposed remedies useless, as in the 10 per cent. of lime treatment. In my experience Tomatoes or Cucumbers could not survive such treatment. I found them dead in twenty-four hours after applying 10 per cent. of lime to soil that Professor Gilchrist pronounced deficient in lime previous to using it."

Why Mr. Bradley refers to the "lime treatment" solely is not "clear," unless it be to connect my statements with those of the talented Professor. I accept the reference as a compliment, and as evidence that there are some of those "unfortunately born too soon for participating in the advantages of such education as is available now in any art or science that a youth may wish to study," who may by self-help grasp the teaching of Science and apply it to practice in a manner totally beyond the grasp of the absolute theorist.

There is no way to acquire useful and reliable information but by work, and no amount of writing in "plain clear terms" will make anything "easily to be comprehended" by idle readers. That is my experience, also that "the best of teaching and the most appreciated" combines science with practice. Indeed, the latter without the former is nothing more or less than a muddle. Instance Mr. Bradley's statement—"Not only does eelworm attack Cucumbers and Tomatoes, but Cyclamens, Primulas, and Carnations suffer from its depredations."

Now, according to such statement we imply the same eelworm, similar preventive and remedial treatment. But Cucumbers and Tomatoes are only infested at the roots, while Cyclamens, Primulas, and Carnations may be attacked both below and above ground. What is there in practice to show that the eelworm is the same in both cases? Absolutely nothing; yet the eelworm may be identical, and the treatment answer in either case. On the other hand, the eelworm on the Cucumbers and Tomatoes may be "root," and on the Cyclamens, Primulas, and Carnations "stem" eelworm. What is the good of practice in such cases? It is guessing at things, which wastes time, labour, and money. Science defines, combines with practice, and makes sure.

In Cucumbers and Tomatoes I have found three forms of eelworm—"Stem," causing nodosities on the roots, chiefly at the extremities; "Blunt," inducing the decay of the root stem, often without producing excrescences, and seldom doing more than "clubbing" the roots; "Root," producing nodules on the roots and swellings on the root stem.

The "stem" eelworm leads a free life in the soil and decaying organic substances, is a parasite only for breeding purposes, not always that, and found in every soil containing dead organic remains. It attacks Onions, rendering them "fuzzy," Cucumbers, Tomatoes, and Vegetable Marrows, in addition to its beloved Clover. The "blunt" eelworm also leads a free life in the soil, and lives on decaying organic substances or their solutions, and attacks Cucumbers, Tomatoes, Gardenias, Cyclamens, Primulas, and Orchids, always at the roots or root-stem. The "root" eelworm roams in the soil when not engaged in breeding, thrives on decaying organic matter or its solution, and infests Cucumbers and Tomatoes at the roots only as a parasite. The period of gestation is one month, and may occur at any period of the year in a hothouse. If the root-plant be killed by the first attack, as young Cucumber plants often are, the larvæ produced in the month may survive in the soil for an indefinite period, living on organic matter in a state of decay or in solution. Whether they can breed otherwise than parasitically I have not been able to ascertain, but there is no reason why, as both "stem" and "blunt" do.

Neither of the three can live in perfectly dry air or soil, survive the ordeal of freezing stiff, nor bear heat over 125°. This I hope is "plain" enough for "Market Grower." I know it does not accord with the mysteries science (save the mark) sometimes wraps around these and other micro-organisms, but I prefer Nature to second-hand natural history.

Thus we arrive at preventives and remedies on a broad and substantial foundation—the eelworm, according to our old friend Mr. Iggulden, is "always with us." The Romans grew Cucumbers, as did the ancient Egyptians before them, and we have grown them in this country for centuries without knowledge of eelworm. Indeed, until the late Rev. M. J. Berkeley detected eelworm in the nodosities of Cucumber roots we were as ignorant of its existence as either the Egyptians or Romans, whereas the geological records show that it must have existed in primordial times.

Why the eelworm has been so much on evidence in recent years may be due, as Mr. Iggulden says, to departure from correct methods of culture, especially in growing for market. Be that as it may, there has certainly been an alarming increase of the pest, and quite as many cases of infection reach us from private as from growers for market, which is not remarkable, as many so-called private growers grow Cucumbers and Tomatoes more for marketing than home consumption, and have adopted market growers' methods. This is a very important consideration from a cultural point of view, as where the old method—the sweet soil and hardy plant—is followed there are few cases of eelworm infection as compared with the express system—the rich soil, sogged and rotten plant.

Under the old régime the soil was never used fresh cut, but always stacked long enough to kill the herbage the turf was cut with, and sometimes each layer was sprinkled with freshly slaked lime to kill wireworm, hasten the decay of the grass, and sweeten the soil, often along with soot to enrich the loam and expel pests. Thus I have known a mixture of equal parts air-slaked chalk lime and dry soot by measure used at the rate of half a pound per square yard, each layer of turves as placed grass side downwards receiving its proportionate share, the thickness being 1 foot for each half pound of lime and soot mixture per square yard, or for a cubic yard 1½ lb. That for rather strong soil, and for light soil turf 4 ozs. of kainit per square yard of 1 foot thickness, 1 oz. on each layer of turf 3 inches thick, and a handful of soot, or four handfuls for the foot thickness.

Either of those after being stacked from late summer or early autumn formed excellent composts for Cucumbers, Melons, and Tomatoes, and the plants were not affected by any micro-organism at the roots. If the loam were not considered rich enough about one-fourth of sweetened horse droppings, which meant sweating the life out of any eelworms that had passed through the animal's digestive canal, was added to the rather strong loam, and one-third to the light soil. These practices, except the kainit, are as old as the English horticultural Adam, and as good now as ever. When kainit was not used, for this is an excellent device of the late Dr. Voelcker, wood ashes, twice as much as of soot, were used with the light loam in stacking, so that there was nearly the same, and in some respect a better compost.

The foregoing remarks will enable those "born too soon for participating in the advantages of such education as is available now" to understand old methods, and compare them in principle and in substance with the new and raw. This, as far as I can see, comprises Mr. Iggulden's "little sensation." He blends the old with modern practice in such manner as to secure a compost as free as may be from eelworm, and so compounded as to produce a healthy, sturdy, fruitful plant on the express system. This breaks down sometimes; then Mr. Iggulden needs assistance—some physic for his plants, such as Little's soluble phenyle. Just so; and its success or otherwise depends not upon "faith," but upon its efficacy, and that on administration according to the instructions.

This brings me to the 10 per cent. of lime treatment. I cannot understand its failure, not in killing eelworm, but the plants in twenty-four hours. Either it was magnesian, or if chalk or a good land lime, such as an analysis is given of on October 29th, 1896, page 424, mixed with the soil and the plants set in it shortly afterwards, perhaps at once, instead of letting lie for a considerable time, say from removing old plants in the autumn to replanting time in the spring, or from mixing with stacked turf in autumn to its use for the earliest planted Cucumbers or Tomatoes in the following year. Something was wrong somewhere, and I am certain it was neither chalk nor good land lime.

As regards my making my statements on Cucumber and Tomato diseases more clear than I have hitherto attempted, I must express my inability. By them as given in these pages, October 22nd, 1896, page 401, I am content to abide, especially the corrosive sublimate solution as a drastic preventive or remedy, and the soluble phenyle as in no wise dangerous, and giving value for expenditure as a manure. Next to this the kainit and nitrate of soda, and for unrivalled cheapness and efficacy boiling water as a disinfectant of soil and houses, and water at a temperature of 145°. This I advise caution with, but it is easy to try it on a few plants, ascertaining the safe heat before applying it on a large scale.

Where labour is a consideration, and fuel dear, the hot water cure is not nearly so economical as Little's soluble phenyle.

The whole are sound—corrosive sublimate the most drastic in effect on the eelworm, but gives nothing to the plant, and is a dangerous poison, therefore I abandoned it in favour of Little's soluble phenyle, and have striven as far as able to place before growers simple preventives and remedies, and ask nothing at their hands but a fair trial on intelligent principles, such as they exercise in their cultural treatment, and perhaps know more about than I do. If they wish to go farther—and I would urge them to proceed only in the direction of that which profits the plants as a manure as well as destroys its enemies—I would point to aniline and naphthaline, keeping within the substances which are compounds of carbon, hydrogen, and nitrogen, and remember that soluble only are safe, and the elements readily available as food of plants. Out of either aniline or naphthaline it would be easy to prepare a proprietary article, but I am content with phenol in the soluble form, and for economic considerations advise its use.—G. ABBEY.

AN OLD AND FRUITFUL GARDEN.

LIKE not a few old fashioned folk, I enjoy a saunter through a garden of the olden type. Not only flowers hardy, beautiful, and fragrant, but fruit and vegetables must grow there, and there, too, I must find the olitory—that garden of simples that our grandmothers were wont to haunt. It happens, fortunately, that I know at least one such garden, and to me a somewhat famous one. It is situated about a score miles west of Charing Cross, on a side slope of a hill, facing south. The charms and interest of a garden are greatly enhanced by its surroundings. To be able to change the focus of vision—to lift the eyes to a distant horizon, whether it be over rolling cornfields, green meadows, or towards empurpled hills; or better still to peep through bowers of Honeysuckle and Roses at a hundred leagues of blue sea, overcanopied by a wider horizon, one enjoys the garden so much the more.

It is not the Italian flower garden that I am about to describe, although that is beautiful, nor the spacious pleasure grounds, but a plot some 6 acres or more half contemptuously designated as the kitchen garden. Now there is a quiet beauty in carefully cultivated vegetables. There is not much to admire, perhaps, in the growth of that homely tuber the Potato; but glance for a moment at that big, green Rose the Cabbage, while the early dew-drops are shimmering in their emerald cups; or the graceful Kail that suggested to the architect the Greek Capitol. Then look at the elegant outlines of the Runner Bean and Pea, of the noble leafage of the Gourd tribe, and the classic elegance of the Celery and Leek. Were these not edible they would have long since have been prized and grown in our gardens on account of their beauty of form.

But let me attempt to describe the genesis of this old garden. Over a century and a half ago two elderly men might have been seen on the terrace of a noble house, once a residence of the unfortunate Monmouth. In front is a beautiful Italian garden, with its statuary and fountains; beyond it a little army of labourers are at work in making a great lawn with sloping woods on either hand. The object is to afford a distant view of the North London heights and a glimpse beyond to the right. After a few minutes they turn and walk up the hill beneath some ancient pollard Oaks. Bluff Harry and Catherine his Queen, when on a visit, would walk that way at times; and a still more famous man, Cardinal Wolsey, would be seen accompanied by a splendid retinue. He would be seated for a time beneath a tree that is still called the "Cardinal's Oak." Of the two elderly men one is Commodore Anson, the other the famous landscape gardener, Capability Brown.

They are about to determine the site of a new kitchen garden. Aspect, drainage, and soil are the desiderata, and here on the slope of the hill they have all three. In front, looking south-west, are just discerned the grey towers of Windsor Castle, and along its base the misty grey line denotes the Valley of the Thames. Sheltered from north and east, open to the south and west, with natural drainage and rich friable loam, here surely is the spot! And that is the garden I shall attempt to describe. I have traversed its broad, smooth, flower-margined paths many a time. It is entirely surrounded by walls and intersected transversely by other walls, the main purpose being protection and wall space for fruit. It was here the famous navigator, Commodore Anson, after ploughing the sea, with the assistance of "Capability Brown" began to plough the land.

The garden is of oblong shape, and all the walks are parallel, or at right angles to each other, with borders of herbaceous plants on either side. No ribbon border of so-called bedding plants could vie for a moment with the interest and beauty of these borders. From Christmas Rose to Chrysanthemum; from Snowdrop,

Daffodil, and Anemone; Pæony, Hollyhock, and Phlox; Delphinium, Hydrangea, Foxglove, and huge Fuchsias to Michaelmas Daisies, which used to be sent by the old Earl and his lady to cheer the inmates of hospitals. Then, of course, there are beds of Roses, Carnations, and Lilies; and just as the Roses are in bloom we—no, his Lordship's family—have only to step over the border to luxuriate in the most delicious Strawberries. Here they are in abundance, from Keen's Seedling to La Constante and Royal Sovereign. And then, what a feast of the plebeian Gooseberry is there in the season! and, as in the case of Strawberries and Currants, protected by means of careful netting. In the more sheltered parts of the garden are quarters of Cherries, Plums, Apples, and Pears. Most of these trees are pyramids, from fifteen to twenty years old; and among them, as one may see by the label, are the choicer sorts, added by Mr. Mundel, the late highly esteemed head gardener, as they came out. Of Pears there is a fine collection. Along the upper walk by the houses is a row of dome-shaped trees, the branches trained down. They are a feature in the garden, although several of the kinds, among them Marie Louise and Beurré Diel, do not take kindly to this kind of training. The trees were about 8 feet high, and from 5 to 6 feet through. They are very handsome when in flower. Both the Apples and Pears are beautiful objects in blossom—no two blooms precisely alike. Beautiful as these trees are in April and early May, they cannot vie with the Cherry, and more especially the Morello Cherry, whose silver bells the bees are ringing from dawn to sunset.

It is difficult to understand the prejudice against fruit trees in the pleasure ground. There are few more delightful objects on a lawn than a well-furnished Apple tree; and, indeed, there are few more beautiful trees for flower and fruit.

The first long range of glass is used as a fruit house—for Peaches and Nectarines mainly. It is an agreeable surprise when one steps out of the keen March air into such a little world of sunshine. The masses of lovely pink blossoms are open then; there is the suggestive fragrance, and the soothing hum of hundreds of bees busily at work. The gardener, as a rule, thinks little of the value of these humble creatures. Without their aid in fertilising the flowers he would look in vain for the crop that follows. George Herbert has some quaint lines on the bee that may not be known to some readers:—

"Bees work for man; and yet they never bruise
Their master's flower, but leave it, having done,
As fair as ever, and as fit for use;
So both the flower doth stay, and honey run."

This is scarcely the truth, by the way. In some species of flowers the petals drop soon after the blossom is fertilised, so rapidly is the function completed.

It is probable that the fruit grown on the walls here during the past half century would, if sold, have paid more than thrice over for the cost of the walls. Peaches, Nectarines, and Apricots are grown by thousands. The bloom on the open walls is protected from frost, and there is scarcely ever a failure.

Much more might be said of this fruitful old garden, of its fine crops of Muscats and Black Hamburgs, its Figs and forcing houses, and plants, and also about the pretty geometrical garden close to the entrance to the second garden. If the old Commodore and Capability Brown could visit that spot once again it would gladden their eyes to see their labours matured, the garden still flourishing in its green old age.—HERGA.

OUR HARDY PLANT BORDER.

(Continued from page 153.)

SWEET WILLIAMS.

THESE old garden favourites, which in some districts may be seen near almost every cottage, are still worth a place wherever beautiful flowers are prized, though they are specially adapted for certain positions. For example, where there are narrow borders skirting a shrubbery they make a good margin, while we have also had them as a margin for large circular beds, the central portion of which has been devoted to sub-tropical plants. They are not adapted for beds laid out in geometrical design, nor for any elaborate series of beds on terraces in view of the mansion, unless they can be removed immediately after flowering and their places filled with some other suitable plants. In very hot seasons and dry situations they last but a comparatively short time in flower, and the tall seedy stems then have an untidy and dreary appearance. For lines and masses, however, in less conspicuous places they are unquestionably most useful, and they have much to recommend them for general cultivation.

One of the reasons that induced us to include them in our collection was because they are easily raised from seed, thus.

enabling us to secure some thousands of plants to form large beds in the long border we had to fill. When the varieties of Sweet William (*Dianthus barbatus*) were distinguished by names like other florists' flowers, increase by cuttings or layers was necessary, and raising a large supply was a rather tedious business; matters are very different now, however, for the attention paid to the improvement of seed selection has resulted in a great advance. It is no exaggeration to say that from a packet of the best seed, such as that sent out by all the leading houses, it is possible to have numbers of varieties quite up to the old florists' standard as regards size, regularity, and colour of the flowers.

Familiar as we have long been with the advance made in the mixed seed strains of popular flowers, we have repeatedly been astonished by the high quality of the seedling varieties thus obtained amongst Sweet Williams. Many a bed we have had that presented quite a study in itself, both for range of variation in colouring and size; the individual flowers even and bold, the trusses large, compact, and effective. Because they are "common" flowers, they are yet by no means "common" as regards their attractions, and few of the easily grown plants present so many characters worthy of note. Nor is it only at the flowering time that the plants are worthy of notice, well-grown bushy specimens are ornaments in a border throughout the winter months. The vigorous healthy growth is in a measure the cause of this, but the tints assumed by the leaves are the chief feature.

The dark and light coloured flowers are respectively attended by dark and light foliage, and in the former case the leaves become of a rich bronzy red that is singularly effective when there is little colour in the hardy plant borders. In contrast with the dark red shades we have various tints of green, some being exceptionally bright and lively, very distinct from the ordinary greens of winter foliage, and more resembling the fresh hues of spring buds. Such are some of the attractions of these plants, but no one can grow them in quantity and with the object of studying them without discovering other qualities of interest.

The seed should be sown as early in May as possible, in fact similar treatment to that needed by Wallflowers is requisite, but we have found this difference—namely, that far better plants result from seedlings only once transplanted than from those which are shifted twice. The sooner the seedlings can be placed in the permanent quarters when they have made sufficient advance in the seed bed to be easily lifted the better is the growth produced before winter checks their progress. It is also important to sow the seed thinly, and even then it may be desirable to thin the seedlings, as any approach to a drawn, weakly condition must be most carefully avoided from the first.

A well-dug but moderately firm soil, enriched by a liberal dressing of old farmyard manure some time previous to planting, is the most suitable for producing strong plants, but a slight additional dressing of superphosphate (about half an ounce to the square yard), applied in December or January when the weather is open, has resulted in the production of finer trusses and flowers than where this was omitted. We have also thought that the colours have been both richer and clearer where this mineral manure has been used. Without the farmyard manure double the quantity of artificial has not produced quite the same effect, except in cases where the soil was fairly rich from the residue of manure left from previous crops. Nitrate of soda appears to be too stimulating for Sweet Williams, for though tried at various times and in different quantities the results were not so satisfactory as where the plants were allowed to make a more natural and sturdy growth. If once they become "drawn" they are comparatively useless.

ARABIS ALBIDA.

The early flowering pure white Arabis is most valuable for an edging to large borders, and we have raised many thousands from seed sown in late spring or early summer which produced excellent plants, that were flowering profusely by the end of the following February. So vigorously do the plants grow in our soil and under the particular treatment tried, that several friends well versed in hardy plants have failed to recognise this as the ordinary Arabis alba when it is not in flower. The leaves are considerably larger than the usual type, the plants forming cushion-like tufts about a foot in diameter and the flowers large, and produced on stout stems quite clear of the foliage. At the present time (February 24th) some of these are flowering most abundantly, and we have counted as many as 150 spikes on one plant.

The seed has been sown at various times, from April until early August, and in fine autumns good plants have been secured from the later sowing for flowering in the following year; but when the time can be devoted to "pricking" out the seedlings as soon as they are ready, the April sowing gives the best results. This also enables the young plants to recover themselves before the heat of summer is upon them—an important matter, for though this plant

will grow and thrive upon rockeries, yet in the young state a dry situation or soil seems to be positively injurious. Upon the edge of a raised border the plants grow admirably, extending to the path level, as while being moist and cool excessive rain can readily escape. Superphosphate has a surprising effect upon this plant when used only at the rate of half an ounce per square yard, and after trying it several times upon plants, in contrast with others that received nothing in the shape of manure, we always employ it now.—A COUNTRYMAN.

(To be continued.)

CHEMISTRY IN THE GARDEN.

(Continued from page 90.)

HAVING in the previous articles briefly described the elements found in plants, let us now turn our attention to the substance known as soil. In considering soil we shall find it necessary to turn on side lights from other sciences, for the purpose of giving more illuminating power to our thoughts on its chemistry.

THE ORIGIN OF SOILS.

Astronomers tell us that millions of years ago our earth existed in space as a mass of glowing gas. Gradually this gas parted with some of its heat by radiation, and as the temperature fell some of the substances which were in the gaseous state condensed, and became liquids similar to molten lava. On further cooling the liquids became solids, and so formed the primary rocks of the earth.

After the first rocks were formed, the earth was no doubt so hot as to make it impossible for water to exist, except as watery vapour (steam) in the atmosphere; but as the temperature of the rocks gradually decreased the vapour condensed into water and descended to form rivers, seas, and oceans. There are still some gases left surrounding our earth—namely, those which constitute our atmosphere; but any of these can be made to assume a liquid, and even a solid form, by subjecting them to a very low temperature. The primary rocks consisted chiefly of granites, syenites, and basaltic rocks, and when first formed were of a more or less crystalline character. Our object, however, does not lie so much with the geology of the rocks as with their chemistry, so before proceeding we will give the chief constituents of which they are composed. The granite rocks generally consist of the three following substances—quartz, felspar, and mica.

QUARTZ consists of but two elements—namely, silicon and oxygen. By the decay of the granite rocks the quartz would be liberated as grains of silica or sand.

FELSPAR is composed principally of silicates of alumina which are present in chemical combination either with potash, soda, or lime. There are, however, nearly always traces of magnesia, oxide of iron, and phosphoric acid also present.

MICA is not unlike felspar in composition. It consists chiefly of silicates of alumina in combination with magnesia or potash. There are large quantities of oxide of iron also present; but soda, lime, and phosphoric acid are entirely absent.

SYENITE is a variety of granite, in which there are but traces of quartz; and the mica is replaced by hornblende.

HORNBLende consists principally of silica, iron and lime, together with smaller quantities of alumina, potash, soda, and phosphoric acid.

BASALT is a dense heavy dark coloured rock, consisting either of a mixture of felspar and hornblende, or felspar and augite; the last named being a substance formed by the union of silica with magnesia.

Seeing what very important substances felspar, mica, and hornblende are in the composition of rocks, we think it advisable to give the chemical composition of the three minerals just named:—

ANALYSIS OF MINERALS.

		Felspar.	Mica.	Hornblende.
Silica	...	65.72	46.36	43.45
Alumina	...	18.57	36.80	6.52
Potash	...	12.32	9.22	2.86
Soda	...	1.25	none	3.27
Lime	...	0.34	none	10.25
Magnesia	...	0.10	3.09	3.56
Iron Oxide	...	none	4.53	29.98
Phosphoric Acid	...	1.70	none	0.11
		100.00	100.00	100.00

These analyses show us what a large quantity of silica and alumina there is present in the minerals, and also what a large amount of iron oxide hornblende contains. The large quantities of potash in felspar and mica, and the 10 per cent. of lime in hornblende is also very noticeable, showing us that the first two named

minerals would form a soil rich in potash but poor in lime, while the last named would form a soil poor in potash but rich in lime.

By the action of the disintegrating agents, which we shall consider when dealing with the formation of soils, the exposed surface of the crystalline rocks was broken down, and the loosened particles were carried by rivers into the sea, where they settled down to form sedimentary rocks. We have therefore two classes of rocks—namely, the primary, formed by the action of fire, and known as igneous (Lat., *ignis*, fire); and the sedimentary, formed by the action of water, and called aqueous (Lat., *aqua*, water). Another very important class of rocks, formed after those just named, are the limestones and peat beds. The limestone rocks were formed by the deposition of shells and other calcareous matter in the ocean, and the peat beds were formed by the accumulation of vegetable matter in wet situations.

The sedimentary rocks, after being under water for thousands of years, were raised and became dry land. All the exposed parts of rocks are constantly being attacked by the various disintegrating agents which pulverised them, and the material thus formed may be looked upon as rotted rock or soil. Soil, then, is the name given to the more or less powdery substance which we find covering the surface of rocks.

On page 91 a correspondent signing himself "Henri" calls my attention to a paragraph on page 47, which he says "seems wrong." The portion referred to is as follows:—"During growth certain chemical changes are taking place during which oxygen is absorbed and carbon dioxide is exhaled." Your correspondent, after quoting the above passage, asks two questions—viz, "(1) Is it so? and (2) Should it not be, Carbon dioxide is absorbed and oxygen exhaled?" To the first question I answer, Yes; to the second, No.

By again turning to page 47 your correspondent will find that I say in the next sentence to the one which appears to him to be wrong, "This interchange of gases is called the 'respiration' of plants." Plants also absorb carbon dioxide (CO_2) from the atmosphere, and, under the influence of sunlight and the chloroplastids, this gas is broken up, the carbon being retained and the oxygen exhaled. This interchange of gases is known as the "assimilation" of plants, a subject which will be subsequently dealt with.

Now, my friend, again take up your "Oliver's Botany," and see what he says about the respiration of plants, and I think you will find that the statement on page 47 is perfectly correct.—W. DYKE.

A GARDEN IN THE ISLE OF WIGHT.

[An Address (amplified) by Rev. H. EWBANK to the members of the Horticultural Association at Newport.]

(Continued from page 141.)

It has been such an absurd attempt on my part to give representative flowers for the different seasons of the year that I feel I must now withdraw from it altogether. Time and space are against me, and the Eremuri, the Calochorti and Ixias must not be offended if they are passed over in silence. I only wish to say a word about rock plants, for they have a great attraction of their own. It is wonderful that they succeed as well as they do when we consider how different are the conditions under which they grow naturally from those under which they are here. In Switzerland and other countries they are buried deeply in snow for many months of the year, and then they are exposed from June onwards to most brilliant sunshine and long stretches of settled glorious weather. Here in England they are teased by snatches of fine weather, which make them grow prematurely, and at the wrong time of the year, and then all of a sudden frost and snow come on them in an utterly unprotected condition, and they have first one thing and then another against them all the year round. It is in summer often worse for them than in winter, for the sun has a power here which some of them are scarcely able to resist.

Still they get on somehow, as I have said just now, for there is a wonderful power of accommodation in plants, and they prosper far better than one could have thought of before the trial was made. In one way and the other I must have 5000 plants in my rockery, according to a computation which my gardener and I made a short time ago, for it is impossible to tell with certainty about it.

A condition for success is that the roots should run back a very long way, and derive sustenance from hidden stores of nutriment which are far away out of sight. Thus a plant 1 inch high will go forty times deeper than it will venture to appear above ground, and when you wonder how such a gem as *Eritrichium nanum* in Switzerland, or elsewhere, can stand the summer sun, it is sometimes forgotten that it draws upon hidden stores of food by its long and tiny rootlets. Then, again, stones on the mountain sides, and the *débris* of ages prevent evaporation. The state of things in England during the summer is often very much dried up, and mischief must sometimes be prevented by a mulch of leaf mould and silver sand, and by a coating of small stones, which does great good.

Very often it is good practice to grow a plant in a horizontal position. It sends the water off the foliage, and keeps it from rotting better than anything else can do it. Thus *Lithospermum graminifolium* and *Ramondia*

pyrenaica (fig. 40) submit to treatment of this sort, as may be seen in Kew Gardens with *Ramondia*, and there is great gain from it. But, of course, the first thing in growing alpine is to consider what sort of home you can give them, and this is a matter which involves considerations of taste, and also of space and money. There are two kinds of rockeries in this country, and none other need be considered. One is where everything is made to give way to the appearance of the rockery itself, and a miniature Mount Blanc or Monte Rosa is contemplated, and this let me say is for the most part very expensive, and whensoever it is badly done it can be very cockneyfied. It also takes a great deal of room to carry it out at all with effect.

The other way, and it is that which I exclusively advocate myself, is to give up all ambitious projects entirely, and to consider not what you think good and beautiful yourself in the way of a rockery, but what the plants themselves would like, and how best they are to be treated. The

FIG. 40.—RAMONDIA PYRENAICA.

sort of rockery which I allude to is something in the way of that which obtains in the Royal Botanic Gardens in Edinburgh. It is in no sense whatever an imitation of a mountain range, but it is a good and fitting receptacle for plants, and that is all that is wanted. My rockery looks more like an old crumbling ruin than anything else, and visitors have often compared it with an old Roman amphitheatre, which it does in a way resemble.

The advantages are these:—A construction such as mine costs a great deal less than an artistic rockery. From first to last I do not suppose that I have spent more than £40 or £50 on it, whereas thousands can be easily poured out in the other way of making mountains to order. I have innumerable little square pockets here into which the plants lovingly nestle, and where they can be watered with effect, which is a very great point in summer time, and on this account they prefer level spaces to an inclined plane. Moreover, there are a great variety of aspects, and shade is more easily procured than in any other way; and also the differences of taste in the way of soil can be accounted for. It is true that before it was properly clothed the whole thing looked very bare and unsightly, and many hard things were then said of it; but that is not at all the case now, when results have declared themselves.

The proof of the pudding is in the eating, and I invite you all to come and inspect my rockery whenever you like. A low wall surrounds it of about 2½ or 3 feet in height, and there are innumerable holes and interstices made in it by the simple expedient of leaving out every alternate brick, which exactly suits some alpine plants.

I must say a word about a very practical matter which I think should concern Islanders very much; it is the most important part of the address which I have the honour to make to you. I refer to the adornment of our houses and churches and public buildings all over the place with climbers, and our gardens with shrubs, which for the most part at present have no place in them at all. Few persons in the Isle of Wight know what its wonderful capabilities are, and the reason is because they have never tried them. We go on in a very fixed, stereotyped sort of way, and we miss the variety, the interest, and the beauty which might so easily abound. Since I have been living in the island—and it is now forty years since I came to it—I have only known three persons who really took this matter to heart, and can be said to have studied it. Dr. Salter was one, who was the co-editor with Mr. A. More of the "Flora Vectensis." Sir Lawrence Peel was another, but he was principally devoted to trees; and Sir W. Hutt was the third.

I do not, of course, say but that there are many lovers of flowers in the island. Mr. Jeans and Mr. Spittall might be mentioned at once, but so far as I know their strength is mainly devoted to growing Roses for exhibition, which is a very different thing from what I am speaking of. What I desire is to find out what will live in the island, and what will not live in it. It is absurd to have no better selection than may be found in Northumberland or Durham, and yet how seldom a new shrub or flowering tree is introduced into the place. There is the same eternal round of *Passion Flowers*, *Clematis montana*, *C. Jackmanni*, *Cotoneasters*, and *Myrtles* wherever you go. Now these, though very good in their way, are not everything that will grow in the Isle of Wight; nor are they the highest form of ornament which the place will admit of. There is an immense fund of beauty and brightness on which we can draw if we like, and it is our own fault if we stick to a very narrow circle indeed, and never go beyond it.

(To be concluded.)

A CALL AT PENRHYN.

CALLING at these gardens recently I was much interested in some fine examples of the above comparatively new Grape. The bunches had been cut from the Vines and were arranged in bottles in the fruit room, and excellent samples they were, with large berries, reminding one of a white Gros Colman. The quality is good for a late-keeping variety, and where white Grapes are in request late in the season it should prove invaluable. Mr. Speed's opinion is that it requires heat to bring it to perfection like all white Grapes. Evidently its successful treatment is understood at Penrhyn.

By the side of Lady Hutt were arranged some handsome bunches of Muscat of Alexandria; surely they must have been from 3 to 4 lbs. weight, of beautiful finish, and with that appearance of excellent condition that all well-grown examples preserve. Lady Downes' Seedling was equally good of its kind. The wood of the Vines looked promising—Mr. Speed's faggots—jocularly so called from the methods this able cultivator pursues of constantly working in young wood from bottom to top, a sort of compromise between the long-rod and spur-pruning systems. Mr. Speed's opinion is that it maintains vigour and longevity in the Vine, and judging by the results, and the age of the Vines, many of which are from forty to fifty years old, there is ample food for reflection, when one often sees vineries replanted several times over in less than that period.

It was my pleasure to see here one of the grandest batches of Queen Pines I have ever come across—fine sturdy fellows, that gave promise of something superb for the London season, such plants of which any man might well feel proud. A house full of useful late Chrysanthemums was noticeable for their beauty. Forcing plants and flowers were in plenty, while in the Mushroom and forcing houses was abundance for the inner man.

All occupants under glass were well in hand, ready for their respective seasons, noteworthy by the cleanliness and order everywhere prevailing. Outside the same painstaking care and energy was apparent, the bold and skilful planting being highly interesting, even during midwinter, amid a driving storm of sleet and snow. In the flower garden, on one of the walls, was *Lapageria rosea* carrying sundry blooms—a novel sight under the conditions.

It would be unfitting to close these few notes without referring to the residence recently erected for the young men in the gardens, fitted up with every consideration for their comfort and convenience. They will, I am sure, fully appreciate Lord Penrhyn's kindness and thoughtfulness in erecting this splendid building for his employes. So ended my call at Penrhyn, always interesting with its bold grandeur and diversified attractions, so well kept by the straightforward practical man who so skilfully controls it. My sincere thanks are here tendered to him and all of his for their kindness to a wanderer on the way.—J. J. CRAVEN.

VIOLET MARIE LOUISE.—I am sending a small bunch of Violet Marie Louise which have been taken from plants growing in a cold frame. We have been picking from the same plants since September last.—JAMES HOUNSLOW, *Headfort Gardens, Kells, Co. Meath*. [The blooms were of exceptional merit, and perfumed the sanctum for several days.]

MRS. JOHN LAING AND MRS. R. G. SHARMAN CRAWFORD.

THERE are not many Hybrid Perpetuals that have reached the distinction or enjoyed the popularity of Mrs. John Laing. Perhaps its only rival among Roses of its class is the almost invincible A. K. Williams, the most beautiful in colour and the least faultless in form of Hybrid Perpetuals, generally supposed to have been a derivation from that great beauty Alfred Colomb. Another of its rivals, the fragrant La France, has been relegated to the new race of Hybrid Teas.

Raised by Mr. Henry Bennet in 1887, Mrs. John Laing rose rapidly into eminence, and has for many years been a supreme favourite with Rose cultivators, and especially with exhibitors. Its merits are so great, it has so many attributes of the highest description, that it is of equal value for the decoration of the garden and for effective exhibition. I presume that few first prizes have of late years been won at the Crystal Palace by the great English rosarians without its assistance. Madame Gabriel Luizet, notwithstanding its sweetness, has been almost eclipsed.

There is, however, an Irish Rose which, by reason of certain important characteristics, promises ere long to prove a worthy rival to Mrs. John Laing. I refer, of course, to that beautiful and free-flowering Hybrid Perpetual entitled Mrs. R. G. Sharman Crawford, raised by Messrs. Alexander Dickson & Sons, of Newtownards, in 1894, regarding which, and its relation to Mrs. John Laing, a distinguished rosarian who has made a special study of both varieties, and grows them extensively, writes to me as follows:—"I do not think there can be two opinions regarding the high merits of Mrs. R. G. Sharman Crawford. Only in one point can Mrs. John Laing surpass this variety, and that is at times a question. I take the point of individual blooms, and here, when the English Rose is at its best, it would beat the Irish one; but on all other points Mrs. Crawford quite eclipses Mrs. John Laing—viz., in habit of growth, colour, and floriferousness. Indeed, with the exception of Mrs. W. J. Grant there is no Rose more free flowering in the Hybrid Perpetual and Hybrid Tea sections."

A pure pink H.P. with the colour of Bridesmaid (which would, I feel certain, greatly charm John Ruskin), and the beautiful form and graceful habit of Mrs. Sharman Crawford, would be a great acquisition; a very near approximation to perfection.—DAVID R. WILLIAMSON.

THE YOUNG GARDENERS' DOMAIN.

CONSERVATORY MANAGEMENT.

(Continued from page 146.)

FUCHSIAS and Coleus will be the next tenants for the conservatory. Old plants of Fuchsias which have been resting during the winter should be started in February. When they have commenced growing repot in a rich compost. When the shoots are about 3 inches long take out the points. This operation can be repeated about May, keeping all the flowers pinched off in the meantime to insure stronger growth. Afford a liberal supply of liquid manure, and by the time they are wanted they will be splendid plants. Smaller plants may be raised by striking cuttings in September, afterwards placing them on a shelf in a cool house for the winter, potting in spring. Cuttings may also be rooted in spring. For this purpose a few old plants should be placed in heat, and the shoots taken off as soon as long enough for cuttings.

Coleuses may be grown from cuttings taken in January. When rooted place in 3-inch pots, take out the points to insure a number of breaks, and grow in a steady heat. As soon as they are sufficiently rooted transfer to 7-inch pots, using a good compost, and stand in a warm frame. With judicious treatment they will make bushy plants by the beginning or middle of June, when they may be removed to a sunny position in the plant house, supporting them with weak liquid manure. By the middle of July they will be fine sturdy well-coloured plants. A number of standard Coleus may also be grown, by allowing the main stem to grow and taking out side growths until they reach a sufficient height, when the lateral shoots may be allowed to grow. These plants should be grown in 9-inch pots, using a rich compost.

Tuberous-rooted Begonias will enrich the conservatory during this season. *Kalosanthes coccinea* and *Uriah Pike* Carnation will also form an additional attraction. A supply of annuals, including such as *Petunias*, *Balsams*, *Celosias*, *Nicotiana affinis*, *Salpiglossis*, *Schizanthus pinnatus*, and others, will help to keep the house gay for some time. For edging purposes *Isolepis gracilis* and *Mimulus* are serviceable. Abundance of air should now be admitted night and day. The collection just named will continue during the succeeding two months. In September the shading may be taken down. Towards the end of this month a little heat should be kept in the pipes and the ventilators closed at night. This will benefit the Fuchsias, and also prevent the Coleus dropping their leaves.

A few Bouvardias grown after the manner described by "Dunelm,"

page 547 (last vol.), also Lantanas grown under much the same treatment, also a few pots of *Lilium lancifolium*, will add very much to the beauty of the house, succeeding the Begonias or any of the annuals which have become unsightly. A few early flowering Chrysanthemums will also be very good additions. Not much more can be done until the general collection of Chrysanthemums is introduced. This will be about the middle of October. The Fuchsias may then be put under a stage to root. Do not allow them to get too dry, but water them occasionally during the winter. In spring they may be pruned and started as previously stated. The Coleus, from which cuttings should have been taken early in September, may now be thrown to the rubbish heap. The cuttings having been rooted in a warm frame in 4-inch pots may be placed on a shelf in the stove. Take out the points, and they will then make good plants from which to raise the stock for the succeeding year's work. All plants should be cleared out of the conservatory in October. The climbers will then have finished flowering, and should be pruned. Take out all superabundant growth, retaining sufficient to furnish the girders with green foliage. Destroy any insect life which may appear, and clean the house thoroughly.—P. W.

(To be continued.)

BEGONIA GLOIRE DE SCEAUX.

FEW plants give better results for good culture than winter flowering Begonias. Take, for instance, Gloire de Sceaux; if the plants are cut down in April, and given little or no water for three weeks or a month, then placed in a house with a little bottom heat, they will soon produce growths from the bottom. In taking cuttings select the stronger growths and insert them singly in thumb pots in a light compost of loam and peat, or leaf soil, with a good dash of sand. Place them in the propagating pit under bell-glasses, and as soon as they are rooted pot in large 60's, and grow the plants in a temperature of 60° to 65°. Great care must be taken not to let them get dry at any time, but avoid overwatering.

Before the plants are root-bound shift them into 32's, in a compost of two parts fibrous loam, one part rough peat, and one part leaf soil, with a little dried cow manure and coarse sand. Pot lightly, and keep them in moist temperature of about 65°. When the plants are about 1 foot in height pinch out the points, which will induce a bushy habit. Keep the stages and floors of the house damp, and syringe lightly in hot weather.

Lightly fumigate the house about every three weeks, as they are very subject to small white thrips invisible to the naked eye, which, if not checked, play sad havoc with the young foliage, and prevention is better than cure; when flowering commences (which will be in November or December) keep the plants in a temperature of 50° by night and 55° by day, and they will afford a display of bloom equalled by very few plants, and lasting four months.—F. T. W.

CROTON CULTURE.

THESE beautiful foliage plants rank among the best for decorative purposes. Plants now in 5 and 6-inch pots may be shifted into others two sizes larger, using a compost of two parts fibry loam, one of rough peat, and half a part of coarse silver sand. Do not reduce the balls too much at this season, the removal of the old crocks and the surface soil being quite sufficient. Withhold water until the roots begin to move, but use the syringe freely. Any plants which have become tall but have good tops may have these rooted by cutting a notch or two in the stem close to the foliage, and binding round into a ball with sphagnum moss, placing a little sand in it to come in contact with the notch, and keeping moist. This helps the rooting process.

When roots are emitted the stem may be cut through close to the moss. Without disturbing the roots place in pots suitable to the size of the ball, and plunge in bottom heat for about three weeks. The roots will soon enter the fresh soil, when the plants may be taken back to the stove. Cuttings may also be inserted in thumb pots in February or March, choosing clean, healthy, well-coloured shoots. A propagating case where a bottom heat of 70° is maintained is suitable for rooting them. When well rooted they may be removed to a shelf near the glass. In a short time the plants will be ready for a shift into 3-inch pots, using a compost of fibry loam, peat, and sand, without the addition of leaf mould. Stand the pots on shelves near the glass in a low house, and shade for a week or more from bright sunshine. If the soil is in good condition no water will be required for some time, but the syringe must be used twice or thrice daily in bright weather, also the floors and staging should be kept damp. A temperature of from 75° to 80° by day with a rise of 10° from sun heat, and a night temperature of from 65° to 70°, will be suitable. About the middle of May the plants will be ready for 5-inch pots, and may be grown in the same house till September, and then taken to the stove for winter embellishment.

Later in the season a few of the small-leaved varieties may be propagated and brought on in 3-inch pots, these being useful for intermingling with the larger ones in various forms of decoration. Another batch should be propagated in August and placed in 3-inch pots about the middle of September; they will get well established before the dull weather sets in, and make useful plants by the following autumn. However, a few may be kept in thumb pots through the winter, as these have a very pleasing appearance in the rockwork of a large table centre. Large plants, if desired, may be cut back fairly hard and allowed to break, when they should have the soil reduced, and placed in fresh in the same sized pots. The second year a top-dressing would be ample.

Crotons revel in abundance of heat and moisture throughout the growing season, and shading is necessary in very hot weather. Air should be admitted freely from the beginning of August to the middle of September to allow of the plants becoming to some extent hardened and highly coloured. All shading must be removed by the 1st of September. Crotons are subject to the attack of thrips, red spider, and mealy bug. Against the former fumigating with tobacco paper is an effective remedy; the latter succumbs to a solution of soft soap and petroleum, 4 ozs. of the soap to wineglassful of petroleum to 1 gallon of water. The smaller plants may be immersed in a tub of the solution at a temperature of 110°; the larger plants should be laid on their sides, and the insecticide directed into their points by means of a syringe or pump. A few good varieties for all-round purposes are Prince of Wales, angustifolius, interruptus aurea, Warreni, Chelsoni, nobilis, Langi, majesticus, Princess of Wales, Sunset, Clarki, and Victoria. These, among many others, are invaluable through the winter, when flowering plants are scarce.—LEARNER.

GLOXINIAS.

WHILST reading "Youngster's" article (page 144) on the above subject I was surprised at the method of culture recommended by him. In the first instance he seems inclined to deplore the fact that Gloxinias are not largely grown. I can assure him that they are grown in quantity in many establishments. In the gardens where I have been employed, and in various others that I have at times visited, I have invariably found a goodly number of Gloxinias. I have occasionally seen houses devoted solely to them. Farther on "Youngster" says, "As soon as the tiny seedlings can be fairly seen prick them off." I think it more advisable to leave them in the seed pans till one or two rough leaves are formed; they can then be easily handled by a careful man.

Then, again, a cool greenhouse would not be a suitable place for storing the corms throughout the resting period. The temperature of that structure would fall much too low to keep them sound and healthy. A stove or intermediate house would be the best situation for them. For starting the corms into growth at any season a temperature of 50° would not be sufficient; 60° to 65° I find suitable to start them in, certainly not more than 5° lower. Gloxinias are very partial to genial moist heat, therefore I consider they ought not at any time be subjected to a temperature less than 55°.

For potting compost "nothing suits them better than a mixture of three parts leaf soil, one each of loam and sand, with a sprinkling of soot added," says "Youngster." I venture to state the following mixture will be found more adapted to meet the requirements of Gloxinias:—Good fibry loam and peat two parts each, well-decayed cow manure, leaf soil, and sand one part each. Soot is best applied in liquid form. Weak doses given twice a week, commencing when the pots are filled with roots, prove an excellent stimulant. We grow Gloxinias by the hundred, as they are much in demand both in a cut state and as pot plants. By starting them in successional batches we have abundance of bloom for over six months. One and two-year-old corms are used for early and midseason supplies, these being followed by young plants raised from seed sown in the previous February.—W. P.

SNOWDROPS.

SNOWDROPS are well known, and who does not love them? They are the acknowledged chief heralds of spring, producing their light green leaves and white bell-shaped flowers while dreary winter has scarcely left us, and while there are but few flowers out of doors for companionship. In the language of flowers the Snowdrop is the emblem of hope.

There is an old world legend which tells us how Hope chose the Snowdrop for her emblem; that Hope, with her long, golden hair dishevelled, stood one day leaning upon her anchor, watching the snowflakes fall down upon the earth; that Spring stood beside her, and Hope said the earth would look much more cheerful if instead of snow which melted and left the woods and fields dark and damp, the snowflakes were changed to white flowers as soon as they reached the earth; that Spring smiled as she listened to Hope, and sending her sweet warm breath amongst the falling snow it fell in the form of flowers, and so the Snowdrop was first made, that Hope caught the first flower as it fell, and said it would be her emblem throughout all time.

Galanthus, the botanical name of the Snowdrop, is derived from *gala*, milk, and *anthos*, a flower, in reference to the milk-white flowers. It belongs to the natural order Amaryllidaceæ, other members of this order being *Leucoium*, *Narcissus*, &c. Of the species and varieties in cultivation perhaps *G. nivalis* and *G. Elwesii* are the best known. Snowdrops are of easy cultivation, and will thrive in almost any soil or situation. For naturalising in grass, by woodland walks, and under deciduous trees they are very suitable, and they are both cheap and attractive. If planted in the autumn they will make a good show the next February. When once planted they should not be disturbed. They will soon establish themselves, and will come more plentiful every year.

I often wonder why Snowdrops are not more used for naturalisation in public gardens and the gardens in the squares of our large towns, where at the present time they are devoid of flowers from November till May. Nothing could be more attractive at the present time than in the midst of the grim and black appearance of these gardens to see patches of Snowdrops here and there, reviving the spirits and giving fresh hope to those who look upon them.—CAMEO.

FRUIT FORCING.

Cherry Houses.—Ventilation is the main art in forcing Cherries, and requires unremitting attention. A free circulation of air should pass through the house whenever the temperature exceeds 50°, regulating the amount by the conditions of the external atmosphere. Employ fire heat only to maintain 50° through the day, relying on sun heat for advancement, and maintain a night temperature of 40° to 45°. The blossoming over and the fruit swelling, recourse may again be had to syringing; but avoid keeping the trees dripping with water, always allowing the foliage to become fairly dry before night. Keep a keen eye on aphides, and promptly fumigate or syringe the trees with quassia water. This may be made by steeping 4 ozs. of chips overnight in a gallon of soft water, boiling fifteen minutes, and dissolving in it as it cools 2 ozs. of softsoap, straining, and adding boiling water to make 1 gallon, as some liquid is lost in boiling. Affected shoots should be gently rubbed between the fingers, well moistened with the preparation, so as to dislodge the pests on the under side of the leaves, then apply the liquid at a temperature of about 100° by means of a spraying apparatus, which insures better distribution, and 1 gallon will go as far as 6 gallons by ordinary syringing. Look carefully over the trees for grubs. One kind, a species of Tortrix, rolls itself up in the leaves, and can be eradicated by squeezing between the thumb and finger; but the other becomes encased on the under side of the leaves, giving the appearance of being scalded, and from the leaves it passes to the Cherries, eating and spoiling them. The only remedy is to search for and destroy the grubs. Supply water or liquid manure to the border as required, keeping trees in pots well supplied, and afford top-dressings of rich material. Pinch side growths at the fourth or fifth leaf, heeling-in extension or side growths required to cover vacant space.

Cucumbers.—Light and sun heat increase the evaporation, necessitating a greater supply of atmospheric moisture, therefore damp the house twice a day and syringe the plants lightly early on bright afternoons. On cold nights 65° is ample, but on mild nights allow 5° more, maintaining 70° to 75° by day and 80° to 85° or 90° from sun heat, closing early so as to increase the heat to 90° or even 100°. Afford liquid manure once or twice a week, with an occasional application of nitrate of soda, $\frac{1}{2}$ oz. to a gallon of water. This puts vigour into the plants and both size and colour into the fruit. Stop the shoots one joint beyond the show for fruit. Thin the Cucumbers well to secure fine specimens, removing superfluous growth, tendrils, bad leaves, and male blossoms. Ventilate early and carefully, avoiding draughts and depressions of temperature.

Plants in Pits and Frames.—These have had a fairly good time, the temperature being kept up without difficulty. Cover the lights at night and prepare material for fresh beds and for linings, sowing seeds as occasional plants are required. (See Melons.)

Figs.—*Earliest Forced Trees in Pots.*—The first swelling of the fruits on trees started in November will soon be completed. They remain stationary for some time in the process of flowering, and as this is the most critical time in their culture every care must be taken to avoid a check. Insufficient moisture or excessive fire heat will cause the fruits to drop when they should be commencing their last swelling, therefore keep the temperature steady. If mild it may be kept at 60° to 65° at night, but if the weather is cold 5° less is safer, and what is lost at night may be gained in the daytime by closing with plenty of heat and moisture (but not with the latter hanging on the fruit), when a rise of 10° to 15° may be indulged in without producing a weak or elongated growth, keeping the temperature through the day with gleams of sun at 70° to 75°, otherwise 65° artificially. Afford copious syringings on all favourable occasions as a means of keeping down red spider. It is prone to attack foliage most in close proximity to hot-water pipes, and should be prevented spreading by sponging the leaves carefully with a soapy solution, 2 ozs. of softsoap to a gallon of water. To encourage the swelling of the fruit top-dressings of rich materials should be applied to the surface of the pots. Supply tepid liquid manure steadily to the roots, giving it in sufficient quantity to pass through the pots. Avoid crowding the growths, stopping at about the fifth leaf, tying out the shoots as the growth advances, and cutting out superfluous shoots. These, however, are best prevented by rubbing them off early, so as to give those left all the light possible. The fruit, to have colour and high flavour, must have full exposure to light and a circulation of warm rather dry air.

Planted-out Fig Trees.—Those started early in the year will require disbudding, removing all the overcrowded shoots, and where there is not room for laying in a long shoot, yet space for some growth, the shoots may be pinched at the fifth or sixth leaf to form well developed so-called spurs for the second crop, the leading and successional shoots, where there is space, being allowed to extend, as these invariably afford the finest fruits and longest succession. Water the border as required with liquid manure, taking care not to apply it too strong, and mulch with an inch of rather rich compost, which attracts the roots to the

surface. Trees in restricted borders, and needing more support, may have roots encouraged from the collar by placing turves interspersed with lime rubbish and manure in contact with it, and by extending the material outwards a quantity of feeders will be secured, which, if duly supplied with liquid manure, will greatly assist the fruit in swelling. Syringe the trees twice a day in favourable weather, damping only on dull days, and keep the mulching moistened as it becomes dry.

Young Trees in Pots.—Shift those intended for next year's forcing, potting firmly, and afford gentle bottom heat. Shade slightly from bright sunshine for a few days until they show signs of having taken to the new soil, when they should be fully exposed to light. Pinch the growths so as to insure a sturdy well-furnished head, training with a single stem of 8 to 12 inches.

Melons.—A ridge about 2 feet wide at the base with the top flattened, so as to give a depth of 10 or 12 inches, is preferable to hillocks, though these may be made about the same in diameter as the width of the ridge, and its depth at the places where the plants are to be put out $2\frac{1}{2}$ to 3 feet apart. The soil should be firm, and when warmed through planting may be done, keeping the seed leaves clear of the soil. The leading shoots should be taken up without stopping until two-thirds the distance is reached they are intended to travel, then pinch out the point of each, and rub off the laterals to the height of the trellis. Some varieties show fruit on the first laterals, and as early fruit is a main feature with the plants allow them to remain, taking out the point at the joint above the fruit at the time of fertilising the blossom. To allow all the laterals to remain would very much overcrowd the foliage, therefore rub off while quite young every alternate one. If the laterals do not show fruit at the second or third joint pinch them at those points, and the succeeding growths will show fruit. Train the growths thinly and regularly, so that every part is equally furnished with foliage, all having due exposure to light.

Melons in Pits and Frames.—Stop the plants at the second leaf before or after planting out. This causes two shoots to push, and these in turn being pinched similarly will give four shoots, two to be taken to the front and two to the back of the frame. Other growths that appear near the collar of the plants should be rubbed off while quite young, not encouraging any laterals nearer the stem than 6 inches, as it is necessary to keep the collar clear. Stop the principal shoots when within 1 foot of the sides of the pit or frame, thus throwing vigour into the laterals, and the growths must not be crowded. The laterals will show fruit at the second or third joint, and they should be pinched one joint beyond the fruit, but not until the blossom is fertilised. Little water will be required, nevertheless maintain the soil in a moist state, but avoid a saturated condition. Cover the lights with double mats at night, and see that the linings are regularly attended to, renewing as required. Prepare material for fresh beds and linings. Three parts Oak, Spanish Chestnut, or Beech leaves, and one part stable litter make the best beds, mixing the materials about a fortnight before it is desired to make the beds. In a few days it will be seen whether there is enough moisture to insure fermentation—if not turn the whole, and sprinkle with water or liquid manure so as to moisten the mass, and when in good heat turn the heap outside to inside, two or three turnings being required at intervals of about four days. Maintain the bottom heat at 85° to 90°, taking care, however, to prevent overheating.

Melon Houses.—In these more moisture is necessary, therefore sprinkle the paths and walls in the morning and early in the afternoon. Ventilate carefully, avoiding cold currents of air, placing some hexagon netting or coarse scrim canvas over the ventilators when the outside air is sharp. Maintain a night temperature of 65°, and the day heat at 70° to 75°, rising to 80°, 85°, or 90° from sun heat, and closing early, so as to raise to 90° or more, keeping the bottom heat steady at 80°. Sow seed for raising young plants to sustain the succession, and shift seedlings into large pots, or add soil as the plants advance. Stop those at the second leaf for frames, but not for trellises.

THE KITCHEN GARDEN.

Globe Artichokes.—The mildness of the weather has started these into active growth somewhat earlier than usual, and there ought to be no delay in removing protective material from the crowns. Where young growths are numerous, these should be freely thinned, three or four strong flowering stems giving better results than a greater number of weakly ones. After the thinning is done give the plants a heavy dressing of half-decayed manure. A soaking of moderately strong liquid manure would not be wasted on the older clumps. It is large succulent flower heads that are required, and these starvelings never produce. A row or rows of the oldest or nearly worn-out plants ought to be destroyed, and a corresponding number of young ones be planted annually. April is a good time to do this, and the requisite number of sucker growths should be saved on the clumps when the thinning out is done.

Jerusalem Artichokes.—It is a mistake to leave these to grow of their own accord on the same plot of ground year after year. Much better results attend the practice of changing the sites, and planting every season. Prepare the ground as for Potatoes, manuring moderately and cultivating deeply. Select medium-sized tubers, planting these whole and before they have lost their first strong sprout. Open drills 5 inches deep and 3 feet apart, disposing the sets 1 foot apart in these. Level the soil, keep the ground free of weeds, and mould up the stems. The white-skinned variety is the best in every way. Dig over the old quarters for all the tubers left in them, rub off the shoots, and store in a heap, soiling over for present use.

Brussels Sprouts.—Since the introduction of more reliable varieties, there has been less need to sow the seed and plant so early as of old, but the heaviest and best crops are usually produced by plants raised and put out comparatively early. Sow seed now thinly in boxes, placing it in gentle heat to germinate, or the requisite number of plants may be raised on a shallow hothed with or without a covering of glass. Market growers sow their seed quite in the open, roughly protecting with straw, and those private gardeners who have little frame or house room to spare should adopt the same practice.

Broccoli.—Early autumn varieties, notably Veitch's Autumn Protecting, can be had in close succession to Autumn Giant Cauliflowers, and the crop may be considered an important one. Seed should be sown now, much as advised in the case of Brussels Sprouts. None of the winter Broccoli should be sown yet. April and May is quite soon enough to sow these.

Leeks.—For the main crop sow seed of Ayton Castle, Musselburgh, or other approved variety on free working soil in the open. Seeing that the plants will most probably be moved direct to where they are to grow to their full size, the seed should be sown thinly, and either broadcast or in shallow drills 6 inches apart. If the ground now occupied by Leeks is wanted for other crops, they may be lifted and laid in closely on a cool border, taking care to well cover the blanched portion of stems with soil. This will also retard bolting or running to seed.

Onions.—Early sowing is desirable, but should not be attempted till the ground is sufficiently dry to admit of its being trampled heavily without binding badly. This important crop ought to have a well-prepared site, the ground if at all clayey requiring to be heavily manured, and deeply dug early enough for the frosts to assist in fining it down thoroughly. Some few naturally free-working soils may be dug, and the seeds sown at once in preference to leaving them long enough to become hard and difficult to fine down. In any case level the surface, making it as fine as possible, also stirring in soot at the rate of 1 peck to the square rod, following with a heavy trampling and a good raking. Shallow but not very narrow drills may be drawn at 10 inches to 12 inches apart, and the seed sown thinly in these. Fix the seed in the drills with the foot, and then give a final raking, leaving all level and smooth.

Autumn-sown Onions.—These can be transplanted now. They ought to have well-prepared ground, but should not share the same site as the more valuable spring-sown crops owing to the liability of the Tripoli section in particular to become mildewed, the wind spreading the disease to other Onions near. Arrange them 6 inches apart in rows not less than 12 inches asunder. Plant at the same depth as they were in the seed bed, and spread out the roots, covering firmly with good fine soil.

Scallions.—Thanks to the roots being so thoroughly harvested last season they are keeping sound, better than is often the case in mild winters. Where, however, they were stored in warm darkened sheds they are softening and forming top growth, and unless attended to will soon be worthless. Plant the greater portion of them in the open ground, about 5 inches asunder in rows 8 inches apart. When strong top growth has been formed draw the Onions as required for use, pulling them to pieces and clearing of old skins. They will be scarcely distinguishable from Tripoli Onions, and will be found of good service at a time when home-grown Onions are scarce.

Rhubarb.—Growth has commenced early on the roots not covered in any way, and there ought to be no further delay in forming fresh plantations. Large, spreading, old clumps are the best to divide, each portion having one or more crowns and a few roots attached. Replant in heavily manured, deeply dug ground 2 feet apart each way if they are to be prepared for lifting and forcing, and 3 feet apart if large strong clumps are to form. Only just the crown should show above the soil, and the soil ought to be made firm about the roots. Mulch with strawy manure, and on no account pull any of the leaves during the first season.

PLANT HOUSES.

Fittonias.—In 2-inch pots these are useful little plants for various forms of decoration. They root readily at almost any season of the year, and may be inserted in the pots in which they are to be grown, and few dwarf plants are more effective when associated with small Ferns or Selaginellas. The two varieties, arranged together as a front margin to the stove or Orchid house, are very pleasing, and the close moist atmosphere of the latter suits them admirably. They are more beautiful when grown in low Orchid pans 4 inches across than when employed in ordinary pots. When arranged at the front of a group of plants these low pans can be tilted so that the plants with their finely marked leaves reach to the base.

Sonerilas.—These are not so useful on the whole as Fittonias, nevertheless where choice plants are grown and appreciated for their chaste beauty a few of these should be included. A few pans in the stove or in the Orchid house are certainly an attraction. These plants grow very well in small baskets in close moist shaded houses. For this purpose the cuttings should be inserted in pans and the plants subsequently dibbled in the baskets, using as a compost rough peat moss and sand. If dewed over twice daily after they are rooted and placed in the baskets they soon cover the material in which they are grown.

Bertolonias.—A stove scarcely seems furnished without a few of these foliage plants. Young plants that have passed the winter well in small pots may be placed into 4-inch, which are large enough for them to develop beautiful leaves. Side shoots on larger plants that were retained, if inserted in small pots in moss and sand, will root quickly in the propagating frame. The atmosphere of the stove is too airy and

dry as a rule for these plants, and until they are developed we grow them in hand-lights in the house.

Panicum variegatum.—For many forms of decoration the old Panicum is invaluable. Associated with Selaginella cæsia, it is unquestionably the best edging to the stove, or any warm house, that can be employed. Those rooted in autumn, and now in 60's, may be placed in 5-inch pots, and before the end of the season the growths will hang from the stage to the ground. Cuttings may be also inserted in 5-inch pots. This plant is suitable for baskets, and in a few months these have a very attractive appearance.

Nepenthes.—Plants that have grown tall should be cut down to within 6 inches of the base. The stem may be cut into lengths of two leaves to each; these if inserted in sphagnum moss and sand, and plunged in brisk heat in the propagating frame, will soon root. Plants which have made four or five leaves, and are not required for stock, may be pinched; this insures their breaking and pitching freely. If they are allowed to "run away" they soon cease to produce pitchers. When the plants are grown in baskets and need larger ones it is the best plan to place the old baskets inside the new, and then fill in with rough peat, lumps of charcoal, and sphagnum moss. These plants are subject to thrips, and the best method of eradicating them is to tie the basket in a piece of close tiffany, and then syringe thoroughly over a tank containing a solution of tobacco water. If the basket is not covered the thrips drop into the moss, and are not long before they establish themselves on the plants again.

THE BEE-KEEPER.

QUESTIONS ON BEE-KEEPING.

ON June 8th, 1895, a stray swarm of bees came and settled on a tree near my cottage, which I hived in a box. Having obtained a bar-frame hive, containing twelve frames, from a neighbour, the bees were placed in it the same night. In the autumn I removed two frames, and left the remaining ten for the winter (No. 1).

On the 13th May, 1896, a strong swarm came off, weighing 6 lbs. This was hived in a straw skep, and in the evening transferred to a double twelve-frame hive (No. 2).

On the 25th May No. 1 swarmed again, the weight of bees being much less than the former, only weighing 2½ lbs. The bees were placed in a small hive (No. 3). In the autumn eight frames containing brood and honey were left in each hive.

On examining them to-day (February 18th) I found them all in good condition; plenty of bees and ample stores. This season I am anxious to obtain one swarm and no more.

Which of the above stocks would be best for me to obtain a swarm from? How am I to prevent the others swarming? When is the proper time to give more empty frames so as to obtain a good surplus of honey?

I shall be grateful for any information "An English Bee-keeper" can give me on the subject, as I know nothing about queen cells and rearing young queens.

During the past season I obtained about 40 lbs. of honey, and was awarded second prize at our local show for a frame of comb honey weighing 5 lbs.—D. H. B.

BEE SWARMING.

As the queen in No. 2 hive will now be three years old, the colony must be requeened at the earliest possible date. This, however, should not be attempted until there are numerous drones on the wing, or it will end in failure. Allow this stock to swarm, the old queen will accompany the swarm, place them in a frame hive on not more than eight frames. The queen being old her laying powers will be on the wane, and probably not a third of the number of eggs will be laid as a young fertile queen would have done. If honey is coming in freely place a crate of sections on the top of the frames, and the bees will at once store a surplus.

Six days afterwards carefully examine the interior of No. 2 hive. Lift each frame out of the hive, and remove with the point of a knife all the queen cells but two. These should be left on separate frames, and are easily distinguished, as they are similar in size and shape to an acorn, point downwards. This being a double hive, place half the frames, brood, and bees on each side of the division board with a frame containing a queen cell in the middle of each. This operation may be carried out with separate hives, care being taken that sufficient bees are placed in each to cover the brood.

In about ten days from the time the stock swarmed the young queens will have hatched out, and if the weather is bright will become fertilised and laying within a fortnight. When this has taken place go to the hive containing the swarm and lift the frames out until the queen is found, which is easily done at that season if the middle of a fine day is chosen for the operation, as the majority of adult bees will be on the wing. Destroy the queen when found, cover the frames temporarily, and return to No. 2

hive. Remove the quilt from one of the divisions, lift the frames out one by one until the queen is found, then take the frame with the young queen and adhering bees and place them in the centre of the brood nest of the hive from which the aged queen had previously been removed.

Place the frames in their original position, and cover up as before. Do not disturb them for a few days and all will be well, no fighting will take place, and the colony will be headed by a young fertile queen. The remaining frames of brood and bees must now be transferred to the other side of the division board in No. 2 hive. These should be placed alternately with the others containing the young queen; they will then settle down as one happy family, and will be of sufficient strength to store a surplus in either shallow frames or sections.

HOW TO PREVENT SWARMING.

Once I found this a very difficult matter, and I know of nothing more annoying to a bee-keeper than just when his bees ought to be settling down to their work to have the swarming mania instead; but by studying their ways and requirements I have proved without doubt that it may be prevented. The chief thing to bear in mind is to rely on young queens as far as it is possible, and to provide the necessary room in the brood nests as well as in supers at the right time.

It is useless giving the bees extra space several days after they have made preparations for swarming. Many people imagine that it is a sudden impulse on the part of the queen when swarming takes place, whereas preparations have been made in the hive for a week or ten days previously, queen cells having been formed, which is a sure sign that the bees will swarm in a few days provided the weather is suitable.

To prevent this give extra frames once or twice a week as fast as the bees can cover them, and when the brood nest is showing signs of being crowded place a super on the top, either sections, shallow frames, or full-sized frames, as advised in previous notes.

GIVING EMPTY FRAMES TO OBTAIN A SURPLUS.

This will depend on the time of the honey flow. If from the fruit tree blossoms special precautions will be necessary by restricting the size of the brood nest so as to encourage the bees to store a surplus in supers; afterwards, if "D. H. B." is situated in a good White Clover district, extra frames may be provided for the queen. It is only in exceptional instances that it is necessary to reduce the brood nest early in the season, as it has a tendency to cause swarming.

If the advice is carried out as given above, all that will be necessary afterwards will be to place more empty frames or sections under those partially filled, and to remove those that are quite full when ready.

If "D. H. B." would like any further information he must write again. Had he left an extra space between the frames when working for extracted honey, the cells would have been deeper, and the frame of well-sealed honey (standard size) would have weighed about 8 lbs.

FEEDING STOCKS WITH CANDIED HONEY.

"I HAVE a quantity of candied honey. Can I feed my stocks with it? If so, will you kindly inform me how I ought to proceed? My hives are bar-frame, and extra straw skeps with flat tops.—J. G.

Candied honey may be made liquid by placing the vessel containing it in hot-water. Unless the bees are short of stores it is not advisable to feed them with liquid food so early in the season; a bottle feeder should be used, there will then be no escape of heat from the brood nest. The honey should be given to them warm in the evening, and well covered up. An ordinary broad-necked honey jar covered with a piece of tiffany or muslin will make an excellent feeder, and if some perforated zinc is placed on the top of the frames the bees will not be disturbed during the refilling of the feeder. This is all that is necessary on the top of straw skeps; a flower pot slightly larger than the feeder, and placed over it, will prevent it being damaged.

The entrances of all hives that are being fed with honey must be reduced, or robbers will gain an entrance and play havoc with the stores.—AN ENGLISH BEE-KEEPER.

* * All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Victoria Regia (E. T. H.).—We do not remember a small inexpensive book which gives a description of this remarkable plant, which has been illustrated in the *Journal of Horticulture*. Possibly some of our readers may be able to supply the information you require.

Definition of "Cottager" as an Exhibitor of Garden Produce (G. Hambow).—A rigid definition applicable to all districts and shows is a practical impossibility. We have consulted a very experienced horticulturist on this subject—we think he has been a cottager, we know he has been a gardener and judge, and he now comes within the category of amateur. He has given much thought to the matter, and expresses his views as follows:—"A 'cottager' may be defined as a person occupying a house at a rental of not exceeding £10 in the country or £20 in or near towns. He may have a garden or an allotment, or both, and must do all the labour in connection with the production of plants, flowers, fruits, and vegetables with his own hands, in addition to the work by which he obtains a livelihood, as a person working for wages day by day, week by week, and year by year. Thus the term 'cottager' includes every class of workman, classed as labourer or artisan, and restricts it absolutely to a person working for an employer during ten hours (or about) of each working day in a year, and who does not employ (illness excepted) any person to do any part of the work in his garden or on his allotment, except his wife and members of his own family not exceeding fourteen years of age. This is very simple, and excludes master tradesmen, pensioners, policemen, and others who can give attention personally to greenhouse plants, gardens, or allotments for several hours in the daytime. Thus the line is drawn hard and sharp between a 'cottager,' who does a day's work for a master and has no time to devote to the cultivation of plants, flowers, fruits, or vegetables, except between 6 P.M. and 6 A.M., and an 'amateur,' who, though not occupying a higher rented house or a large area of land, does the main of the cultural operations in connection therewith in the daytime, and in that respect has a manifest advantage over a person working for wages and doing all such operations in his leisure hours, whether growing in that time for his own use solely or for disposing of surplus produce. Under those conditions a 'cottager' may grow as many window plants as he has accommodation for, and supplement them to whatever extent his pocket allows by means of a greenhouse. Likewise as regards flowers, fruits, and vegetables, no limit need be placed on the extent of garden or allotment, for one person will manage twice as much as another, as a great deal depends upon 'brains,' industrial energy, and perseverance, the chief object being to encourage the 'cottager'—a person working for wages—to employ his leisure hours to the best advantage to himself, his family, and country. That is a broad view of the case, and secures the 'cottager' justice at exhibitions. But there are generally particular objects in view by different horticultural societies in offering prizes, hence certain restrictions are imposed in both rural and urban districts. In the country a 'cottager' is usually confined, as regards 'glass,' to window plants; and in respect of garden or allotment, to the extent apportioned generally to each individual in the locality and within the district embraced by the society. In urban districts similar remarks apply, no 'cottager' being allowed to exhibit plants grown in a greenhouse except in a class for such plants, for if a person so growing them exhibit in a window plant class the whole thing is a delusion, and an injustice to a *bonâ fide* exhibitor of window-grown plants in strict accordance with the schedule. In the narrow sense, therefore, the definition of a 'cottager' is a matter for the committee of each district society to determine, and the decision should be clearly stated in the schedule, also strictly enforced by the officials of the society, not by the judges." The above observations cover the ground of your questions. As a matter of practice, we know that in some schedules classes are provided for such persons as policemen and postmen, who, though living in cottages, have many hours in the daytime for working in their gardens, which ordinary day labourers and other workmen have not, and these only are regarded as genuine cottagers.

Fish Offal (Inquirer).—The best practice is to dry and grind it, forming "fish meal"—a fine powder in excellent condition for use. With an equal amount by weight of kainit added to it, it forms an effective manure, especially for light soils, and one of the best for garden crops generally. As you may not be able to dry and grind the fish offal it may be formed into a compost, preferably by adding as much dry wood ashes to it as its bulk, and covering with gypsum in an outhouse, leaving until decomposed, dry, and crumbling, then mix all together, and use at the rate of about 8 ozs. per square yard: If you cannot procure the wood ashes mix with two parts soil, as much kainit as weight of fish offal, and form into a heap, with an addition of half as much gypsum as fish refuse placed outside, or cover with soil. When decayed it forms an excellent manure, using about 1½ lb. per square yard. If there be any smell sprinkle powdered sulphate of iron over the heap, not using more than 1 lb. to each 100 lbs. of fish offal. It is better, however, to mix it with the compost, then cover with earth or gypsum.

Narcissi After Forcing (M.).—The several varieties of Narcissus incomparabilis, also double and single Daffodils, are of further use after they have been forced, provided the leaves are grown and ripened under favourable conditions, and thus store matter in the bulbs. This may be effected by keeping the plants in a cool house, or even pits or frames, with protection in severe weather, so as to inure them to a lower temperature and enable them to bear the external air; then they may be planted outdoors, or kept in the pots or boxes until died down, not allowing them to suffer by lack of water, nor overdoing it. In July the bulbs should be lifted or shaken out of the pots or boxes, and planted in beds of well-prepared loamy soil, preferably rather strong, planting in rows 6 inches apart, and the bulbs 2 inches asunder in the rows, and that depth. With a mulch of any rich material in autumn keeping clear of weeds, and giving a liquid application of manure about the usual time of flowering in spring the plants will come round in two or three years, usually two, and then may be forced again. They are lifted in July, the strong bulbs kept for forcing, and the smaller planted to maintain a supply for the same purpose.

Magnolia Leaves Brownd (A. L. M.).—We cannot detect any fungoid or other organism likely to cause the discolouration in the leaves. It has been caused by a sudden check, such as the arresting of evaporation from the leaves by a thick covering of hay or similar material, the respiration being practically prevented, and the moisture in consequence remaining in the tissues, thus "sweating" and the parts dying. We find that similar cases have occurred in young trees imported from the Continent, through their having been thickly wrapped in hay and matted to safeguard them against injury in transit. The young wood of Fig trees also suffers in a similar manner when very heavily covered with hay or short straw, evaporation being prevented and the moisture kept constantly on the tender young wood surface, hence the destruction of the epidermal cells, as evidenced by the browning. The leaves, as shown by the green parts, were quite healthy before being deprived of evaporative power by the covering, and the parts remaining green are so because either more developed towards maturation in tissue or from the covering fitting less tightly over the parts. If the wood be browned as well as the leaves it may be advisable to remove the tree and replace it by a healthy one, or the present tree might push good growth if cut back to firm wood. There is no need to cover this very desirable wall tree very thickly to insure its safety from frost, a little loose material placed amongst the growths and a covering of mats to keep it in place being ample. Then the tree will receive plenty of air and even some light, retaining the foliage in a green healthy state.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (A. H.).—Court of Wick. (J. S. U.).—The Pear resembles Figue de Naples. The Apple is not recognisable, but it is not Cox's Orange Pippin.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (H. Stapley).—1, *Acacia longifolia*; 2, *Oxalis*, flowers closed and withered, perhaps *O. Bowei*; 3, *Leschenaultia biloba*; 4, *Pimelea spectabilis*; 5, *Fuchsia procumbens*. (Young Hand).—*Cornus mas*.

TWO PARASITES.

WHAT is a parasite? Well, we all know a parasite is more or less injurious, but how can we define it accurately? A parasite is simply "an organism which obtains food and lodging on or in another organism higher in the scale of life than itself." These exist both in the animal and vegetable world, and examples are so all around us that everyone can suggest cases for himself. Curiously enough the living organism of the animal kingdom is liable to attacks from a vegetable organism, and *vice versa*. Sometimes these visitors do little or no harm to their hosts; in other cases they repay the debt they owe with interest by causing severe suffering and even death.

We purpose in this article to deal with two of these pests, the one more especially affecting the health and well-being of calves and yearling stock, the other attacking the mature cattle.

We will take first ringworm, which we find prevalent mostly in calves, horses, and man; dogs also are sometimes affected, sheep and pigs rarely. It is curious, too, that this complaint should prefer young stock; seldom, or never, does a case occur on stock

over two years old. Ringworm, too, has its limits of being—that is, the disease will die out of itself without active measures being taken for its suppression, but it seems a folly and waste of time in this case to let Nature work her own cure when she takes from six weeks to three or four months to do it in. Not only is the animal losing condition during that time, but also it becomes a grand centre of infection.

A calf in a thriving condition, well fed and well cared for, will soon throw off the disease. A weak sickly calf, on the other hand, seems to give the complaint every encouragement; the disease does not die out of itself, and remedies fail to make any impression. This parasitic fungus attacks the hair of the patient, and sets up an irritation of the skin which must affect the nervous and nutritive functions.

The skin becomes rough, and is covered with pimples, which in drying and dying become scurf. This scurf and the hairs are found covered with spores or seeds of the fungus, which readily germinate and grow under favourable conditions.

Ringworm is exceedingly infectious, and exceedingly hard to get rid of. Cases have been authenticated where spore has remained some months on tree bark in winter, and then being placed in a cultivative media has grown in the usual manner. A temperature below freezing point does not affect the fertility, whilst warmth and moisture favour the growth of the spore.

When we consider how spores may be thus disseminated by the diseased animal rubbing itself against trees, posts, and the like; how it may be disseminated by the droppings of impregnated scurf, and carried on the bodies of lice, there is little wonder that ringworm is so prevalent. With care, however, this infection can be dealt with, but the matter must be taken seriously in hand, not treated in a haphazard way. Manure and litter should either be burned or ploughed in. After the floors of sheds, posts, and pillars have been treated to a wash of some disinfecting fluid, then must come the inevitable lime.

Where infested calves have been on grass a dressing of lime may be used with good result. Mouldy old sheds, rotten wood, decayed vegetable matter, all prove most excellent hotbeds for propagating the seeds, and a little trouble should be taken to remove such obvious causes of danger. As to the treatment of the animal opinions differ; whatever dressing be applied should be applied thoroughly. The scurfy crust of the scab should either be washed or currycombed off, so as to allow the curative agent free access to the fungus in the deeper tissues. Need we say that all this extraneous matter must be carefully removed and burned?

Sulphuric acid with glycerine is very effectual, and should be put on with a brush. To keep the rest of the body free from attack a dressing of vaseline will be found most serviceable.

Warble or bot fly is a trouble that is easily combatted, and it seems a great pity that farmers should be so apathetic in their efforts to remove this pest, which does so much to irritate the genus "Bos," causing cattle to be ever on the move, tearing and raging about, doing infinite harm to the milk supply, the immature beef, and, above all, to unborn calves.

We talk about the placid, ruminating cow, but how can she be placid or ruminate stung to madness by the attacks of this wretched fly? The female fly begins to lay her eggs as early as May. Maggots have been found in November on the flesh side of the hide; they are provided with a fine channel up through the hide. As the maggot grows it assumes a club-shaped appearance. The tail is at the opening in the skin, and through the tail it breathes. The mouth is downwards, and feeds on ulcerated matter caused by its perpetual suction on the flesh of the ox.

The maggot must breathe, and so, therefore, any application to the tail end will have the effect of choking the breathing apparatus, or running down into the hole will poison the maggot. Get rid of the maggot the beast grazes in comfort, and the wound has a chance of healing. The maggot leaves the warble hole itself when full grown—that is to say, about 1 inch long. Hidden on the

ground it changes to a chrysalis, and from that chrysalis emerges the warble fly, and the mischief begins again.

The maggots may, of course, be squeezed out of the hide, but a little dressing or dip put on the aperture of the warble hole is equally effectual. Grease of any sort mixed with sulphur and tar can be used without any risk. Mercurial ointment requires careful handling, and should only be put into careful hands. Prevention being better than cure, a dressing of train oil, sulphur, and spirits of tar rubbed on the spine, loin, and ribs will keep off any attack by the fly. It is a curious fact that the flies will not pursue cattle over water, nor are they so abundant where there is a little shade to be found.

Not only is damage done to stock by the constant irritation, but the hide, in itself a valuable commodity, is spoiled by the actual holes left in it, and by the weak places that have only partially got skinned once. Miss Ormerod, who is a great authority on this question, says that in one year out of 102,877 hides examined 60,000 were found greatly injured by the ravages of this fly.

If the maggot be destroyed before it gets a chance of leaving its home in the skin of the bullock, the chances of warble fly in another season are practically done away with. It has been estimated that the annual loss occasioned by this one parasite is not less than £2,000,000, and possibly far exceeds that sum.

WORK ON THE HOME FARM.

A few fine days have worked wonders to the land, the Cambridge roll is at work on the Wheat, and doubtless here and there the drill also.

The question, "What to sow?" is exercising many minds. Prices of spring corn have been very disappointing, both Barley and Oats being now much lower in price than was expected; whilst, though Wheat may be included in the same category, yet the future prospect in its case is much brighter than in the cases of the other two, the world's Wheat supply for next year being very unlikely to be an excessive one. There is, therefore, good encouragement to farmers to sow a little spring Wheat, but it must be put in at once; medium to light soils are most suitable, and white Wheat is the best to sow. There is no better Wheat than Hunter's White for this purpose.

On good soil, the sooner Oats are in the better. We have had great satisfaction from a white variety named Catterick Hero; it is a very heavy cropper, with beautifully fine straw, stands better than any, and the quality is first-class, which may be realised when we say it is a favourite for racing stable use. We think this Oat and the Black Tartarian the only varieties a farmer need want.

The cross-cutting of fallows must be attended to at once, and the drag and harrow will shortly have their turn; light lands are already in fair working trim, and no time must be lost in giving them at least one dressing, as we do not know what or how few chances we may have later on. A crop of Twitch got off now is as good as two in May. "A stitch in time" is a proverb exceedingly applicable to the cleaning of land.

Young seeds are making a welcome move, and some fields are showing quite a nice bite. The woodpigeons, however, having eaten all the Turnip tops available, are now paying special attention to the young Clover, and very injurious is the result. We are having organised raids on these birds, every available gun being brought into requisition on Wednesday afternoons to await their arrival in the woods when they come home to perch. A large number may be killed in this way if each gun gets but three or four, and we commend the system to other districts where woodpigeons abound.

REMARKS.

- 21st.—Bright sunshine almost throughout.
 22nd.—Mild, with much bright sun in morning.
 23rd.—Fine, with frequent bright sunshine.
 24th.—Fine and mild, with a gleam of sun at 4 P.M.
 25th.—Overcast, with high wind throughout.
 26th.—Mild and generally sunny.
 27th.—Sunny throughout.

A dry week, remarkable also for uniformly high temperature.—G. J. SYMONS.

BARR'S EARLY DWARF "BEST OF ALL" CAULIFLOWER.

Remarkably early, dwarf and compact, with heads as white as snow.

Per Packet, 1s. 6d. and 2s. 6d.

BARR'S CHAMPION SOLID WHITE CELERY.

Very solid and sweet, remaining longer in condition than any other White Celery.

Per Packet, 1s. and 2s. 6d.

BARR'S NEW THICK-FLESHED TOMATO.

Surpasses all other Tomatoes in depth of fruit, solidity of flesh, high quality, and heavy cropping.

Per Packet, 1s.

BARR'S SPECIALTIES IN FLOWER SEEDS FOR 1897.

BARR'S SUPERB MIXTURE OF GLOXINIAS.

Seed saved from a selection of the finest named varieties. Certain to please. Per Packet, 1s. 6d., 2s. 6d., and 3s. 6d.

BARR'S EXTRA SELECTED LONG-SPURRED COLUMBINES.

A very choice mixture. Flowers of great beauty in form and colour. Per Packet, 2s. 6d.

TREE LUPINS, mixed, saved at the "LONG DITTON" Nurseries from 10 beautiful delicate shades. Per Packet, 1s.

BARR'S NEW SEED GUIDE FOR 1897

will be sent free on application.

BARR & SONS, 12 & 13, KING STREET, COVENT GARDEN, LONDON.
Nurseries at LONG DITTON, Surrey, near to Surbiton Stn., S.W.R.

ANT. ROOZEN & SON'S

CHOICE VEGETABLE & FLOWER Seeds

FOR PRESENT SOWING,

AND

BULBS AND PLANTS

FOR SPRING PLANTING.

COLLECTIONS OF VEGETABLE AND FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM, HOLLAND, or to our General Agents,

NEW AND DELICIOUS MARROWFAT PEAS.

Copyright [J. C. & Co.]
A POD OF
CARTERS' EARLY MORN.

As introducers of the famous Stratagem, Telephone, Daisy, and Telegraph Peas, we invite a trial of the following New Varieties, all of which represent the most advanced types in the different sections for Garden Use, and will make their mark.

CARTERS' SPRINGTIDE.

A first early wrinkled Pea, as early as the smaller-podded round-seeded varieties, with the delicious flavour of the Marrowfat. Height, 2½ feet.

In Sealed Packets, 2s. 6d. per pint; 4s. per quart, post free.

CARTERS' EARLY MORN.

Another fine Marrowfat, with very long pods, a good colour, and well filled, almost as early as our Springtide. Height, 2½ feet. Stock very limited.

In Sealed Packets, 2s. 6d. per half-pint, post free.

CARTERS' ST. OSYTH GEM.

A cross between Chelsea Gem and Stratagem, combining the best points of both these excellent kinds. Very early. Height, 1½ feet.

In Sealed Packets, 3s. 6d. per half-pint, post free.

CARTERS' SEEDLING.

A New Maincrop Marrow, the result of crossing and interbreeding from the three popular varieties, Stratagem, Queen, and Autocrat. Its pods are amongst the largest we have ever seen, and we have counted as many as thirteen Peas in a pod. Height, 3 feet.

In Sealed Packets, 3s. 6d. per half-pint, post free.

CARTERS' DAISY

Is a New Marrowfat Pea that embodies the best features of an ideal variety—viz., earliness, habit, size of pod, and delicious flavour. Carters' Daisy is not a selection, but creates a distinct break in Marrowfat Peas. Its merits have received recognition from the Royal Horticultural Society on more than one occasion. Dr. Masters, F.R.S., inspected our crop, and illustrated this remarkable Pea in the columns of the *Gardeners' Chronicle*. Height, about 1½ feet.

New Hand-picked Seed in Sealed Packets, price 2s. per pint, 3s. 6d. per quart, carriage free.

Illustrated CATALOGUE, Gratis and Post Free.

Journal of Horticulture.

THURSDAY, MARCH 11, 1897.

FADS ABOUT FRUIT.

ON another page an alert correspondent, who likes to be up to date, if not a little in advance of it, appears to have been enjoying himself in distinguished company, and seems to have detected some "axe grinders." That is not very remarkable; they are so plentiful that we can find them almost everywhere. They are excellent men too, many of them, and not a few have done a considerable amount of good.

The occasion was the reading by Mr. George Gordon of a paper on orchards at a meeting of the Society of Arts. Mr. Gordon is a practical man, and nothing would please him better than to see the orchards of this country bearing bountiful supplies of superior fruit. He knows, too, the value of the best varieties of British Apples grown in the best condition, and how far this value exceeds that of the small uneatable varieties grown for cider. This he pointed out in the citation we gave on page 180 last week; but though his object was clear enough, and he pointed out the way to attain it—so far as it could be attained in improving old trees—the discussion seems to have been turned into other directions having little or nothing to do with the art of cultivation as applied to the production of hardy fruit equal to that from distant lands. Why has this imported fruit got such a strong hold of our markets? Because it is the result of the prudent choice of varieties, intelligent cultivation, and business-like methods in the disposal of the produce.

The discoverer of the "axe grinders" at the Society of Arts is not a cider man, and if we are correctly informed he let the meeting know it; also he seems to have been chilled somewhat by the advocacy of cold storage, while he is not likely to lead a crusade in favour of growing fruit in this country for the purpose of having it dried by the process of evaporation, and then having the dissipated moisture made good by soaking before the fruit can be used. He knows something about the drying process as conducted at Chiswick for several weeks; but one thing he does not know—namely, that one penny of profit can be shown as the result of the fairly conducted trials, for no such profit was represented

in the report allowing nothing for the cost of the machine, which was unfortunately a poor one and did us very well.

Then he is dubious as to the practical value of the cold storage system for preserving fruit having regard to its quality after being long subjected to the chilling process. Experiments in this direction have been made under the auspices of the Royal Horticultural Society, and the report of the Committee that was appointed to conduct them was published in one of the Society's journals. This was the reverse of encouraging, and if the experiments proved anything it was the impracticability of the process. Fruit cannot be kept in an artificially made winter for months or years without cost, but its flavor can be easily destroyed, and half the fruit tested in the experiment in question was rendered useless.

It is neither by drying fruit nor freezing it artificially that its value as a product of the soil can be increased in this country to an extent that it is so greatly desired; nor can the planting of under orchards for the production of grain however wholesome, or the rearing of patriarchal orchards of Apples grown for eating raw or cooked raise the standard of the fruit to anything approaching that of the imported produce that is such a weight to our cultivators and consumers. It is desirable that what can be done in improving the fruit of ancient orchard trees for home consumption and local use should be done, and we know that much good has resulted from thinning, cleaning, feeding, and grafting; but not one ancient tree out of a thousand can be made to produce fruit that can hold its own in our markets against the produce of young trees of well-chosen varieties planted in good well-prepared soil and subjected to a routine of sound cultivation.

The only safe and sure course to follow in effecting material improvement in our national fruit supply is in the direction just indicated, and it is to be feared that the parade of counter propositions under a very naive but a tendency to divert the mind of men from the best of all methods—systematic training and cultivation—for securing fruit of the highest excellence and in a certain way or other get so well and give equal satisfaction to growers and consumers.

There were some other points than those of the late Mr. Stanley Rivers with me. The best fruit is the product of cultivated soil and cultivated plants; and it is encouraging to know that the best home-grown Apples of the last season's crop retained a great power that any that reached our markets from abroad. The vast mass of the "best" and they can only be produced by the exercise of sound judgment and intelligent routine methods of cultivation.

Next to the autumn the present is the best time for planting trees of all kinds for profit or ornamental purposes. The swelling of the buds is the first incentive to the immediate production of fresh root fibres. An enormous amount of spring planting is done in parks and gardens, and we were in brisk progress now. The most important point in connection to observe is the taking of special care in keeping the roots moist in transit. If they arrive dry they should be placed in water for some hours or the trees kept wet with root and water, by syringing and covering with damp mats. Then after pouring all broken roots unceremoniously, planting carefully and well, smoothing well back the long, strong branches for retaining the evaporative surface but leaving all the short and smaller ones full length for their terminal buds to develop leaves as soon as possible. The trees will be quickly established. Not improbably some of them may grow quite as well as those planted last autumn and those which do not will have a great advantage next season over those that may be planted at the end of the present year. Let the planting of fruit trees go on; and if old stumps, etc. are to be improved the work, to be satisfactory, must be done under the supervision of experts. Much more harm than good may be done, and has been done, by the hacking of trees by unskilled men without experienced guidance.

DECORATIVE PLANT HOUSES.

In private gardens we look for permanent embellishment of our plant houses by such little aids as so many of the simpler forms of plants are able to give, some of which would otherwise scarcely claim the right of association with the rightful occupants. However that may be, we have a great variety of interesting, suitable, and beautiful objects when thus employed which are especially adapted to this adjunctive purpose, and the eye of taste will not fail to discover abundant opportunities for the deft hand to adorn what may be, and often is, the severely plain, or the purely practical. From the coldest of cool houses to the warmest of tropical ones there are not any but what offer more or less facility for the purpose, but the latter are *par excellence* amenable to this treatment with an additional charm and character.

In all cases, and for various purposes, the virtues of virgin cork commend it for free use. Its comparative cheapness, when taking its durability into account, being a strong feature in its favor. As an edging for the stages in strips of about 4 inches wide, I know of nothing which gives such universal satisfaction, and in those houses where warmth and a corresponding degree of moisture are maintained the simple plan of filling in the interstices—the joints—with bits of our indigenous Fern-like moss, makes a foundation for an edging of verdure particularly pleasing. Common as is this moss, for in our woods it can be gathered by cartloads, one never tires of admiring its beauty, and now in singing its praises the desire to call it by its proper name comes strong upon me, having to confess, with some shame, that it is unknown, hence a sample will accompany this to gratify the editorial eye, and lighten my darkness.

The peculiarity about this moss is that, hardly child of Nature as it is, it fairly revels in the heat and moisture of a tropical house when lovingly clinging to the virgin cork, but on any other foundation it invariably withers or withers and quickly dies. This edging with some little planting, of which moss alone leaves nothing to be desired, with one exception—viz., the or any similar edging provides a harbour for insects and other "pests." However, those who have noticed the vast difference between a bare stage and one so draped will probably think that such small gains are worth the trouble consumed in watching them.

On the broad question of the permanent decoration of our plant houses the wall need only be mentioned. Happy is the man who has a back wall to his house, and happier still if he has an end one too. He has, I am sure, made the best use of such an opportunity, but I may remark in passing that one of if not the best one I have seen made of this situation was that of a tropical house in which the back wall was clothed with three varieties of *Alb.-clay-cactus*—*fulgens*, *Lobbianus*, and another not remembered. These, planted at the base of the wall had climbed to the top, some 12 feet, and thence depended in long streamers massed with brilliant blossoms, and were as useful as ornamental, being much prized when out as trailers for long tramper races. Potted argives it also as cheap wall climber for a hot-house, whilst for those on the largest scale there is no nobler plant than the *Monstera*. Owing I suppose to the subject being not having been something of a novelty it is carrying me further than I am sure is necessary, hence we will return to the stages, where presently an opening exists to insert a few facts.

If whatever material our stages are made, whether of wood, iron or stone, the virgin cork is eligible as an edging. In the two latter cases a substantial lead laid along the margin will provide sufficient foundation for seating on the cork. At one time I used Slater's nails for this purpose, but the flat heads being somewhat conspicuous when rusted, ordinary French wire nails give as good a grip, and are all but invisible. Stages generally being covered with some moisture-holding medium such as fine gravel, breeze, or other material, sea gravel put through a half-inch meshed sieve is clean and bright, and very satisfactory, even but a slight covering will form a foothold for various things used in marginal planting, supposing, of course, that moisture is always retained; yet it can hardly be overlooked that our subject in all its phases is more or less means to that end—the retention of moisture.

Supposing our staging being edged with cork is covered about as much deep with the material mentioned, the labour of planting merely consists in the insertion of small cuttings, rooted ones by preference, just inside of the cork boundary; and from time to time at odd moments stray pieces or seedling Ferns will be comfortably tucked in until the edge of our stages becomes a thing of beauty, and a joy for—say twelve months, then possibly it will have become a little poky. This will at the present season generally be the case, but coming as it does when we are setting our plant houses in order for another round, the shears may be employed to clip the whole concern close into the roots, and our edging will break into fresh beauty almost immediately.

There is one plant which, in its cheerful tone of colour and graceful manner of growth, stands pre-eminent for the purpose, this is *Panicum variegatum*. So far as its foliage is concerned its character is not aggressive, and it forms an admirable setting, setting off rather than hiding out anything else employed. It is so common this *Panicum*, so well known, that one is diffident of further extolling its merits, but they are many, and to those who have not seen it thus grown, gracefully hanging some 2 feet deep from a long length of staging, I would especially commend it to their notice. The white and the red-veined *Futtonias* are charming when established between the joints of the cork, to which they take kindly. One other plant only will I mention here, that is *Pilea muscosa*, the Artillery plant, which grows apace under these conditions, and is in every way admirable for the purpose, and which is too amenable to any restriction if inclined to grow too strong.

Under the stages not an inch of bare space need obtrude itself to catch the eye, provided, of course, that the hot-water pipes do not interfere, and even in this case much may be done by the crudest form of rockwork. According to space and position many things will flourish here, from a carpeting of the common *Lycopod* to handsome *Begonias* of the Rex type. *Panicum plicatum* is a plant more seldom met with than its merits deserve, and if planted in odd corners near the margin of the walks, will often be found useful for cutting, its bold plaited foliage being well adapted for decoration. Where this plant is established seedlings spring up, which, if potted and grown as specimens for house decoration, take on much of the character of *Curculigo recurvata*, for which I have seen it mistaken. That ubiquitous plant *Saxifraga sarmen-tosa* (Mother of Thousands or Hen and Chickens) is as happy, if not happier, under a stage in any temperature as it is in its natural element—the open air, and gives a kind of alpine feature, growing amongst a few rough stones or boulders. The tricoloured leaved variety is a gem when it retains its character.

Our subject is sufficiently comprehensive to include and beautify all the plain features of our plant houses internally at a minimum of expense of either time, labour, or material. In one small stove house a large iron water tank set on the floor supported the central stage. As it monopolised as much space as could well be spared we could not see our way to hide it by even so much as a wood casing, which could again have been covered by cork. It was an eyesore, to me at least: but *Ficus repens*, a plant which, if it ever had a popular name bestowed upon it, should be called the Gardeners' Friend, came to our aid, and a few rooted pieces inserted in the joints of the flooring close up to the tank went onward and upward, covering with delicate tracery the unsightly object until it ceased to offend.—INVICTA.

[* The moss referred to has long been known as *Hypnum proliferum*, or the Proliferous Feather Moss. It is probably the handsomest of our native *Hypna*, of which we have in Britain about seventy described species. This species is common in most shady woods and moist hedgebanks, its fruiting season being November and December. It is known and acknowledged by recent authorities on moss as *Thuidium tamariscinum*.]

DECIDUOUS DENDROBIUMS.

LIKE many other Orchid genera, this favourite genus does not lend itself to collective cultivation exactly, but most of the deciduous species may be grown together under very similar conditions. They are a beautiful class of plant, their colours rich and striking, of exquisite texture, and delightful form. Few things are more pleasing than a well-grown and profusely flowered specimen, say of *D. Pierardi*, its long pendulous stems, wreathed with the soft pink blossoms, having a remarkably fine effect. The showy *D. crassinode* again, when in good condition, finds a host of admirers, any of whom seeing it for the first time will assuredly be lavish with their praise.

Even such pigmy forms as the little *D. Loddigesii*, or *pulehellum* as it is generally known in gardens, have most exquisite flowers, produced moreover in great abundance considering the size of the plants. Similar to these in colour, but totally different in habit, is *D. Devonianum* (fig. 41), a plant worthily named after the founder of one of the most celebrated collections. This produces a perfect shower of bright and telling blossoms, and no collection of *Dendrobiums* can be complete unless this grand species is well represented.

And so one may go on in praise of this section, but possibly most of our readers are more anxious to know how to produce these lovely flowers than to read a dissertation upon their charms.

One of the first necessities for their culture is a well-heated, lighted, and ventilated structure, for from the time the young shoots appear at the base of the flowering stems until the new pseudobulb has attained full size no check of any kind must be allowed. At first these young shoots are rather impatient of sunlight: it is apt to scald them, as the term goes, especially if, through neglect of early morning ventilation, any of the night moisture is still about them. But after they have made a little progress, when the

FIG. 41.—DENDROBIUM DEVONIANUM.

leaves have commenced to unfold and the base of each is getting a little hardened, they will stand with impunity a good deal more sun than most Orchids.

As hinted above, early morning ventilators should never be neglected, in bright weather more especially. Before the sun reaches the house a chink of air should be put on, and this must be increased, and every part of the house thoroughly damped as soon as a slight rise in temperature can be noticed. The atmosphere will then feel buoyant and fresh, and will more nearly approach the conditions that obtain in the native habitat of the plants than would be the case were the ventilators kept close until some stated temperature was reached. If amateur cultivators would use this sense of feeling more, and rely less upon hard and fast rules, hydrometers, thermometers, and other so-called useful aids to Orchid culture, we should hear less complaints as to Orchids being difficult to grow.

Soon after midday—more or less according to the aspect of the house—will be "shutting up time," and the floors, stages, and walls of the house must be thoroughly damped, first taking off the air, and last of all removing the shading. The plants in most cases are better for a sprinkling at the same time, and if by these means the temperature of the house runs up to 90° or even 100° all the better. Growth will be very rapid, yet owing to the amount of light and air received the texture of the forming bulbs will be firm.

The length of time the plants remain in this heat must depend to a great extent upon the species. Some finish up their growth much earlier than others, one of the first being the popular *D. Wardianum*. One of the last may be mentioned—viz., *D. superbum*, which takes a long time to mature its immense stems; but I will cite no more instances, and rather leave readers to observe for themselves the peculiarities of individual kinds. As a rule, as soon as the last leaf is matured slightly drier conditions of the atmosphere are advisable, and in every case the plants, if they have been grown as described, will by this time be better for full exposure to the sun. It is not more important to ripen a Peach shoot thoroughly than it is to ripen the stems of these deciduous *Dendrobiums*. They cannot flower properly without it, and although this matter has been mentioned time after time in the horticultural press, one is always coming across instances of the advice being disregarded.

Quite as important is a thorough rest after ripening, indeed it may almost be described as part of the ripening process. During

this resting season the plants do with very little heat, a minimum of 48° or so being ample, but they must be kept dry. No water should be given unless the stems shrivel, and this is of rare occurrence with the plants described. Then with the lengthening days in spring flowers in plenty will be produced. With regard to receptacles for growing them in, these must of necessity vary with the habit of the species and the quality of the roots and compost. It is, however, generally safer to under rather than over-pot, as the roots in many cases are not ambitious in leaving the centre of growth, but prefer to coil round and round each other, and often in a congenial compost form a dense ball of fibre.—H. R. R.

EELWORM AND TOMATOES.

I AS well as Mr. Bradley (page 118) am desirous of getting some practical information respecting eelworm in soil. I am now erecting a Tomato house 100 feet long on an old pasture which abounds with eelworm. Does Mr. Abbey advise a 10 per cent. lime dressing in this case or what? We have yet to see the result of Mr. Iggulden's experiments and experience with Tomatoes, but I think market growers like myself would prefer rather to destroy the eelworms than rely altogether on good cultivation such as Mr. Iggulden advises in the case of Cucumbers. My experience differs from Mr. Bradley's. I have Tomatoes doing well in soil which six weeks previous to planting had received a 10 per cent. lime dressing, although I am surprised to notice plants in the same soil dying off at the ground level, as shown on page 545, June 11th, 1896. Can Mr. Abbey account for this?—T. P. R.

["T. P. R." does not say whether he intends to use the top 3 inches of the old pasture with its turf as a compost or employ the land *in situ* for growing Tomatoes. If the first, and he can wait six weeks, I should not hesitate to cut the turf, and mix with it 10 per cent. of the best freshly burned chalk lime, slaking, and incorporating along with three-quarters of a pound of best quality kainit, and 3 quarts of fresh dry soot per cubic yard. After lying the time named break up, and place in the bed or border 10 to 12 inches deep, having previously placed in the requisite drainage material, preferably chalk or old mortar rubbish.

Before placing out the Tomato plants apply a dressing of the following mixture:—Fish meal ("white fish"), 10 parts or lbs.; mineral superphosphate (34 to 37 per cent. soluble phosphate), 2½ parts or lbs.; nitrate of soda (95 per cent.), 2½ parts or lbs.; mix and apply 3 ozs. per square yard, and point in shortly before planting.

When the plants have got well hold of the soil and commenced bearing, use top-dressings of the fertiliser given on page 93, lowest formula, about 4 ozs. per square yard, mixed with three times the amount of sweetened horse droppings or short fermented farmyard manure, supplying at about three weeks intervals.

If the intention is to use the land *in situ*, I advise a dressing of best chalk or land lime, freshly burned, 1½ cwt. per rod, placing the lime in little heaps convenient for spreading, slaking with only sufficient water to cause the lime to fall to apparently dry powder, and whilst hot distribute evenly on the turf. Allow the lime to act for a few days, then bastard-trench the land, placing the turf at the bottom, taking it off about 3 inches thick, and not placing more than 7 to 9 inches of soil upon it, or even not that if the soil be shallow; it will suffice if the turf be so covered as not to interfere with cultural operations.

When the land has been broken up apply a dressing of stable or farmyard manure thoroughly decayed, 1½ cwt. per rod, and ½ lb. per square yard of air-slaked chalk lime and fresh dry soot in equal parts by measure, and dig in with a fork, taking small spits so as to secure even incorporation and not disturbing the turf. Before planting apply 4 ozs. per square yard of the mixture last given on page 93 and point in. After making the soil firm, to insure sturdy growth, put out the plants, and afterwards feed with the fertiliser as top-dressing, according to circumstances, in the manner before mentioned. If eelworm give trouble under the foregoing régime let specimens be kindly sent to the Editor.

"T. P. R." will have seen what Mr. Iggulden has to say about Tomatoes and their diseases on page 174, the "little sensation" having developed into a deluge drowning eelworms and fungi. Albeit some of both appear to have survived the turbulence of the waters, and these Mr. Iggulden disposes of by means of Little's soluble phenyle. It is a remedy apparently and also a preventive, as he says, on page 130, "A soaking of phenyle did good service when used on soil in which eelworms were numerous."

After disposing of Mr. Bradley's dictum that 10 per cent. of lime was not safe by a direct negative proof, "T. P. R." asks if I can account for the Tomato plants he describes going off. Mr. Iggulden demonstrates the same thing—namely, the inefficacy of lime as a preventive of the plants "dying off." This is a phase of the subject I was not unprepared for, as I have found other means of infection than by the soil in respect of fungi.

Of these, three species, if not four, are carried over from year to year quite independently of the soil, and any or all of them may cause "black stripe," "drooping," "sleeping," or "sudden collapse" disease, for the terms are equally applicable to all. Unfortunately "T. P. R." did not submit specimens to the Editor, and in consequence no one can tell him what organism, if any, caused his plants to die off at the "ground level." Even when they are to hand it is not always possible to satisfactorily account for the cause, as the agent may not be present

in the case of certain animals, and in that of fungi not sufficiently developed for identification.

One thing, however, is certain in both "T. P. R.'s" and Mr. Iggulden's case—namely, the plants do not die off without cause; but in neither instance is there anything to show infection by means of the soil. Indeed, the opposite is clearly indicated by the untreated house in Mr. Iggulden's case being quite as free as the others that were treated preventively against fungoid diseases. I say fungoid, because Mr. Iggulden chiefly confines his remarks to the diseases of that class in Tomatoes, and very cleverly points to the advantages of precautionary measures in lessening recurrence and mitigating the severity of attacks by the use of substances that profit him in his culture.

To his banter I take no objection, but am glad to find him making such good use of his "innings" as to show that after all there is only a difference in name between science and practice. Now he is "in" I hope he will not come out until he has told us what Tomato diseases are carried over from year to year with the seed, and can only be avoided by starting with "plants raised from seed saved from fruit grown on healthy plants." Having thus "hit the nail on the head" let Mr. Iggulden clench his arguments by showing us the disease-germ in the seed, tell us what it is, and demonstrate its life history from the pushing of the germ-tube to the reproduction of seed or resting-spore. I can assure him that it is a very practical subject, and so far as I can see just as easy to attain as growing Cabbages.

There is no "mystery" about any organisms causing "troubles" in Cucumbers and Tomatoes; at least, all I have inquired into lead very practical lives, and appear bent on living and reproducing to the best of their power. But even these beings are subject to the balancing forces of Nature, plagues and epidemics breaking out amongst them, which are as necessary to a proper equilibrium as is the importance of adopting repressive measures in civilisation and cultivation in order to prevent the spreading of contagious diseases.—G. ABBEY.]

ROYAL HORTICULTURAL SOCIETY

DRILL HALL, MARCH 9TH.

THE exhibition held on the above date was one of the best that has ever been seen in the Drill Hall, and taxed the space in the building to the utmost. The floral section was nothing short of superb, both for quality and variety. Fruits were not so largely shown, but Orchids were rich in quality.

FRUIT COMMITTEE.—Present: G. Bunyard, Esq. (in the chair); with Rev. W. Wilks (Secretary), and Messrs. J. Cheal, J. H. Veitch, G. W. Cummins, A. F. Barron, J. Willard, T. J. Saltmarsh, F. Q. Lane, G. Reynolds, H. Balderson, J. Smith, T. Farr, G. Sage, A. J. Laing, C. Herrin, W. J. Empson, T. Fife, A. Dean, and J. Wright.

Mr. John Watkin, Pomona Farm, Hereford, sent fruits of Lord Hindlip Apple to show its keeping quality. The fruits were in excellent condition. The award of merit granted last year was unanimously confirmed. Mr. G. Lovelock, The Gardens, Normanton, sent Diamond Jubilee, not unlike Royal Somerset; very acid, and passed.

Mr. Charles Ross sent fruits of Mottled Russet Apple; small, and lacking in quality, and no award was made. Messrs. Lane & Son sent Apple St. John's Seedling, resembling Hornead Pearmain. Messrs. W. & J. Brown, Stamford, sent fruits of Lavender's Seedling Apple, of the Wyken Pippin type, but it lost an award of merit by three votes. Mr. J. Hudson sent from Gunnersbury House Gardens splendid examples of Newton Wonder Apple, the same fruits he exhibited at the Crystal Palace in October—very fine, and a cultural commendation was unanimously awarded.

Mr. G. Wythes sent excellent dishes of Witloof and Asparagus grown under leaves—very creditable produce indeed, and a cultural commendation was at once granted. Mr. Empson, Amptill, sent a collection of Apples, with excellent Seakale, Mushrooms, Asparagus, and Broccoli (silver Banksian medal). E. Dresden, Esq. (gardener, Mr. Tallack), Livermere Park, Bury St. Edmunds, sent thirty dishes of Apples in excellent condition (silver Knightian medal). C. J. Massey, Esq. (gardener Mr. Day), Galloway House, Wigtonshire, sent fourteen dishes of very good Apples (silver Banksian medal).

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with the Rev. G. H. Engleheart, and Messrs. H. B. May, R. Dean, R. Owen, G. Stevens, J. F. McLeod, T. Peed, C. J. Salter, C. E. Jeffries, G. Gordon, J. D. Pawle, J. W. Barr, C. E. Pearson, C. E. Shea, J. Walker, H. J. Jones, H. J. Cutbush, D. B. Crane, E. Beckett, H. Turner, G. Paul, E. Mawley, H. Herbst, J. Laing, J. Hudson, and R. M. Hogg.

Messrs. W. Cutbush & Son, Highgate, arranged a semicircular group of plants, comprising Forsythias, Pyrus, blue Primroses, Ericas, and superb Malmaisons edged with Maidenhair Fern. This was a charming exhibit. Miscellaneous flowering plants were splendidly staged by Messrs. J. Peed & Sons, Norwood Road. *Prunus sinensis* fl.-pl., Azaleas in variety, Lily of the Valley, Cyclamens, and Boronias were conspicuous. From Messrs. W. Balchin & Son, Hassocks Nurseries, came superb Boronias and Primulas, while Messrs. Paul & Son, Old Nurseries, Cheshunt, sent Roses and rock plants. There were Saxifragas, Hepaticas, Megaseas, Primulas, Drabas, Hellebores, and others in pleasing variety.

Well grown plants of Cyclamens in various colours were staged by Mr. W. Slogrove, gardener to Mrs. Crawford, Gatton Park, Reigate. These were good examples of culture. Mr. J. Douglas, gardener to Mrs. Whitbourne, Great Gearies, sent a showy bank of Cinerarias. Plants of

Azalea mollis × *sinensis* seedlings were staged by Messrs. R. & G. Cuthbert, Southgate. They were very profusely flowered. Fibrous-rooted Begonias smothered with flowers and Star Primulas composed the exhibit from Messrs. H. Cannell & Sons, Swanley, who also sent flowers of Cinerarias. Mr. Perkins, gardener to the Hon. W. F. D. Smith, Henley-on-Thames, sent a collection of splendid Amaryllis, including several varieties that have been honoured by the Society in previous years.

Probably the finest individual exhibit in the floral section of the show was that of Messrs. J. Veitch & Sons, Limited, Chelsea, who staged Primulas. The plants, in 48-pots, were dwarf, clean in foliage, and carrying shapely, pure coloured flowers in considerable numbers. Both double and single varieties were represented by dozens of plants. Amongst the singles were the Queen, Veitch's New Salmon, Superb Fringed White, Superb Fringed Red, Gigantic Rose, Gigantic Red, Gigantic White, Chelsea Scarlet, Chelsea Blue, and Gigantic Blue; while such doubles as Lilac White, Blue, Rose, and Salmon were in superb form. The same firm also sent Lachenalias in variety, Rhododendron Early Gem, *Spiraea confusa*, *Cytisus elongatus*, and magnificent Amaryllises, such as Clonius, Leontes, Hecla, Zephyrus, and others.

The St. George's Nursery Co., Hanwell, sent a group of well-grown Cyclamens, producing flowers of considerable size and substance. The fragrance diffused throughout the Drill Hall was from the Freesias staged by Mr. J. W. Mowbray, gardener to Major the Hon. H. C. Legge, Fulmer, Slough. The plants showed admirable culture, the number of flowers that they were carrying being enormous. Cut blooms in boxes and on plants of Camellias from Messrs. W. Paul & Son, Waltham Cross, made a very conspicuous exhibit, such as is too seldom seen at the Drill Hall. The flowers were of the best varieties. Messrs. Paul also sent plants of Rose Enchantress.

Messrs. Barr & Sons, Covent Garden, had a stand of hardy flowers. There were Hellebores in variety, brightly coloured Chionodoxas, profusely flowered Megaseas, Daffodils, besides Saxifragas, and others. Mr. J. May, Twickenham, staged fine Cyclamens; and Messrs. J. James and Son, Woodside, Farnham Royal, Slough, sent Cinerarias remarkable for the high quality of their flowers. The colours were greatly diversified, clear, rich, and the blooms of superb shape and substance. This was probably the finest collection this grower has ever staged. Messrs. J. Laing & Sons, Forest Hill, staged miscellaneous foliage and flowering plants, amongst which Clivias were most conspicuous.

Mr. I. House, Westbury-on-Trym, Bristol, sent specimens of the Californian Violet. It is a fine variety, being hardy, free, and fragrant. Mr. Chas. Turner, Royal Nurseries, Slough, sent baskets of Violets Italia, Princess of Wales, Amiral Avellan, and others. The first prize for a collection of Hellebores went to Messrs. Paul & Son. Mr. G. Mount, Canterbury, staged superb cut Roses, including La France, Captain Haywood, Caroline Testout, Catherine Mermet, and others.

ORCHID COMMITTEE.—Present: S. Courtault, Esq. (in the chair); with Messrs. J. O'Brien, H. M. Pollett, H. Ballantine, J. T. Gabriel, W. H. White, H. A. Burberry, J. Jaques, T. W. Bond, W. H. Young, F. J. Thorne, E. Hill, W. H. Protheroe, A. H. Smee, T. B. Haywood, and C. Winn.

Messrs. F. Sander & Co., St. Albans, staged a small collection of Orchids, including *Miltonia cuneata*, *Lycaste Skinneri*, Cattleyas, and several others. Mr. W. H. White, grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent a few Orchids of great interest. Some superb Dendrobiums, Masdevallias, and Cypripediums were noticeable. Dendrobiums were sent by Mr. Bond, gardener to C. L. N. Ingram, Esq., Godalming, other growers also sending Orchids in variety.

Messrs. J. Veitch & Sons, Ltd., staged a superb collection of Orchids, amongst which many beautiful examples were seen. There were numerous Dendrobiums, *Aspasia* being remarkably well coloured, Cattleyas, Cypripediums, and others.

MEDALS.—Floral Committee.—Silver-gilt Flora medal, Messrs. W. Paul & Son, Camellias; bronze Flora, Mr. J. W. Mowbray, Freesias; silver-gilt Banksian, Messrs. J. James & Sons, Cinerarias; St. George's Nursery Co., Cyclamens; Messrs. J. Veitch & Sons, Ltd., Amaryllis; silver Banksian, Messrs. W. Slogrove, Cyclamens; Perkins, Amaryllis; Barr & Sons, hardy flowers; J. May, Cyclamens; J. Peed & Son, plants; Balchin & Son, Boronias; J. Douglas, Cinerarias; G. Mount, Roses; J. Laing & Sons, plants; and bronze Banksian, Messrs. R. & G. Cuthbert, Azaleas; Paul & Son, alpine plants; H. Cannell & Sons, Begonias and Primulas. Orchid Committee.—Silver Flora, Messrs. J. Veitch & Sons, Ltd., and T. W. Bond; silver Banksian, Messrs. F. Sander & Co., and W. H. White.

CERTIFICATES AND AWARDS OF MERIT.

Bulbophyllum Ericsoni Krangleri (E. Hill).—The sepals of this are green spotted with brown, the narrow petals being green. The lip is maroon (first-class certificate).

Chionodoxa Lucilæ alba (Barr & Sons).—A pure white form of the well-known type (first-class certificate).

Cotoneaster horizontalis (Paul & Son).—A dwarf form, with freely produced rich scarlet berries (first-class certificate).

Cyclamen grandiflora alba (St. George's Nursery Co.).—A fine pure white form (award of merit).

Cymbidium eburneum (R. B. Lowe).—A magnificently grown specimen of this well-known Orchid (first-class certificate).

Cypripedium hirsuto-Sallieri (W. H. White).—The parentage of this hybrid is told by its name. The dorsal sepal is greenish yellow with a broad white band. The lip is greenish yellow sparsely suffused with brown. The petals are soft rose at the tip and yellow at the base (award of merit).

Dendrobium Ashworthi intertextum (J. Veitch & Sons, Ltd.).—This is a chaste variety with white sepals and petals and a cream coloured lip. The throat is bright maroon (award of merit).

Lycaste Skinneri pulcherrima (F. Sander & Co.).—The colour in this variety is softer than in the type.

Masdevallia Pourbaixi (W. H. White).—Orange yellow is the colour of this fine Masdevallia (award of merit).

Odontoglossum crispum, *Ami Charles* (L. Linden).—White, suffused with purple, and with abundant chocolate spots, is the colour of this variety (award of merit).

Odontoglossum crispum Kegeljani (L. Linden).—A fine chocolate spotted form (award of merit).

NATIONAL CHRYSANTHEMUM SOCIETY.—DIAMOND JUBILEE CLASSES.

THE following special classes find a place in the schedule of prizes offered at the exhibition of the above Society at the Royal Aquarium in November next, and are in commemoration of Her Majesty the Queen attaining to the sixtieth year of her reign.

Thirty-six cut blooms of Chrysanthemums—viz., twenty-four Japanese and twelve incurved, distinct, novelties introduced in 1895, 1896, and 1897, or not yet sent out; to be shown on ordinary boards for Japanese blooms; all seedlings and otherwise to be correctly named, the twelve incurved varieties to form the front line of the stand. Prizes—£5, £4, £3, £2. The trade only.

Thirty-six blooms of white, yellow, and crimson Japanese Chrysanthemums, in twelve varieties, three blooms of each, to be shown on ordinary boards, but with 6 inches of clear stem above the boards; Chrysanthemum foliage, not necessarily that of the particular variety, to be shown with each flower, not on its stem, but on a separate stem attached to it. Open to all. Turner Memorial cup and £4, £4, £2. The cup to become the property of the individual winning it two years in succession or three times in all. The cup to be held by the winner from year to year on the same conditions as the Holmes' Memorial cups are held. Exhibitors in the classes for the Holmes' Memorial cups cannot compete in the foregoing class.

Twenty-four dishes of Apples, nine of them to be varieties in cultivation in this country at the time of the accession of the Queen in 1837, the remaining fifteen varieties introduced during the past thirty years, these to have the year when sent out and by whom, placed on the card with the name of the variety, five fruits of each to be shown. The fruits staged in this class need not have been grown by the exhibitor, but must be United Kingdom produce. Open to all. £5, £4, £3, £2, £1.

The undermentioned varieties were in cultivation, among others, at the time of the accession of the Queen:—Alfriston, Ashmead's Kernel, Beauty of Kent, Blenheim Pippin, Cellini, Cornish Gillyflower, Cat's-head, Duchess of Oldenburg, Dumelow's Seedling, Emperor Alexander, Ecklinville, Flower of Kent, Fearn's Pippin, Gloria Mundi, Golden Noble, Gravenstein, Golden Russet, Hollandbury, Hawthornden, Margil, Mannington's Pearmain, Newtown Pippin, Norfolk Beefing, Ribston Pippin, Red Quarrenden, Royal Russet, Scarlet Nonpareil, Waltham Abbey Seedling, and Winter Pearmain.

ELECTION OF FLORAL COMMITTEE.

ON Monday evening last the General Committee of this Society held a meeting at Anderton's Hotel, Fleet Street, Mr. T. W. Sanders being in the chair. The Secretary having introduced that gentleman as the new Chairman of the General Committee, he replied, expressing his desire to hold the reins impartially, and hoped to do honour and credit to the Society in his new position.

The minutes of the previous meeting were then read and confirmed, after which several elections took place, the principal one being that for the Floral Committee. Messrs. Crane and Taylor were nominated as scrutineers, and it was a noticeable fact that competition on this occasion was anything but severe. There were seven vacancies to fill and only nine members proposed. The following were successful, figures after the names being the number of votes that each candidate obtained.

Messrs. E. Beckett, 32; T. Bevan, 30; W. Mease, 32; R. Owen, 27; Geo. Stevens, 30; J. H. Witty, 32; and Higgs, 20.

A vacancy having also occurred on the General Committee Mr. Willis was elected to fill the place. It was then proposed and carried that Mr. Thomas Bevan should again be Chairman of the Floral Committee.

TADCASTER PAXTON SOCIETY.—On the evening of March 4th Mr. M'Intosh, York, read an excellent paper before the members of the above Society on "Some Thoughts in Connection with Potting, Watering, and the Growth of Plants." The greatest interest was evinced by the members present, who passed a hearty vote of thanks to Mr. M'Intosh for coming from York to read such a scientific and practical paper.

WEATHER IN LONDON.—The weather in London during the past seven days has been most unpropitious both for plant and human life. The frequent rains with the heavy gales of wind have done much damage, and it is almost impossible for any work to be done on the land. Nearly every day since our last issue went to press rain has fallen more or less, though on Tuesday morning there was a sharp white frost. At the time of going to press on Wednesday it is bright and fine.

WEATHER IN THE NORTH.—There has been frost of from 2° to 5° on three mornings during the week ending the 9th inst., and on several others the thermometer has stood at 32°. While cold winds have been prevalent, some of the days have been fine, Sunday especially so for the season. Monday was colder, and Tuesday morning disagreeably wet, with cold easterly wind.—B. D., *S. Perthshire*.

ROYAL BOTANIC SOCIETY.—At a meeting of this Society held last Saturday, Mr. John Birkett, F.L.S., in the chair, the Duke of Bedford, Sir G. Hamond Græme, Bart., and nineteen others were elected Fellows. A paper was read by Mr. Martindale, calling attention to the great desirability of establishing in London an institution for the purpose of teaching botany similar to those in existence on the continent, and proposing that the Council should take charge of the scheme and utilise a portion of their ground for the erection of the necessary buildings. Among those present who gave the scheme their hearty support were Professor Oliver, of University College; Mr. D. H. Scott, of Kew; Professor Henslow, Professor Greenish, Mr. M. Carteghe, and Mr. E. M. Holmes of the Pharmaceutical Society, and many other eminent scientists.

DEATH OF MR. CHARLES SHARPE.—We regret to hear of the death of Mr. Charles Sharpe, in his 69th year, which is said to have occurred rather suddenly at Sleaford on Monday last. The deceased gentleman was head of the great firm of seed growers and merchants, which has long enjoyed, as it deserved, a national reputation. Mr. Charles Sharpe was widely known and respected in the Kesteven division of Lincolnshire, in which he resided, and of which he was Magistrate and Alderman, also a prominent member of the County Agricultural Society. Mr. Sharpe was a gentleman of broad views, a sturdy friend of allotment holders and farmers, but they were not quite strong enough to return him to Parliament in contest with his then powerful neighbour, Mr. Chaplin of Blankney, and now President of the Board of Trade. The Blankney estate is now, we understand, in the possession of Lord Londesborough.

WAKEFIELD PAXTON SOCIETY.—Mr. A. E. Benney of Bradford was the essayist at a recent meeting, and his subject was "All About a Daisy." Mr. Milnes, J.P., presided, Mr. J. G. Brown being in the vice-chair, and there was a large attendance of members. Mr. Benney said the Daisy belonged to the Compositæ, the largest natural order of plants, and which had more flowers or florets than any other family. There were 100,000 plants in this order, and 10,000 of them belonged to the Daisy family. A single Daisy would have from thirty to forty flowers; they multiplied by offsets, not simply from seed, and in their growth they exterminated all surrounding vegetation. The Dandelion, Chrysanthemum, Dahlia, and Anemone were of the Daisy order. By means of diagrams Mr. Benney clearly illustrated the peculiar structure of the leaves and florets, and also explained the process of fertilisation of the seed.

BIRMINGHAM GARDENERS' ASSOCIATION.—The fortnightly meeting was held recently in the Athletic Institute as usual in the hope of hearing a lecture, entitled "Orchids and Orchid Hunting," by Professor W. Hillhouse. Owing, however, to illness he was unable to be present, but sent an excellent representative in Mr. A. H. R. Buller, B.Sc., of Mason College, who discoursed on "Insectivorous or Carnivorous Plants" before a large and appreciative audience. The highly interesting subject was illustrated by models and diagrams of the various plants embodied. Especially interesting were such as preserved specimens of the "pitchers" of *Nepenthes Mastersiana*, and others of the class, as insect catchers and devourers, as likewise was a large model of "Venus's Flytrap" (*Dioncæa muscipula*). Various other insectivorous plants were also adverted to. The pleasure of the meeting was further enhanced by a display of cut flowers.

GARDENING APPOINTMENT.—Mr. William Pither, for the past seventeen years with Mr. Weaver, Oakley Hall Gardens, has been appointed head gardener to W. W. B. Beach, Esq., M.P., at Oakley Manor, Basingstoke.

SUTTON'S STAR PRIMULA.—This was one of the most useful plants for grouping during the festivities of Christmas. With tall Crotons, Palms and Poinsettia, and a carpet of Maidenhair Fern, a light and most effective arrangement was made. It also makes a first-class plant for decoration in the conservatory.—T. W.

PRESENTATION TO MR. F. JORDAN.—The Duke and Duchess of Portland have presented Mr. Jordan, gardener, Impney Hall, Droitwich, with a valuable silver teapot bearing the following inscription:—"Presented to Mr. F. Jordan by the Duke and Duchess of Portland, on leaving Welbeck—September 18th, 1896." The above is a much-prized and valuable addition to the numerous presents Mr. Jordan received on leaving Welbeck to take charge of the gardens at Impney.

ISLE OF WIGHT HORTICULTURAL ASSOCIATION.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held on Saturday last at Warburton's Hotel, Newport, when Dr. Groves presided over a large attendance. A paper was read by Mr. F. Lee, on "Winter Vegetables," on behalf of Mr. W. Tribbick, F.R.H.S., gardener to Sir Chas. Seely, Bart., Brooke House, I.W., who through ill health was unable to be present. The requisite details were touched upon in an interesting and practical manner. Votes of thanks were accorded the essayist and reader of the paper.

STORM EFFECTS IN THE ISLE OF WIGHT.—The storm which set in on Tuesday, March 2nd, and continued throughout the night and Wednesday morning did much damage in the Island. The weather the week before was so settled and mild I was going to pen a few lines on the earliness of the season, but this was upset by the appearance of March, which came in like a lion. In addition to the destruction of greenhouses, slates and tiles were scattered in all directions, and many people miraculously escaped being injured. But what we greatly deplore is the loss of large Elms and other trees in various parts of the island, which will greatly mar the picturesqueness and beauty of the undulated Garden Isle, and which it is impossible to replace. The exact number of trees blown down by the gale is not known, but according to reports there will not be far short of a thousand.—S. H.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THERE was a fair attendance of members at the annual general meeting of this excellent Society, which was held at the Caledonian Hotel, Adelphi, on Monday evening last. Mr. Alexander Dean occupied the chair. The report of the Committee was as follows:—

"The Committee have great pleasure in presenting to the members the annual report and balance sheet for the year ending January 11th, 1897. The Society continues to prosper, the net increase of members being sixty-six. One benefit member and one lapsed member died in the early part of the year, the amount standing to their credit being paid to the widow in each case. Mr. James George (late Trustee), having reached the age of seventy, withdrew the amount standing to his credit (£82 10s.). The amount of subscriptions paid by members to the Benefit Fund, including arrears of 1895, was £1010 1s. 10d.

"The sick list has again been a heavy one, the sum of £196 15s. having been paid to fifty-one members. The deductions from members' deposit account to meet this amount is 7s. 7d., and 5s. in the two scales of contributions respectively. Subscriptions to the Benevolent Fund from benefit and honorary members amount to £134 10s. 6d. Small sums, amounting to £12 3s. 6d., have been granted to four members from this Fund. The Convalescent Fund is steadily increasing, the amount received being £18 12s., including £3 3s. from W. J. Nutting, Esq., and £5 from N. N. Sherwood, Esq., at the annual dinner. Three members were benefited from this Fund to the extent of £3 10s. The Management Fund shows a balance of £44 14s. 7d. The Treasurer has again invested £1100 during the year in Corporation (3 per cent.) Stock, and has a fair balance in hand.

"The annual dinner was held at the Holborn Restaurant under the presidency of W. J. Nutting, Esq., who fulfilled his office in an admirable manner, and kindly paid for the music. The accounts have again been carefully audited by Messrs. W. Gunner and Geo. Dixon, and found correct. The Committee specially invite all young gardeners and seedsmen to join this excellent Society, feeling sure they cannot do better than join the good ship 'United.'

"The financial aspect of the Society is good, and speaks well for the excellent manner in which its business is conducted. This is one of the best societies that young gardeners can join, as it confers benefits decidedly superior to any of those given by societies outside the craft." We heartily endorse the last sentence in the report of the Committee.

The customary votes of thanks were accorded to the Chairman and the several officers of the Society.

LOCKINGE PARK, THE SEAT OF LORD WANTAGE.

LOCKINGE, the Berkshire home of Lord and Lady Wantage, is a name to conjure with in the world of horticulture, for it is customarily taken as synonymous with quality and enterprise—indeed, one does not expect to see or hear of anything weak in connection with the place. Tree planting is the hobby of Lord Wantage, and gardening generally of Lady Wantage. The soldier Lord follows his bent in no half-hearted manner, purchasing trees of all kinds by the 100,000 for placing on different portions of the estate. Each site is selected with care and judgment, with the result that in the majority of cases success crowns the efforts made. Ready and willing to carry out all expressed

man it must be earned, for there can be no question of purchase. A soldier no longer, Lord Wantage still retains his interest in all matters pertaining to the military, though now horticulture and aboriculture come in for a considerable share of attention. The result of this enthusiasm is seen on every hand, and the large estate is rapidly becoming more and more beautiful, and let us hope increasing in value at a similar ratio. Delightful walks and drives abound in all directions, and magnificent views of real English landscape are spread before the wanderer as he passes on his way. In brief, it is one of Mrs. Heman's "stately homes of England."

FIG. 42 —ALCOVE AND FOUNTAIN.

wishes of this nature is Mr. W. Fyfe, the esteemed head gardener, much of whose time during the winter season is taken up by going from place to place to superintend the planting.

Energetic as is his Lordship as a tree planter he was equally as much so in his younger days as a soldier, for he gained an enviable renown on the heights of Alma when he held a lieutenant's commission. It was there, where hundreds of brave men found their last resting place, that the greatest honour that can be attached to a man was given to Lieutenant Lloyd Lindsay—the Victoria Cross with its simple inscription "For Valour." Proud indeed may he be who wears this decoration, for it is given for merit alone. Whether it be awarded to officer or

The first week in March would not be considered by many of our readers to be an ideal time to see a garden, because it cannot be expected to find the trees laden with the fruit, the plants rich in bloom, and the whole sweet with Flora's and Pomona's fragrance. But none the less, a garden to a gardener is always interesting and mostly instructive, especially when the visit is the first that has been paid to some particular place. Such being the case, the pilgrimage to Lockinge was made with much pleasure and tended to the writer's profit, and though it cannot be written of as at the zenith of its beauty, there are many things that may be noted here. For the garden at its best we had perforce to rely on that excellent delineator the camera, and its pictures, reproduced in figs. 42, 43, and 46, on pages 201, 208, and 209, speak volumes about Lockinge, and render the task of describing it far easier

than it otherwise would be. No formal history will be given, but simply a few jottings of features of more than ordinary merit in some one or more respects.

From Wantage Road Station the visitor has a drive of upwards of two miles ere the old-time village of Lockinge, with its ancient structures, charming gardens, and splendid trees is passed. To reach this a road is traversed which for almost its entire length has been made, and is maintained by the owner of the estate. This goes up hill and down dale, now between green meadows dotted with live stock, there through banks, on which shrubs and trees have been planted. The yellow Broom will be gloriously beautiful when in flower. The Honcysuckles will disperse their fragrance, while the Buckthorn will do its part towards the constant change throughout the summer months. Every effort has been made to insure simplicity both in the choice of plants and also in the system of planting here, and the result must be decidedly gratifying. Many of the houses in this village have been rebuilt, as also has the schoolhouse, but no modern style of architecture has been chosen, and rightly, for this would be quite out of keeping with the older houses that remain as emblems of the past.

The secluded hamlet has not long been left when we come within sight of the mansion, showing conspicuously between the trees; but no pause is made until Mr. Fyfe's house is reached. It is a typical old English farm house, in which until quite recently, one family has resided for about 400 years. Without, one notes the appearance of strength, of solidity, with perhaps little of beauty. Within, the rooms are peculiar in shape; they have great oaken beams in the ceilings, and a natural air of comfort. The house is English, the home is English, while the welcome was English too. It is a greeting that tells you you are at home without any of that boisterous flattery that has sometimes the contrary effect to that which is intended. With Mr. and Mrs. Fyfe the visitor was at home at once, and their hospitality was acceptable after the long and tedious journey that had been made.

But there can be little rest when a garden is to be seen, and in a very short time a move is made towards the garden with its flowers, fruit trees, vegetables, and houses. Look at the illustration (fig. 42) which depicts a charming corner in one of the secluded flower gardens. The photograph was taken in the summer, and shows the recumbent nymph with the water flowing over her from above into the semi-circular basin in the foreground. The handsome stone framework is enveloped in verdure, not trained, but allowed to grow as naturally as may be; the sides being flanked with handsome Ferns. The rising background is clothed with plant life, while in the front is a small almost circular garden laid out for plants of various kinds. It is a spot where one might linger long in the cool of a summer day to enjoy the peace and beauty, the fragrance and variety of an English home. The eye can roam amidst things that charm the sight, while the ear is greeted with "the song of birds and the murmur of trembling leaves."

By hard and smooth gravel walks, past trees of stately grandeur, over lawns of velvety softness we wander, securing by the way a fine glance at the mansion. An immense structure is this, built apparently for strength and not for ornament. It lays in what the poet Gray would term "a cool, sequestered vale," and is surrounded by lawns, gardens, slopes, and hills, these latter being magnificently timbered. At various points within the range of sight, where trees were not so numerous, are seen plantations formed by his lordship, and which already have influence for good in the pastoral picture. These trees will be fitting memorials of their planter's career, for long after he has passed away they will bend with the wind, and the future dwellers at Lockinge will say "those were planted by Robert, Lord Wantage, and still remain as living testimonials of the one who from the turmoil of battle turned to the peace of a rural life, and found it in this ideal English home."

It is a scene of beauty that is depicted in the photograph on page 208. To the left may be seen the church, to the right the mansion, with a corner of the conservatory, while in the front is a series of beds that are gay with flowers in the summer. There is God's acre, too, by God's house, and all near here is as if hallowed by the presence of these—it is the serenity of perfect peace. To the left of the photograph, and also occasionally amongst the beds, may be seen large vases filled with plants, and whose sides are festooned with leaves and flowers. Look at these, at the Ampelopsis on the wall, at the trees in the back, at the creeper on the church, and at the beds in the front, and read in them the knowledge that it is summer. Things are different now, yet not without their charm.

Though the mantle of winter is over the flower garden within the conservatory is found the brightness of summer. Flowers are there in plenty, even a few dazzling Poinsettias still remain to add variety. Scarcely less bright in colour are the small flowers of Euphorbia jacquiniæflora, whose stems are wreathed with blooms. There are besides these Tulips, Hyacinths, Spiræas, the simple yet deliciously perfumed Mignonette, while in a central basin are seen Arum Lilies at home. The milk-white spathes and noble leafage rise from the water with telling effect. Depending from the lofty roof are creepers, with hanging baskets containing Ferns. Large Palms command attention, as does the structure itself, which is entered by a broad corridor. Unlike many conservatories of similar dimensions, the plants seem to thrive in a very satisfactory manner.

Look now at another scene in which flower beds, trees, lawns, and the creeper-clad house are all comprised. This is on page 209. How different is it from the view to which allusion has just been made! It serves well to illustrate the diversity of scenic effect that is here found better than could the word painting of a Carlyle or a George Meredith, though not so well as the canvas painting of a master hand, such as a Turner or a Linnell. As may be seen at a glance this garden is on a much higher level than is the mansion, and is similar to the other in being quiet and secluded. Simple styles of bedding are in vogue at Lockinge, and it cannot be doubted for a moment but that they produce a splendid effect. The flowering and foliage shrubs here, as elsewhere in the gardens, are very numerous, and represent large numbers of species and varieties. Cut flowers being a desideratum those are largely grown that provide these in the most liberal quantities. The selection having been skilfully done flowers of one kind or another are to be had over a considerable portion of the year.

Away now we go to see the houses, entering first the one in which that prince among Melons, Hero of Lockinge, found its origin. No need to dwell upon its merits here, for it is a favourite in every place all over the country where Melons are grown. There are some young plants just coming on now which, given fine weather, will render a good account of themselves later on. Cucumbers are there also in splendid health that will have to do their share towards filling the supply. By the way, the Lockinge system of Cucumber culture is to maintain a continuous round of young stock, for immediately a plant has passed its state of greatest productiveness it is removed, and its place taken by another. Mr. Fyfe is a thorough believer in this plan. The first plants of the year are always cultivated wholly in pots, the succeeding ones of course being placed on beds in the ordinary way. No eelworm is found, and one might safely add none is wanted. There is a Tomato too that might well be termed Hero, but is known only as a Champion.

Cyclamens are quite a speciality at Lockinge, where they are magnificently grown. In 48-pots there are now dozens, or rather scores of plants still carrying hundreds of flowers. Not that they are now at their best. They commenced to flower in November last, and as they have been on the go ever since they could not be expected to be absolutely faultless. The seeds from which the plants were grown were sown in October, 1895, so that when blooming first commenced the corms were only thirteen months old. Several of the varieties are Sutton's best. Primulas, too, are grown up to the mark, and some little plants of Chelsea Red in small 60-pots are smothered with blooms. The colour of this variety is very rich, and the flowers are of fine form and substance. Other newer single varieties are there, with doubles in abundance. As these latter are valuable for cutting they have a large amount of attention devoted to them, which they amply repay by the freedom with which the delicately beautiful flowers are produced.

In addition to the plants mentioned in the preceding paragraphs there are all those others customarily grown for the supply of a first-class establishment. Of foliage plants large numbers have to be maintained, because they are in such constant demand for purposes of decoration in the mansion. Naturally enough, considering the handsome colours of their leaves, Crotons are largely utilised, as also are Dracænas, Ferns, Pandanus, Palms, and others. Some of the specimens of the first-named in small pots are remarkably handsome, and perfectly adapted to the purpose for which they are grown. The collection of Orchids, too, is worthy of more than the passing glance that can now be accorded to it, for it comprises some splendid plants of many good Cattleyas, Lælias, Cypripediums, Odontoglossums, Cœlogynes, Thunias, and others, all of which are in the pink of condition, with their clean healthy leaves and substantial, fully developed pseudo-bulbs.

Another adjournment must now be made, this time to see the fruit trees under glass. Peaches and Nectarines in the earliest houses are splendidly set with fruits, while other trees are sheets of flowers. Straight, and free from pests, is the wood of these, as well as of the Vines. In the earliest vinery the bunches are numerous, and the foliage is wonderfully healthy. All the best varieties of Grapes are represented in the various houses, and all so far look remarkably well. The borders in which the roots of the Vines are feeding are comparatively small, but there is no lack of nourishment, this being applied from the surface, with the result that just beneath the top it is a mass of fibrous feeders. Figs are great favourites at Lockinge, and are in the most luxuriant health. Not so gross, however, as to be detrimental to fruiting, but in such condition as to produce the fullest of crops.

The splendid walls that surround the vegetable garden are almost entirely covered with fruit trees, amongst which Pears and Plums are conspicuous, by reason of their excellent condition. They are beautifully trained, and the cleanliness of the wood, the strength and abundance of the buds, testify to the correctness of the treatment to which they are subjected. Other portions of the wall are occupied with different kinds of fruit, though one corner was noted that had been devoted to Roses. Fruit in the open is equal to that on the walls, and some small bush trees planted on the surface are in perfect condition. They were placed practically on the level, because there was no soil in which to plant them, and year by year they continue to give surprisingly satisfactory results. Now they are studded with fruit buds, and promise to produce crops equal in quality to previous years.

The vegetable quarters are not very fully occupied just now, though all is in readiness for sowing and planting with the various kinds that are so largely grown. In one of the houses are thousands of young Pea plants—American Wonder—from seeds sown in February, and which will produce the first pods of the season later on. As soon as large enough and during suitable weather these will be planted in the open ground. Of Asparagus and Seakale there is abundance, the former being forced by simply laying the old stools beneath stages in the vineries, where they are warm and kept pleasantly moist. The system involves little labour and gives excellent results. After forcing the old plants are thrown away. French Beans in pots are very fine, but to see the vegetable garden in perfection a journey would need to be made much later in the year.

A glance into the fruit room, where are seen Apples in great numbers and several bunches of Grapes, and we return to partake of Mrs. Fyfe's hospitality. A rest and the road for the railway station is started upon to the accompaniment of a deluge of rain and the howling of the wind in the trees. The morning was bright and sunny, the day quiet and enjoyable, the evening boisterous and uncomfortable, but after the reception received and the walk round the estate even this could be borne in contented silence.—H. J. WRIGHT.

WALKS AND TALKS IN KEW GARDENS.

A LITTLE while ago Mr. J. Gregory delivered a very interesting and instructive lecture on the above subject, illustrated with dissolving views, to the members of the St. Barnabas Gardeners' and Amateurs' Improvement Society at Sutton, Surrey. The lecturer first introduced his audience to some fine views of Kew Bridge, The Green, main entrance to the Royal Gardens, thence to the Palms and Aroids, Philodendrons and Monsterae, all being very well shown. Then followed a visit to the Museum, with photographs of the huge specimens of timber that are to be found there. Then he took us to the Orchid house, showing a magnificent group of Cypripediums. The Nymphaea house was next illustrated, and interesting information given regarding the propagation and the peculiarity of flowering of the giant Water Lily.

From the large Cactus house we were shown a specimen of one of Nature's giants in *Cereus giganteus*, which is about 6 or 7 feet of solid succulent tissue, and nearly a foot thick. This was followed by pictures of Euphorbia in flower drooping from the roof, Aloes, Opuntias, and others. On leaving this house we were shown some grand views of the Great Lake with the Palm house on the opposite side, which at all times of the year is more or less interesting.

We were shown some beautiful pictures of Palms, which included the Date (*Phoenix dactylifera*), Cabbage, and Cocoa-nut Palms; also Bambusas and Musas, with here and there a Vanilla plant climbing in tropical luxuriance.

From the Palm house we were given a view of the unassuming building which contains the splendid results of years of untiring energy of Miss Marianne North, whose paintings of plants, for the most part painted in their own native homes, are, to say the least, grand. There are some 800 oil paintings of plants from various parts of the world. Then followed a visit to the Science and Art Museum, and to the economic plant house, where photos of several varieties of the Citrus family were shown. The cultivation and early history of the Cinchona were next touched upon. This, in combination with sulphuric acid, is what quinine is made from, which to residents in hot and malarial countries is an absolute necessity.

Photographs of the Pagoda, avenues, rock garden, and other choice corners of the Gardens brought to a successful termination a most pleasant and interesting evening. Apart from the lecture were shown some exquisite photographs of individual plants which I believe Mr. Gregory is making a study of, the most noticeable being some trained standard Chrysanthemums, Narcissi, Orchids, and Spiræas.—W. H. WALKER.

LIVERPOOL NOTES.

PRESENTATION TO MR. R. PINNINGTON.

THE first meeting of the session of the Liverpool branch of the National Amateur Gardeners' Association was held in the Common Hall, Hackins Hey, Liverpool, on Thursday evening under the chairmanship of J. C. Glover, Esq., the newly elected President, there being an excellent attendance. The President, in his opening remarks, said he would not take up the time of the meeting further than to say that reports had been circulated to all members. In this report, while the Committee regret a falling off in members, they congratulate themselves that those who have retired were the "drones," the non-workers, and that those who remain are taking an active and intelligent interest in the work of the branch.

The financial state of the branch has greatly improved, thanks to the energy displayed by the new Secretary, J. C. Langley, Esq., and after setting aside 7 guineas for prizes the branch has a balance in hand of £12 9s. 11d. to commence the year's working—the largest balance they had ever had. He was glad to say that quality of exhibits was on the improving side, which was to his mind a matter of great importance, as was also their encouragement of junior members. He hoped they would go on and prosper, and help to support the Association in every way. Medals and certificates were then presented. Mr. A. Dodd,

Aintree, was awarded the silver medal, and Mr. Arthur Dale, Egremont, the bronze medal.

A very interesting feature of the meeting was the presentation by the President (on behalf of the members) of a handsome silver-mounted cigar case to Mr. R. Pinnington of Roby, Liverpool, representative of the *Journal of Horticulture*. In making the presentation the President referred to the kindness shown to the members by Mr. Pinnington in attendance at the meetings, to which he often came at much disadvantage to himself, always bringing something choice from the gardens under his charge; by his useful advice, which he so readily accorded; and for the valued reports from his pen; and he now asked Mr. Pinnington's acceptance of the gift, as a small mark not only of their appreciation but of their esteem and friendship. Mr. Pinnington replied in a brief but suitable manner.

An interesting display of plants, such as Cyclamens, Azalea mollis, *Cœlogyne cristata*, and Dracenas; the prizes awarded being to Mr. Cangle, Formby, for Tulips; and certificate and special prize to Mr. J. C. Langley, for grand blooms of *Calla æthiopica*—a fine exhibit.

To inaugurate his first year as President, Mr. Glover afterwards entertained a large number of members to a smoking concert at the Alexandra Hotel, Dale Street, where he dispensed hospitalities in his usual kind way, the programme being of a very high-class order. Mr. Ardman and Mr. Histed eulogised the services of Mr. Glover as President, and with Mr. J. C. Langley (Treasurer), and Messrs. J. M. Smyth and G. Gillanders as Joint Secretaries the Liverpool Branch ought to make rapid strides, and be to the fore in all the good work it is trying to accomplish. A capital syllabus for the ensuing session has been fixed, and the work that it is proposed to carry out cannot but be conducive to good. The names of several new members were proposed.

AXES TO GRIND.

I WAS a very interested listener to the admirable paper Mr. G. Gordon read on the evening of the 3rd inst., before the members of the Society of Arts, at their house in the Adelphi. Even the presence of the Director of Kew, Mr. Thistleton Dyer, as chairman, was insufficient to attract a large attendance, and one could hardly help realising the incongruity of dealing with such a subject, though undertaken by the special desire of the Society, in such a locality as the Adelphi.

Had the paper been read before the Chamber of Agriculture, or the Royal Horticultural Society, or the Fruiterers' Company one could have understood the nature of the connection of the subject with these bodies. Really, as dealt with by Mr. Gordon, it seemed to have most relation to agriculture, especially that the orchards chiefly referred to, and which generally have got into such a deplorable condition, are chiefly farm orchards.

It may as well be admitted at once that whatsoever may be done in relation to cider production, a matter somewhat outside horticulture, by farmers, it is utterly useless to look to them as a body to improve fruit culture, or to give to the nation those immense supplies of fruit which are so much needed, if it is hoped or purposed to displace by home-grown produce the enormous imports of hardy fruit from other countries.

Mr. Gordon had his axe to grind, but it was like my own, a most unselfish one. He wishes to see hardy fruit culture all over the kingdom made into a living reality, because he is a gardener and has a gardener's ideas as to present defects and how they should be remedied. I grind that axe too, and so also, I think, does everyone who wishes to see our Old England converted into a great fruit-producing kingdom.

But there was at the meeting yet another axe to be ground, for that imperturbable advocate of cider (for is he not a member of Parliament for a cider-making division of Hereford?), Mr. Radcliffe Cooke, made a long speech in favour of cider—improvement and production. That seemed to me to be the drawing of a fishy trail across the object Mr. Gordon had in view. Cider may have its interest for those who like it, but it has little for those who want to see vast quantities of fine Apples and Pears grown for cooking and eating.

The next axe was found in the hands of a gentleman interested in artificial storage, who thought that through such agency much might be done to extend the season of our fruit supply. There may be something in it; but if cold storage means, as evidently it does, that the fruits must be kept in a very low temperature for a long time—then we should like to know more as to their condition of flesh and flavour before agreeing. One of these grinders said Apples had in this way been kept four years. It would have been interesting to ascertain what edible value they had after so long keeping.

Then there was yet the Evaporator with his axe, and he thinks much might be done to extend our Apple supplies by evaporating the fruit. It really seemed as if the announcement in the Press of this particular paper of Mr. Gordon's had brought together a fine collection of axes, with the unfortunate result that the discussion on a matter of the very first importance to the welfare of the nation drifted off into side issues, and the great purpose of the paper was overlooked. That was perhaps an almost inevitable result of the reading a paper to an audience so few of which had any knowledge of the subject.

It is hard to induce persons who have axes to grind, that in this case grindstones are not required. We need a real reaction from existing slovenly and ignorant practices to high-class fruit culture. We want fine fruit as food not to be destroyed in any process. That is true pomology. It looks even now as if some fifty years would have to elapse ere the people of England rise to the situation.—A. D.

A RESTING TOUR.

(Concluded.)

LAST on the roll of resting places of the wandering pilgrims during their autumn tour in the North, but now facing the engine for the great Mecca of the South; last but not least worthy of a few "scrappy" notes—mere memory dregs of a few "happy" hours—is Drumlanrig. Than this there are few more familiar names in the gardening world, made so by famous men, not the least of these being he who soon retires from the scene of his long and brilliantly successful labours, Mr. David Thomson. A head gardener for half a century; if any man has won repose it is he whom his "old pupils," most of them no longer young, commendably desire to honour.

It has been said by a great traveller in missionary enterprise, who was a revered guest in many hundreds of homes during his long and remarkable career—"You never really know a man until you have lived with him." Such men as those whose names are mentioned on page 179 last week, and who rank amongst the best of British gardeners, have lived with Mr. Thomson, and proved him—proved his zeal and capacity in the discharge of his duty; his solicitude for the competency and welfare of those who have had the privilege of serving under him; his high sense of justice; his clear head, and his good heart. All this they have proved, and in the action they are taking they are unconsciously, but certainly, doing honour to—themselves.

"Fifty years head gardener!" What a term in a worker's life! Long for the young to look forward to; much shorter for the old to look back upon. Once remarked an octogenarian to the writer, "When I was a lad at school the time seemed to crawl—so long between the holidays; by-and-by it began to walk; after I was fifty it seemed to run; and now (at eighty) it gallops." Such, no doubt, is the experience of most who have lived through two and a half generations. Wise it is to use time worthily and well when young, and always. Mr. Thomson is not an octogenarian, though it is hoped he will be, also hale and happy then.

From the beginning of his career in gardening he was diligent as a student, worker, and experimenter, and always a close observer, he developed into one of the best practitioners in the kingdom and most effective writers on gardening. In character ever modest and retiring, in disposition quietly genial, also obliging without fussiness and demonstration. He has lived a prudent life, and used time well. An apology is now due and tendered to Mr. Thomson for writing that which, in itself, he would prefer had remained unsaid, but will respect the motive and object in saying it—namely, that the short and true record may tend to exert a wholesome influence on those gardeners of the future who are now in the (time) "walking" period of life.

FIG. 43.—MR. DAVID THOMSON.

Perhaps it may be worth saying, for the benefit of those constitutionally unsettled members of the gardening community who are always wanting "fresh and better places," but who have scarcely patience to wait for them, that though Mr. Thomson has been a head gardener for half a century he has only as such had (save a term of less than two years) three situations. It does not seem long since "Davy," the late foreman at Wrotham Park, Barnet, was appointed gardener at Dyrham Park in the same district. There the young man of twenty-four went to work in a thorough manner. Finding a cold, tenacious, unworkable, culturally useless clay, he obtained permission to burn it—not into ballast but friability. This was done to a depth of

2 feet. It was a great piece of work, but had great results—marvellous productiveness, and "Davy's Brussels Sprouts 6 feet high" were the talk of the country side. The press made the achievement widely known, and the young man won his spurs as a sound practical gardener.

It may have been there also (and if not there it was certainly somewhere), that Mr. Thomson revolutionised the method of propagating Zonal Pelargoniums. It was the result of his observant faculty and taking a lesson from Nature. The old established method of rooting cuttings of these plants was in accordance with the stereotyped formula of "keeping them close, moist, and shaded," the same as Fuchsias and other thin-stemmed soft-wooded plants. Thus the "Geraniums" gave endless trouble by damping. Sometimes half the cuttings would "go off," sometimes more, as the writer can remember. Mr. Thomson, observing some trimmings of the plants thrown on a heap of vegetable soil in the full sun first wither, then revive, examined them more closely, then found that the stems in

contact with the soil had emitted roots. Reflection led him to think that such fleshy stems could afford to lose some of their moisture, and he put the matter to the test of practice. Not only was the surmise correct, but all the cuttings rooted, with the great advantage of firmer plants for passing the winter without loss, and becoming sturdier and more floriferous than those raised in the orthodox way. How simple and natural the whole process seems now, and has been so regarded for many years! But comparatively few are aware that Mr. Thomson was the Columbus of the whole matter, and it is well that the fact be recorded.

From Dyrham Park to Archerfield was the first move of the progressive gardener, and there he added to his fame as a flower gardener, Grape grower, and general practitioner. The flower garden which he formed and furnished near Dirleton Castle (a ruin on the Archerfield estate), was in its way, and for many years, one of the finest examples of the massing system in the kingdom. From Archerfield Mr. Thomson went to Drumlanrig, and there he has remained trusted and respected by his ducal employers and

employés for twenty-eight years, and he expects to move to a "shantie" he has secured with a "good big garden" on a walled-in "estate" on 28th of May. He has had a "good big garden" to look after all those years on an estate of 250,000 acres, so will scarcely be overwhelmed by his new undertaking.

It was presumably at Drumlanrig that Mr. Thomson made another discovery from which manufacturers of insecticides have profited, and many gardeners benefited—the value of petroleum as an annihilator of insects on plants and trees, and which now forms the base of many preparations. The discovery was the result of several experiments resorted to to meet a particular case, and when the efficacy and measure of safety of the powerful agent was proved by various tests, the particulars were given to the world through the Press. The use of petroleum has become so general in gardens, that the originator of it as an insecticide is perhaps hardly thought about, and certainly by many not known, and that is why the facts of the matter are registered here.

The gardener's home at Drumlanrig is a delightful place to rest in; situated high up the side of a bold tree-clad hill, and reached by "screwing" paths, the view across the kitchen gardens and for miles beyond, with a crescent-like range of mountains in the far distance is grand. The weather was not of the best in mid-September, but we managed to pass through the gardens and pleasure grounds between the showers, also have a glance through the stately Castle standing in solitary grandeur in such a position of bold natural beauty as it is rare to find. From the terrace we have seen the extensive flower garden a blaze of beauty; but as in many other establishments flower beds have to a large extent given place to a greater expanse of lawn, and it cannot be said in this instance with loss of dignity, as grand trees on smooth greensward have a distinctly imposing appearance.

A flower garden on a level with the Castle on one side was as gay as a garden could be. On the other side the large beds were occupied in a very different manner, and equally ornamentally in their way. This is called the "shrub garden." At intervals are pyramidal specimens of Golden Cypress, Retinosporas, Green and Golden Yews, and Thujaopsis. Many Golden Hollies are also employed, and the ground between covered with such plants as Cotoneasters, variegated Periwinkles, and hardy Heaths. The pleasing association of the different kinds, so diverse in habit and colour, form a distinct and effective feature, and the beds are permanently attractive. The pleasure grounds comprise some 50 acres, and look which way we may from the Castle terraces, east, west or south, we cannot fail to perceive that the site was wisely chosen for a home some 200 years ago.

Returning to the kitchen gardens, a mile from the Castle, a few of the main features may be briefly noted. Six acres are enclosed with walls, and there is a large outside area, that next the gardener's house being mainly lawn and hardy flowers, with long wired arcades of Roses and other climbing plants, the northern boundary being the 500 feet long span-roofed house, 18 feet wide, open from end to end, and heated by 3000 feet of piping. The trellises are clothed with healthy and productive fruit trees—Peaches, Nectarines, Plums, and Pears, which must yield an enormous amount of fruit. In September the Pears, trained like Vines, were a "sight," as roped from base to summit with their load of excellent fruit. Half the range on both sides the central path was filled with Chrysanthemums—dwarf plants from 2 to 3 feet high, most of them having ten to twenty bold buds that would produce handsome blooms. They were a credit to all concerned, and would in due course make a grand display. In the wet cold district the plants have to be housed early in September.

The Grapes in the fine range of vineries on the south side of the garden were worth a long journey to see. Crops and bunches magnificent. Black Grapes, such as Hamburgs and Gros Colmans, have been splendid for years, but the soil has been too wet and cold for Muscats, some 4 or 5 feet of rain falling on the outside borders yearly, and it evidently suits the others. Mr. Thomson has found out a way to make it suit Muscats, which were remarkably fine. An interesting and excellent way it is. It has often been said that good Muscats and Black Hamburgs cannot be grown in the same house. They are not only finely grown side by side at Drumlanrig—one rod of Muscats between two of Hamburgs throughout one large house (except where Gros Colmans take the place of Hamburgs), but both are fed by the same roots. Thousands of persons would rejoice to have such noble bunches of the black varieties and the Muscats, even in separate houses, as are here grown in twinship, or tripletship if you like to have it so.

The Muscats alternate with Black Hamburgs, or Gros Colmans as the case may be, are grown in this way. From each Vine planted of the black varieties two fruiting rods are taken, with a third added by grafting of the Muscat of Alexandria. In this way only has Mr. Thomson been able to grow fine Muscats at Drumlanrig. He tried all sorts of stocks, but unless where limbs of the stock were retained the Muscats did little or no good. Nor did they on their own roots, but now he has them to his satisfaction, or at least he ought to be satisfied with them. His theory is, and no doubt the correct one, that the roots are kept working in the cold soil under such a rainfall longer and more actively, and the Muscats share the benefit, the robust helping the delicate variety to do its work. It was worth going to Drumlanrig to see the combination, the problem solved, the fruit of a happy thought, born of scientific reasoning, and another feather in the cap of this grand old gardener of modern times, who has changed little since the portrait was taken as shown in fig. 43.

The second large house is devoted to Black Hamburgs, the bunches and berries from top to bottom of the Vines and from end to end of the house forming such a crop as this poor scribe has not seen during his journeyings of a few thousands of miles. In the

FIG. 44.—A NOVELTY IN GRAPE PRODUCTION. (See page 206.)

third house we find a mixture—Muscats nursed by Raisin de Calabria and by Gros Colman as fine as anyone could wish to see, especially the union of the Muscat and the Colman. Then we were drawn to a monster crop on one Vine—a young rod of Gros Guillaume, often miscalled Barbarossa, established on Gros Colman, probably 5 lbs. per lineal foot. Perhaps, however, the scales may have settled the point by this time, and if so it will be interesting to learn the result. The fourth house in the range was devoted to the combination of Gros Colman and Muscats, probably such a house of Grapes produced in the same way as could not be seen elsewhere. There is only one right word for it—magnificent. The crop of Duke of Buccleuch in another range was cut and gone, but the noble Duke is, as it ought to be, "at home" at Drumlanrig, giving a fine yield of its beautiful and delicious fruit.

The Vines, with perhaps a few exceptions, including "The Duke," were planted by the grower of them over twenty-five years ago. The outside borders are firm and "matted" with roots near the surface. That, with proper nutriment, including moisture, also the best of routine attention, is the secret of their vigour and productiveness. Mr. Thomson did not say so, but there can be no doubt they have had a generous share of the manure with which the family name is identified, but that alone would not suffice. The surface must be kept moist during dry weather in the summer to keep the roots there for appropriating the food supplied. This is effected by mulching, not through the spring months for excluding warmth from the sun, but in summer for preventing evaporation. The reverse of this is very much too common, and then the borders cannot be permeated with myriads of fibres bristling almost through the surface, nor can the Vines be in the splendid condition of those at Drumlanrig.

Before leaving the Grapes a curiosity ought to be noted—perhaps one of the rarest occurrences connected with the Vine. I have seen an Orange grow within an Orange, a small Grape within a berry of a large one, an Apple with a leaf attached produced from the thick stem of a tree, but only at Drumlanrig have I seen a bunch of Grapes issue directly from the old stem of a Vine without any leaf whatsoever. We had to stoop and look under the front slatted stage to examine the phenomenon, but the readers of the *Journal of Horticulture* can see in fig. 44 exactly what it was like without stooping. This ought to suit Mr. Iggulden, who appears to like things “plain and easy.” A latent bud was there, and it is not uncommon for such buds to form on old wood and grow into stems or leaves. The tendril of a Vine is a changed or modified leaf; a bunch of Grapes is, shall we say, an ennobled tendril. But here the order of progression was changed, the bunch coming first and alone. Here is a chance for Mr. Abbey to explain the “reason why,” and the whole metamorphosis. If that word is too much for Mr. Iggulden, I have something simpler explanatory of the strange freak of Nature, and it shall be given to him as it was given to me. Speaking to a gardener on the subject—a plain, good, working gardener—and asking his opinion thereon, he at once replied, “Why the whole thing’s clear enough. Mr. Thomson would only allow so many bunches on the Vine, and nipped all t’others off, but it was so full of fruit inside that it thought it would send out a bunch where he couldn’t see it.” Can Mr. Iggulden improve on that for plainness? Even Mr. Abbey has not gone so far as to suggest that Vines can “think.”

As these sheets are taken as they are written and as fast as they can be got hold of to the printer’s, a little torment has commenced sounding the alarm—“only room for a little more, 5 or 6 inches,” and I wanted to say something about the plants and kitchen garden. Of the plants, then, it is the same now at Drumlanrig as at most other places—only such are grown that are of service for decoration in the Castle and for cutting, but how healthy they are and how clean in their always clean outside-glazed pots! All kinds of plants thrive in these non-porous pots quite as well as in the porous, and much labour is saved in washing by using the former. Mr. Cuthbert Johnson, a scientific cultivator, has used them long and extensively. The late Mr. Woodhead always used them for his Auriculas, and healthier plants were never seen. In these pots less water is needed than in the porous, and consequently less of plant food is washed out of the soil, while when water passes down freely the air follows in quite sufficient amount, and no one can prevent it. The time-honoured assumption that pots must be porous to admit air to the roots of plants is based on a fallacy. When soil is sodden air cannot enter it whether pots are porous or not. When it becomes too dry air enters too freely, but the tormentor is here again asking if I will be so good as to “crush it.”

The same attention is given to the kitchen garden as to any other department at Drumlanrig, and all are equally clean and orderly. The demand for produce during the shooting season is great when the Castle is occupied by about 200 persons. The supply is on a correspondingly large scale, and what would perhaps most arrest the attention of visitors in September was a huge breadth of Ne Plus Ultra Peas, the rows, I know not how many, certainly 9 feet and probably 10 feet high, laden with pods; but a couple of rows of Potatoes would also arrest attention—huge ridges 4 feet apart, and such growth, as if for the purpose of trying what Potatoes could be made to do. They did very well as to bulk, some individual sets giving a yield of 17 lbs., several tubers exceeding 2½ lbs. in weight, but none equalling the tuber weighing 3¼ lbs. in an Archerfield experiment.

Mr. Thomson will leave the scene of his long labours reluctantly. He speaks most highly of the kindness and respectful treatment he has received from the two Dukes and all the members of the family he has served during his long term of responsibility, and dwells with pleasure on his connection with “old pupils” who occupy good positions in this and other countries, and is satisfied that the great garden which he loves, and which will long bear the impress of his skill, will be in the keeping of a most competent successor in Mr. Inglis.

“Pages made up; only space for twenty lines more.” That is the fiat. These must be lines of grateful acknowledgment of the genuine welcome extended to us by Mr. and Miss Thomson during our short and no doubt our last rest in the picturesque home on the terraced brae. All that could be wished for was there, with something to take away to remind us of the all too short but pleasant call—a bunch of Heather. For months it has sparkled in a London den, all through the dreary days that have since passed by, “looking as red and fresh,” to quote the words of a brother of the

pen, Dr. Gordon Stables, in the “Echo,” “as when culled from the braes around Balmoral Castle.

And we love it for lulling us back into dreams
Of the blue Highland mountains and echoing streams,
And of Birchen glades breathing their balm;
While the deer is seen glancing in sunshine remote,
And the deep mellow lush of the wild pigeon’s note
Makes music that sweetens the calm.

That answers equally for Drumlanrig, says the Missus and—
THE SCRIBE.

BRUSSELS SPROUTS.

As a winter vegetable the Brussels Sprout stands without a rival, from the fact that its season of use extends over so long a period, and what is more, few consumers seem to tire of it in the same manner as they do of Broccoli, Parsnips, Seakale, or Cabbage from the frequent and continued repetition. Most, if not all gardeners, have their own particular rule in the matter of routine—sowing, transplanting, site, and distance allowed between the plants and rows, and a good quarter of Brussels on the advent of winter is usually one of the items over which the kitchen gardener prides himself, more or less according to its quality and extent.

There would seem a universal custom among private gardeners to sow their seeds of this crop under glass during the earlier months of the year, and to those who make it an annual custom—and it may have been one extending over many years—it would be utterly futile for anyone to attempt to bring about a change in their methods of procedure. A course which has resulted in a successional and completely satisfactory crop may well be followed without change, and this applies to the man who depends on sheltered open-air borders for the first sowing, equally with the one who depends absolutely on indoor raised plants, sown in boxes or pans. Good crops are produced annually from seeds sown indoors under varying conditions, and the same may be claimed by those who sow their seeds outside the shelter of glass houses or pits.

Only once during the twelve years of which I have had a responsible charge have I sown Brussels Sprouts indoors, and then only a small portion of the crop was so treated, and I did not find the superiority of the one such as to lead me to adopt it as an alternative since, although I must say the numbers required have not been so large as needed in some establishments. At present my annual stock numbers only 2000, but if I had to accommodate half these in boxes it would entail more space and labour than I can well afford to devote to them.

My plan is to sow a portion of the seeds on a narrow border against a sunny wall, where they are naturally sheltered, and where protection can be given easily against birds, and by thinly scattering the seeds on the bed of fine and fairly rich soil I get sturdy plants to put out permanently on ground already in waiting without any necessity of pricking out into boxes or nursery beds. Here they grow freely, and are no further trouble unless slugs set up a claim for a portion, when others must be found to take their places. It is not desirable or attempted to sow and plant the whole at one time, but rather the early one is supplemented by a larger sowing made quite in the open among the early Broccoli, Cabbage, Cauliflowers, and such like. For getting a supply of good Sprouts in February and March it is quite necessary to make a correspondingly late sowing, and there is no doubt as to the value of a late supply. It is an easier matter to secure an early matured batch than to keep up a daily gathering of hard Sprouts during March.

In gardens where there is not much or any accommodation for forcing Beans or Asparagus, and when Broccoli is in evidence only by name, late Sprouts are valuable, for at that season there is but a small choice. Seakale, acceptable as it is in early winter, is not so highly valued generally after it has had a course extending over four or five months.

Varieties ranging in height from 18 inches to 4 feet are available, some bearing large, others small sprouts, and there being so many good selections in the market, and offered by all the leading seedsmen, there is abundant choice to suit all and every requirement. As a general rule the larger the sprout the greater the pleasure given to the grower, and sometimes at the table; but some claim a greater degree of excellence in the small hard sprout than is found in large ones. Much, however, depends on the cook in the matter of flavour when presented at the table—indeed, this applies to most vegetables—and very often complaint is lodged against the quality of Sprouts, whether they are large or small, without any ground whatever.

In good soil 3 feet between the rows of plants is none too much—that is, the larger growing ones, comprising the various exhibition strains; and 2 feet between the plants. At these distances my plants completely furnish the ground, and they invariably set

up their sprouts better when plenty of room is allowed for air and sun to act upon them. Strong plants at 2 feet apart each way become a dense mass of foliage, which absolutely shuts out the sun's rays; but in poorer ground these distances would suffice. Last year the plants languished for want of root moisture, and did not attain to more, and in many cases less than half their usual size; but the stems, though short, became thickly set with good sprouts, even below the soil. There was no rain to do them any appreciable good from the time of planting until September, and it was surprising how well they withstood the ordeal, and the excellence of the crop they bore after that date. If there were benefits derived from indoor sowing, it was more conspicuous last summer than is usually the case, but notwithstanding the gain thus secured, I shall not be tempted to depart from my custom of sowing outdoors in March.—W. S.

CHEMISTRY IN THE GARDEN.

(Continued from page 187.)

THE material of which the sedimentary rocks are formed, was derived first of all from the primary rocks. The first named rocks were formed under water, but as time went on some of them were upheaved by volcanic action, and so became dry land; they in their turn supplying material for the formation of other sedimentary rocks. As some are formed from the primary, and others from the primary and sedimentary, we should in time have many different kinds of rocks upon the earth. To give our readers some idea of the vast changes the rocks have undergone, it is only necessary to say, that if all the different kinds of rocks, which have been formed at various periods since the formation of the earth, were placed on the top of each other, they would reach a height of thirty miles.

As there are so many different kinds of rocks upon the surface of the earth, and as the soil is formed by the decay of these, it naturally follows that soils will vary quite as much as the rocks, and to a large extent the former will have the same characteristic properties as the latter.

THE FORMATION OF SOILS.

The various agents which are at work, breaking and wearing down the rocks into soil, are as follows:—Water, carbonic acid, oxygen, changes of temperature, plant and animal life.

Water is the most active of all the disintegrating agents. It attacks rocks and causes their decay in two different ways—first, chemically; and secondly, physically. When considering the origin of soils, we saw that felspar and mica contained silicates of alumina, potash, soda, lime, magnesia, and iron. Water itself possesses the power to dissolve out some of these constituents when it comes in contact with the surface of the rocks. Rain water as it descends through the air absorbs oxygen and carbonic acid; and water containing these gases attacks the constituents of rocks more energetically than would pure water. The carbonic acid unites with the potash, soda, lime, or magnesia, and forms carbonates of potash, soda, lime, or magnesia, and these substances being soluble in water are dissolved and carried away.

The potash, soda, lime, and magnesia are present in the minerals felspar and mica in chemical combination with silica and alumina. When carbonic acid unites with either of the first-named substances, and water dissolves and carries them away, the silicates of alumina undergo a chemical change. As soon as the potash, soda, lime, or magnesia is taken away from the silicate of alumina water takes its place—i.e., unites with the silicate—and a substance called hydrated silicate of alumina, or pure clay, is formed. Pure clay (kaolin) is the substance which gives to horticultural clays their plastic sticky character. In gardens stiff tenacious clays are sometimes burnt. This is done for the purpose of driving off the water from the hydrated silicate of alumina; the silicate of alumina (burnt clay) left, being sand-like in character, makes the clayey soil to which it is applied more open and porous.

In the mineral angite the magnesia is present in combination with silica. If the magnesia is dissolved out of the mineral only silica (sand) would remain. Hornblende contains large quantities of protoxide of iron (Fe_2O_3), but the substance on being exposed to damp air is oxidised—i.e., unites with oxygen—and becomes the peroxide of iron, or iron rust (Fe_2O_3).

This altering of the chemical composition of the silicates of alumina, the silicate of magnesia, and the protoxide of iron, causes the surface of the rock to become soft or rotten; and the loose particles may either remain to form a film of soil, which will be increased in depth as time goes on, or they may be washed into the ocean to form sedimentary rocks.

Owing to the action of water, carbonic acid, and oxygen the surface of the rock becomes full of tiny holes. When rain falls these will fill with water, and if a frost follows the expansion which

takes place when water is converted into ice causes small pieces of rock to be broken off from the mass. There are very few rocks which do not possess fissures or cracks in them; if these during wet weather get filled with water and it freezes, huge pieces of rock may be separated from its parent. It is owing to this cause that so much rock debris is found lying at the bottom of cliffs.

The disintegrating agents will attack the broken pieces of rock, and gradually convert them into soil. The action of frost in pulverising pieces of rock is well illustrated when pieces of chalk or marl are put on land in the autumn. During rainfall the pieces of chalk or marl get saturated with water, and if a frost follows the expansion of the water as it is converted into ice (9 cubic inches of water become 10 cubic inches of ice) forces the particles of rock apart, and the lumps fall down into a powder as soon as they thaw.

In past ages the action of moving ice (glaciers) in grinding down the surface of rocks into soil was considerable, thousands of acres called *drift* being formed in England by this cause.

There is always a tendency in running water to wash the soil from the hills into the valleys, and during heavy rainfalls a considerable quantity of soil is carried into the ocean. It has been estimated that 1 foot of the whole exposed surface of the earth is carried into the ocean every thousand years. To illustrate this fact, we may say that Professor Geikie has found that the Thames carries 1,865,903 cubic feet of sediment (soil) into the North Sea every year. The Thames is but a small river compared with the Mississippi and the Amazon, for it has been estimated that these two rivers carry annually about 1343 million tons of sediment into the ocean.

The alternating expansion by heat and contraction by cold to which the surface of rocks are exposed, cause the constituent particles to become loosened, and they ultimately break down and form soil.

Lichens and Mosses grow in the film of soil formed on the surface of rocks. When they die they add to this film of soil a certain amount of organic matter, and this substance, as it decomposes, yields carbonic and other acids which attack the constituents of the underlying rock, causing its decay, and thereby deepening the soil. As time goes on there would be sufficient soil formed to support weeds and grasses, and the growth and decay of these plants would soon deepen the soil considerably.

Earthworms are very active agents in the formation of soils. They swallow the earth for nourishment, the swallowed earth being afterwards brought to the surface, and forms the wormcasts. They draw into their holes dead leaves, which they swallow and afterwards excrete in a partly digested form. Their burrows penetrate into the soil sometimes to a considerable depth, and these facilitate drainage, besides allowing the air to penetrate into it.—W. DYKE.

(To be continued.)

COOKING POTATOES.

I SHOULD like to say a word or two on this subject before it is dropped. I consider it a matter of great importance, for it is undoubted that only a small proportion of the cottagers who can grow good Potatoes ever get them really well cooked; and it is probable that not only no vegetable, but few articles of food, show so much difference in value and wholesomeness as badly cooked and well cooked Potatoes.

No, I have got no receipt to put forward, and I do not at all suppose I should be able to do it myself, though I remember gratefully the napkin and wooden bowl of my childhood (mentioned by a correspondent) as bringing before my mind Potatoes that were truly pleasant to the eyes and good for food; but I think that those who do know should use every possible means of bringing before cottagers "how to do it" and "how not to do it," for I am not at all sure that it is not more important even than the combating of the Potato disease itself.

The simplest possible way is a class for boiled Potatoes at cottagers' shows, at which, of course, punctuality in bringing and judging at an appointed time must be strictly adhered to.

In my own village I quite think that this class has done a great deal of good. The first time it was instituted at our cottage show the exhibits showed the need of it as plainly as possible—one dish was a picture, and easily gained first prize. Of course they were tested and tasted. And two or three of the others apparently contained shapeless pieces of yellow soap, as unappetising and unwholesome as possible. The next year the first prizewinner held her own, but there were good second and third, and no very bad ones. And in the third year, or once or twice since, she has been beaten; and last year I could have eaten the lot, and as the hardworked Secretary, and everything else, having missed my luncheon, felt quite capable of it.

How plain it was that, by teaching the wives in this practical way, we had helped the cottagers themselves to a far greater enjoyment of those Potatoes which they grew so well, and gained prizes for in their raw state in the other classes.

Secretaries and committees of cottagers' shows, please note.—W. R. RAILLEM.

HORTICULTURAL HISTORY NOTES.

ALONG LONDON'S NORTHERN HEIGHTS.

RECENTLY a tough fight was fought to preserve intact for the public benefit what yet remains of the old forest of Middlesex near Highgate and Muswell Hill. In various ways the London of our ancestors was advantaged by the extensive woods which crowned the northern heights of the metropolis. Of course they were not near enough to screen the city effectually from the keen winds, but they afforded the Londoners a considerable stock of what was then the chief fuel. Wild fruits and game were obtainable as items of food supply. From the recesses of the woodland arose numerous springs too, which, flowing southward, furnished better water than that taken from the Thames, and refreshed the fields and gardens about the city suburbs. Even now, below the level of sewers and mains, a few of these streams are believed to pursue their course; the ancient Walbrook for instance, which burrows under central London, has been detected by accident. Three rivulets at least passed through Islington and Clerkenwell—the rapid but narrow Fleet, the Oldbourne, and the River of Wells or Turnmill Brook, which joined each other near Holborn Hill to cross Fleet Street on their way to the river.

Probably it is due to the circumstance of not only the north of London, but all its sides, having numerous springs and brooks, that the vicinity was formerly so rich in native species of plants. Something, indeed, must be allowed for the fact that its Flora underwent a more thorough research in bygone years than did that of other English towns. Curious to say, even in last century, before the suburbs were extensively built over, many plants had become scarce, not from the over-zeal of eager botanists, but because they were sought for medicinal purposes, or collected to be placed in gardens. Exotics being scarce, the citizens adorned their gardens with native flowers. A long list of these favourites of our ancestors might be made out. Some of them, by cultivation and crossing, underwent great changes, and became parents of plants which are esteemed not only in Britain, but in other countries. Could we call up a picture to the mind's eye of the gardens cultivated about London by the pioneers of modern horticulture, we should see them numerous in the north, especially at Hoxton, Pentonville, and Clerkenwell, clustering specially in the neighbourhood of the City Road.

It remains on record as a noteworthy fact that citizens who had gardens in this direction were amongst the earliest vendors of vegetables along London streets. They grew, during some seasons, more than they required for themselves, and sent their servants to sell it. This practice is mentioned in records of the fourteenth century, because they sometimes tried to push business near church gates, where people congregated, to the annoyance of the clergy. Besides various vegetables, we read of Cherries being sold, that fruit being much grown then north of London. Strawberries were well known about that date; some think produced in gardens, the Hautboy (*Fragaria elatior*) having been transplanted from copses; it was certainly once a much commoner wild plant than it is now.

We might suppose it was an easy thing four or five centuries ago to carry on gardening about the northern suburbs; such, however, was not the case. Many of the citizens, it is true, had villas scattered here and there in the time of the early Henries, having large gardens attached with numerous trees, most of them exhibiting labyrinths or parterres, as were then fashionable. But these residents did not look favourably upon intruders who wanted to use land for cultivating vegetables, while the London folks generally objected to the enclosure of fields or pastures over which they had freedom to stroll and play games. During the reign of Henry VIII., when some ground at Hoxton and Islington had been fenced for gardening purposes, a mob of angry apprentices turned out with the cry of "Shovels and spades!" They threw down the barriers and filled up the ditches. Indeed, Islington, a promising locality as to soil and situation, seems through such opposition to have been slow in developing market gardens or nurseries. Even for the cows, of which many were fed there, we read that Turnips and Potatoes were brought from a distance which might have been grown on the spot.

Hoxton, the Hogsdon of olden time, once perhaps a resort of pigs, came in advance of Islington. There, in the seventeenth century, were the gardens of Darby, Pearson, and Ricketts. Later on the place was made famous by Fairchild, who had a vineyard and a nursery extending to Kingsland. He was an author and botanist, whose "City Gardener" had much repute. On the edge of Hoxton, and linking Clerkenwell to Shoreditch, was the Old Street Road, celebrated for its flowers and fruit during the reign of Elizabeth, where the poet Daniel had a garden of rarities. At

Clerkenwell there was a vineyard about that date, or earlier, upon a hill rising above one of its streamlets. One of the numerous French emigrants who rendered our horticulture great service settled himself in the neighbourhood of Penton Street; his name was D'Aubigne. The ground became well known as "Dobney's Gardens," and passed through many hands, not being all built over till 1835. It turned to a sort of pleasure garden at last, and in it Wildman, the noted bee tamer, exhibited in 1772 his favourite bees.

Pentonville, a name quite modern, arose from certain fields belonging to a Mr. Penton, now built over, and is used vaguely, applying to a part of Islington; but the original Pentonville belonged to Clerkenwell. Gerard speaks of it as an estate owned by the nunnery and called "Mantells," properly Mandevilles, it having been the gift of that family. It is likely that upon it the nuns had cows and grew some herbs which were of repute then in cookery and physic. When it passed from their ownership after the Reformation fruit trees were planted on part of the land, and various pleasant gardens sprung up about Pentonville adjacent to the New River, upon the beauties of which Charles Lamb, the essayist, dilates, writing to his friend Barton from a cottage in the rural-sounding Colebrook Row. Adjacent to New River Head there was to be seen until lately a well preserved plot of ground, illustrative of the style of the Georgian period.

Islington, when it started nurseries in the eighteenth century, did not obtain such a repute for flowers as belonged to some of the western and southern suburbs, though we do read that Mr. Redmond of that place obtained in March, 1756, half a guinea each for his new Auricula called *The Triumph*, a price which seems to have occasioned surprise. Oldest, probably, of its nurseries was that known as Solimon's nursery of late years, also Barr, Parker, and Watson had nurseries early in this century; but hundreds of acres were under grass till they fell into the hands of the builders. Holloway, too, had only a few market gardens. Its most notable garden was a botanical one, originated by Dr. Pitcairn, who died in 1791. He had only a space of 4 acres, but into this he crowded a great variety of foreign and curious plants.

Kingsland bears a royal name, and was probably a part of the Crown suburban estates. Pepys tells us he went thereabout with his bow to shoot birds before the Civil Wars. The Bassingtons had a nursery here in the reign of Anne, and at the time Loudon described the London gardens it was carried on under the same name. It has now been built over, and also that occupied by Ross's establishment; he had market gardens in addition. To Canonbury belong memories of monkish pioneers in horticulture, for the manor belonged to St. Bartholomew of Smithfield, and the priors grew plants and formed groves for their delectation. The mansion was rebuilt by the last prior, Bolton, who stuck up about the premises his punning device, a bird-bolt or arrow shot through a tun. He much loved gardening, and planted Figs, Mulberries, and other trees, dying in 1532. Descendants of these are still pointed out.

That good old worthy, Abercrombie, we associate with northern London, for there it was he chiefly made his home. All admit that his book was highly instrumental in diffusing a taste for gardening, and showing how it could best be practised; perhaps no other upon the subject has been so long a household word as his "Every Man His Own Gardener." (Perhaps, were he writing it now, he would drop the masculine appellation.) Though Goldsmith promised help in its composition he never gave it, and the honour, for which Abercrombie paid, of the Duke of Leeds' gardener giving it his approval did not add anything to its success. He was one of the many Scotchmen to whom British horticulture is greatly indebted. From an Edinburgh market garden he came to Kew at the age of eighteen, and after a little while there he obtained a situation at Leicester House, then at other places. His first venture on his own account was after marrying; he worked garden ground at Hackney in 1770, whence he brought produce to old Spitalfields Market. Afterwards he went to Tottenham Court, the mansion having become a place of entertainment. He took some of the land adjacent to Tottenham Court and Hampstead Roads, carrying on successfully a seed and nursery business. He had also a place at Newington, in Surrey. Many came to see his collection of exotics, and to buy his choice fruits. It was one of his peculiarities to adorn his garden with pieces of poetry of his own composition. The last twenty years of his life, between 1786 and 1806, were spent in Somers Town.

Hampstead never attained to any repute as a home of nurseries, but it was noted for its hay, though gardeners used to visit Lord Mansfield's house and grounds early in this century to view his display of Rhododendrons and American plants. Rosslyn House was also celebrated. At Highgate James Coel or Cowel had a herb garden about 1560.—J. R. S. C.

FLOWERING TREES AND SHRUBS.

(Concluded from page 183.)

EVERGREEN.

THESE should always be planted to a considerable extent in the formation and remodelling of gardens, because there are various positions where it is undesirable to plant trees which present only bare branches throughout the winter. True it is that there is beauty in leafless twigs, but they are not effective screens during the dull season, and the object in planting is often to hide buildings or unsightly places, as well as to form secluded spots. Both these objects can be secured by the employment of evergreen trees and shrubs, and if a fair proportion of them are showy flowering ones there need be no lack of brightness and variety.

In the southern parts of England *Arbutus unedo* succeeds well, and where it does so it presents a most attractive and unique appearance during the early autumn months, for then its white flowers and large scarlet fruits hang in numerous panicles from shoots well furnished with deep green leaves. Here in the Midlands I have not seen it fruiting, although we have a few large plants which flower annually, and for its flowering qualities alone it is worth growing.
